23. **Cobra Venom.**—Lamb and Hunter report experiments with cobra venom and the administration of toxic substances which when injected subcutaneously produce symptoms of muscle paralysis due apparently to degenerative changes in the motor neurons. Doubtless, it has an effect on other parts of the body, but it seems to have a special action on the nervous system. A certain time seems to be required to cause these changes to develop.

27. **Distribution of Trypanosoma Affections.**—Laveran published last year a map showing the number of countries where trypanosoma affections are prevalent, while nine years ago the list was limited to surra in India. During the last year three new trypanosoma affections have been discovered, two of which are peculiar to man. He reviews them all, with reports of personal experimental research.

28. **Swedenborg's Conceptions of Anatomy and Physiology.**—Neuburger quotes extensively from Swedenborg's work, published in 1740, to prove that he had a remarkably accurate conception of some of the vital processes which are considered a triumph of more recent science.

29. **Razes' "Cure in One Hour."**—The book which Guigues has translated was written by Mohammed ar-Razy, who died in 930, the author of 199 other works. The one with the above title describes a large number of treatments for various affections guaranteed to cure "while you wait." The translator is professor at the French Medical College at Beyrouth, Syria, where the ancient Arabian medical writings are being systematically studied at present. Among Razès' prescriptions we note one for buzzing and noises in the ears as follows: Stir some good opium into water and instill it in the ear. The trouble will vanish immediately. He recommends a certain formula containing pyrethrum and other drugs. One pill taken before meals will suspend epilepsy for a week. For exhaustion from fatigue he advises to anoint the nails with oil, which will give immediate relief. For disturbances in the extremities due to bathing in cold water, he orders the feet to be kept for an hour in hot water to which a handful of salt has been added.

39. *Masculine Dress Reform in the Eighteenth Century.*—The preacher of dress reform to whom Stieda refers was a Dr. Faust of Bückeburg, who published a work on the subject in 1791. He was a scholarly and popular physician, and his book attracted great attention at the time, being translated into French, Dutch and English. The full title was "How to Regulate the Sexual Instinct in Man and Make Human Beings Better and Happier." His theme was a denunciation of trousers. He attributed to this masculine garment all the ills of civilization, and demanded that trousers should not be worn at least until adult age. His plea was that trousers exclude the air and keep the parts in a condition of heat and moisture which acts like a hotbed, forcing the genitalia to premature development and producing unhealthy conditions which favor relaxation and devitalization of the tissues, entailing hyperfunction and inviting disease.

57. **Application of Cold Compress to the Chest.**—Fernet has been advocating for some years the application of a small compress wrung out of cold water in the treatment of congestion of the lungs in infectious diseases. He has found this procedure especially valuable in grippe, typhoid fever,

pneumonia, bronchopneumonia, in congestion with edema of the lung, in incipient hemoptysis, and in certain cases of tachycardia, particularly in exophthalmic goiter. The patients are liable to start and shiver at the first application, but the relief and benefit are soon so marked that they clamor for a repetition. He uses a napkin wrung out of cold water, covered with another folded in four to protect the clothing. He leaves it half a minute and then substitutes another. The total application is thus only one minute. If the procedure is repeated, the compress must be applied at another point, as the impression of sudden cold—which is the stimulating effect on the peripheral nerve terminals sought by the application—soon becomes dulled. He attributes its action to reflex influence on the pneumogastric and on the vasomotor nerves of the sympathetic system. The only contraindication he has discovered in fifteen years' experience with this simple method of stimulation is when the patient is in profuse perspiration, and in his own practice he does not regard this as a contraindication. He cites a case of attacks of dyspnea and palpitations occurring in a young woman subsequent to diphtheria, reported by Duchenne, cured by faradization of the skin. The action of cutaneous faradization seems to him to be exactly similar to that of the cold compress.

59. **Emission of Rays by the Human Organism.**—Charpentier reported at the meeting of the Paris Académie des Sciences, December 14, that phosphorescent and fluorescent substances become more luminous when in proximity to a functioning muscle, nerve or nerve center. He was studying the Blondlot or *n*-rays at the time he made this discovery, and found that it was possible to trace the course of a functioning nerve by this greater luminosity of the fluorescent screen over it. The increase in luminosity was apparent even through interposing substances, except those which are impermeable for the *n*-rays. The rays thus emitted by the human organism reflect and refract like the *n*-rays, and are equally pronounced even after the subject has been in complete darkness for nine hours. This proves that the rays are actually emitted and not merely the effects of stored-up light in the tissues. He was able to determine the outlines of the heart by the changes in the luminosity of a small fluorescent object passed over the region. [The Blondlot or *n*-rays are detected by enclosing a gas jet, for instance, in a metal box impermeable to the heat and light rays. A window of aluminum also arrests the heat and light rays, but allows these *n*-rays to pass. If they are focused by an aluminum lens after having traversed the aluminum window, it will be found that an electric light or a scarcely visible gas flame will shine more brightly under their influence, and phosphorescent or fluorescent bodies become more luminous and active. Aluminum and paper transmit the *n*-rays while filtering out the ordinary heat and light rays, but the *n*-rays are arrested by lead. They are not heat rays, as has been proved by the calorific screen. The evidence indicates that the wave length is far below that of heat and above that of electricity. The *British Medical Journal* of January 2 comments on Charpentier's discovery above, as "opening up possibilities for research on the living body which far surpass anything that the wildest dreams of the imagination have so far suggested." His communication was presented at the meeting of the Paris Académie des Sciences, December 14, 1903.—ED.]

107 Instrument to Facilitate Suture of Lacerations of Vagina and Perineum. M. Stolz (Graz).—Ein Spiegel zur Scheiden-Dammnaht.

**102. Artificial Sterilization.**—Rissmann caused the occlusion of the tubes by cutting a wedge-shaped piece out of each, according to the usual technic. The modification consists in the fact that he operated through an incision in the Douglas cul-de-sac instead of by anterior colpotomy. The technic is much simpler than by the latter route.

**105. After-Results of Placenta Previa.**—Almost three-fourths of Radtke's 80 cases of placenta previa suffered from anemic disturbances subsequent to it. In 53 the anemia could be traced directly to the placenta previa. In 3 previously existing anemia was much aggravated. In another patient who did not exhibit anemia it developed subsequent to a second, normal pregnancy. All complain of weakness, frequent headaches and vertigo. Other patients have exhibited symptoms of a parametritic character, so that of the total 80 fully 61.25 per cent. have been more or less incapacitated for work. His statistics also show that abortion is liable to occur after placenta previa. This was noticed in 23 of the 80 patients, and the abortions recurred several times in 8. His material is reviewed in detail.

113 Ueber das "harte traumatische Oedem" des Hand-Rückens. R. Grünbaum (Vienna). (Commenced in No. 51.)
114 *Phthisis in Gebirge (in mountain regions). E. Fischer.

**108. Disinfection of Hands.**—Braatz gives cuts of his model washstand, in which the flow of the fluid from the jar of alcohol or bichlorid solution above is controlled by a pedal. The jars are high enough so that the arm can be rinsed in the fluid. He also illustrates his folding nail cleaner, or rather scraper, and recommends the use of a small double magnifying glass, such as he always carries with him to inspect his fingers after disinfection to detect any possible lurking places for contamination.

**109. Habituation to Arsenic.**—Hausmann succeeded in conferring a very slight degree of immunity on fowls and dogs by previously treating them with repeated small doses of arsenic. This slight immunity resembles that attained by the Steiermark arsenic eaters, and, like that, is minimal and scarcely beyond the tolerance observed within natural limits. Both the Steiermark arsenic eaters and the animals succumb when larger doses are taken—even when the size of the dose is less than what has been tolerated in certain cases of poisoning. The arsenic is much less toxic apparently in the powder than in solution.

**110. Exanthemata After Injection of Diphtheria Antitoxin.**—Oberwinter describes several cases of what were assumed to be the above, but later proved to be genuine scarlet fever. He emphasizes the fact that the exanthem which develops in the first five days, especially during the third to the fifth day after the injection of serum, should be regarded with great suspicion. In the majority of cases it will prove to be genuine scarlet fever. The first appearance of the eruption at the point of the injection is not a proof of its being a serum eruption, but rather of the contrary, that it is genuine scarlet fever. The cases are generally due to dual infection, before admittance to the hospital, with true diphtheria and true scarlet fever. At the same time he does not deny that a true serum exanthem may assume the form of a scarlatinal eruption.

**112. Hard vs. Soft Paraffin Prothesis.**—Eckstein reviews the literature on the subject of Gersuny's paraffin prothesis, and summarizes that 7 or 8 cases of pulmonary embolism from the use of soft paraffin are on record, with one death, and 2 in rabbits, both fatal. Beside this, there is a case on record of thrombosis of the ophthalmic vein and another of embolism of the centralis retinæ, both terminating in loss of vision in the eye affected. On the other hand, he has never had a single mishap in his 154 cases with possibly 1,000 injections of hard paraffin. He thinks that it is destined to be the normal procedure for umbilical hernia and as a palliative in certain cases of inguinal hernia. In several cases of cleft palate he has improved the speech to such an extent by injection of the hard paraffin into the rear wall of the pharynx that the patients have been able to obtain more lucrative employment. (The technic, etc., were given in The Journal, xl, 1903, pages 64, 613 and 1114.)

**114. Phthisis in the Swiss Mountains.**—Fischer has been studying the carefully kept vital statistics of two Swiss towns of 600 and 1080 inhabitants, the first about 2,500 feet and the second 5,525 feet above the level of the sea. He found that the mortality from tuberculosis during the last twenty years was 7.04 per cent. of the total mortality in the lower, and 3.8 per cent. in the higher town of all deaths during this period. The proportion per 1,000 inhabitants per year is only 1.5 in the former and .74 in the latter. The townspeople say that those who stay at home do not become tuberculous and those who acquire it elsewhere are restored to health on their return.

125 Experts' Testimony in the Konitz Murder Case.—Ueber den Konitzer Mord.

**117. Technic of Forced Feeding.**—Bornstein relates that he has had many patients apply to him after taking a so-called Weir Mitchell course of rest and forced feeding. The cases that had been improved by it were the exceptions. He explains this lack of improvement as due, among other things, to the lack of exercise. The plus in feeding should be accompanied by a plus in exercise, or the cells are unable to take care of the material accumulating. His studies in metabolism have convinced him that albumin alone is what the cells need, and that they must be stimulated by exercise to utilize the supply of albumin, thus crowding out the debilitated elements of the cells with fresh, newly-organized elements. He does not approve of meat for the purpose, considering an oversupply of meat synonymous with gout, but orders casein albumin in some form, such as nutrose, plasmon, sanatogen, or fresh, soft cheese, eggs and buttermilk, much preferring the two first as more inexpensive and convenient. He supplements the albumin with quinin and iron pills and light exercise. The patient retains his freedom, and is not stuffed as if he were being fattened for a fat cattle show. The Weir Mitchell course is indicated in cases of excessive emaciation, in neurasthenia and in cases of wandering kidney in which a support of fat for the floating organ is needed. In all others the simple technic described above is amply sufficient, he believes.

**126. Milk for Infants and Infant Mortality.**—Behring has been continuing his research to discover a practicable means of preserving milk, and describes his numerous experiments and experiences. He has established that formalin will keep milk from souring even in the small proportion of 1/4,000, and that the most sensitive animals take it without apparently detecting the addition of the drug, and persons are unable to tell the milk thus treated from pure milk. Addition of formalin up to 1/500 proved absolutely harmless for all the various animals investigated, whether the milk was ingested per os or injected into a vein or under the skin or into the peritoneal cavity. He further states that by a special technic which he has devised ~~and will soon~~ publish he was able to preserve milk so effectually that it could not be detected from fresh milk when delivered at a distance eight days after the milking. The milk thus preserved was derived from his immunized cows, and his method of preservation did not impair in any appreciable manner the immune bodies contained in the milk. He tabulates the results of tests which showed that addition of 1/10,000 formalin kept the milk from souring for six days. Calves fed on this formalinized milk thrived better than the controls, while prevailing diseases were eradicated by this method of feeding. Not a single case of "Kälbersterben" (calf dying) occurred in one stable in which it had previously been extremely prevalent and invariably fatal. The results observed indicate that formalinized milk is more readily digested than ordinary milk, as it coagulates in delicate flakes. Heating the milk injures the immune bodies, and hence heat sterilization can not be applied to the milk of his immunized cows. (See his articles, THE JOURNAL, xli, pages 1178 and 1266.) Fresh horse serum has a destructive action on anthrax virus, which it loses after six hours. Cow serum does not possess this destructive action on anthrax bacilli nor on streptococci, staphylococci, and certain other bacteria. Reasoning from the fact that young calves are not affected by the colon and lactic acid bacilli, which they must ingest in considerable numbers, Behring surmised that their serum must have antibacterial action for these two varieties of bacteria. This surmise was confirmed by the results of tests which established that the serum and the milk of cattle contain isopathic antibodies for these two varieties. Fresh milk contains a powerful antibody against the colon bacillus, but the proportion is less than that in the blood serum, as the latter contains more of the blood albumin. The same is true in regard to lactic acid bacilli, but to a lesser extent. He is convinced that the antibacterial action of these antibodies is plus that of the formalin in his preserved milk, which is remarkable, as usually the antibacterial action of chemicals is rather antagonistic. ~~He~~ refers to his previous announcements of the unprotected condition of the alimentary canal of infants and young animals owing to the imperfect development of the mucous lining, and comments on the perils to which we expose infants by depriving them of these powerful antibodies in the milk against the colon and the lactic acid bacilli, as the antibodies are destroyed by heating the milk. Jensen has recently reported experiments which showed that boiled milk given to newborn calves for their first meal invariably induced a violent diarrhea similar in every respect to the spontaneous disease known as "Kälberruhr" (calf dysentery). It is immaterial to adults whether they take boiled or unmodified milk, but Behring is convinced that the infant mortality in our large cities is closely connected with the use of heated milk in which we have destroyed the antibodies so sorely needed by the infant organism. In conclusion, he summarizes that he will have accomplished his aim if he can convince families, communities, physicians and local authorities of the fact that when mother's milk is unattainable, the true food for the infant is not heated milk, but pure, unmodified milk from cows absolutely free from the suspicion of tuberculosis. When it is impossible for the infant to obtain the milk direct from the cow, then he is strongly in hope that the new technic of preservation which he outlines here will be found a very important aid in the prevention of infant mortality.

**127. The Healing Art.**—Harnack's article comments on the tendencies of the day and the way to combat quack practices. He uses the untranslatable word "Heilen," which, as he remarks, includes the three Latin verbs mederi (from which medicus) is derived, curare (from cura, care), and sanare (to make well). The physician's task includes the three, and he should not ascribe undue importance to the bacteriologic laboratory. He advocates sending young physicians into the homes of the poor for their "practical year," instead of placing them as fifth wheels in already sufficiently well-equipped hospitals, where they are not needed.

**130. Radiotherapy of Cancer.**—Bruns concludes from a comprehensive summary of what has been published on this subject in America and Europe, as well as his own extensive experience, that the large majority of carcinomata are not amenable to radiotherapy. Those situated near the surface are favorably influenced, but they are not completely cured. Cancroids of the skin alone are capable of being completely cured by radiotherapy. It is particularly valuable as a palliative in inoperable cases of mammary cancer, etc., and the delay for trial of radiotherapy in ulcus rodens is justifiable on account of the slow development and the possibility of complete cure. It should be applied by experts, and the public and physicians should be amply warned not to dally with radiotherapy until the propitious moment for the knife has passed. It has not proved the long-sought remedy for cancer, but it is more important than any other yet advanced, as is evident from inspection of its action on the specific elements of the carcinoma.

**131. Treatment of Eczema.**—Lassar describes his technic for the treatment of eczemas, and concludes with the statement that the Röntgen rays are liable to prove very valuable for the treatment of certain eczemas. They have displayed especial efficacy in cases of chronic eczema of the hand. Even a few applications will abolish the itching, reduce infiltration and render the surface smoother and of a more normal aspect. Persevering treatment has entailed complete and permanent cures.

**132. Immunization of Cattle Against Tuberculosis.**—More than 1,000 head of cattle have been immunized against tuberculosis by Behring's method to date, and the results confirm all his assertions. The vaccine is supplied by a Marburg firm (Dr. Siebert and Dr. Ziegenbein), with full directions. The veterinarians are clamoring for compulsory vaccination of all calves by this method.

142 Ueber die Heberden'schen Knötchen der Finger. O. Rosenbach.

**133. Hernia Into Umbilical Cord.**—Lotheissen describes with cut a case of this rare condition which he remarks is rather a malformation than a congenital rupture, as the intestines do not protrude, but simply have not receded into the abdominal cavity as in a normal fetus. The fissure may extend into the abdominal walls or be confined to the umbilicus, or the hernia may be rather a rupture of Meckel's diverticulum.

Only about 90 cases of these three varieties have been published in the literature during the last twenty years. Surgical intervention is indicated within the first twenty-four hours after birth. Out of 68 cases operated on, 70.6 per cent. of the children recovered without mishap. The intraperitoneal radical operation, he thinks, is the only one to be considered. Narcosis should not be applied unless in exceptionally severe cases with rupture of the hernial sac, as in a case described by Bayer in which 30 gm. of chloroform had to be used. The smaller the protrusion the better the results. Fully 50 per cent. of all the cases in which the liver protruded also terminated fatally.

134. **Sight-Testing Apparatus.**—The test card is enclosed in a box with a slit allowing only one line to be seen at a time. The examiner sits beside the patient and raises or lowers the test card by a string and pulley. The appliance is particularly valuable to detect simulation.

135. **McBurney's Point in Lead Colic.**—Donath relates from Nothnagel's clinic at Vienna a number of examples to show that the tenderness at McBurney's point, supposed to be pathognomonic of appendicitis, is a typical sign of an isolated attack of lead colic or an indication of the onset of a severe exacerbation. In these cases it may be accompanied by colic pains restricted to the right lower region of the abdomen. Also during the subsidence of an attack of lead colic there may be diffuse colic pains and tenderness at McBurney's point without spontaneous pains. This combination rarely occurs at the onset of an attack. During very mild attacks of lead colic the sole clinical sign may be the sensitiveness to pressure of the region, including McBurney's point. There is no doubt that a number of such cases of lead poisoning have been erroneously operated on as cases of appendicitis.

138. **Torsion of Ovarian Hernia.**—Schnitzler states that the case described is the third in which hernia of an infant's ovary was complicated by torsion. There were no severe symptoms on the part of the peritoneum such as are noted in case of torsion of an ovarian tumor in adults. This indicates, he thinks, that the symptoms are not due to the torsion so much as to the irritation from the tumor in the abdominal cavity. An infant's ovary is probably less sensitive to injury than an adult's.

140. **Syphilitic Anemia.**—Samberger explains this condition as the result of the action of the syphilitic poison on the blood corpuscles. It renders them less resistant. Consequently when mercurial treatment is instituted the blood corpuscles are destroyed by the mercury for a time, but soon the effect of the mercury is seen in the improvement in the general condition. As a part of this improvement the corpuscles become more and more resistant and the mercury, which at first had a destructive action on them, ceases to affect them. He thinks that determination of the lesser resistance of the corpuscles will afford insight into the problem whether the syphilitic infection is still restricted to the primary lesion or has already invaded the organism as a whole. He gives the blood findings in 13 cases studied.

141. **Aspiration of Stomach Contents.**—Neumann uses merely a stomach tube and Politzer air bag, and describes the advantages of this combination. In more than 1,000 applications of the stomach tube in this combination he has never had occasion to remove the tube on account of its becoming obstructed. The removal of the air bag from the end of the tube, emptying and replacing it, are easy, simple and generally more cleanly than the use of the funnel from which more or less of the contents is liable to be spilt in the manipulations. The pressure from the air bag is gentle and controllable so that the danger of injury to the stomach wall is reduced to the minimum. The communication issues from Schlesinger's clinic, Vienna.

152 Plastic Operation on Palate with Nasal Septum. O. Föderl—Ueber Gaumenplastik aus der Nasenscheidewand.
153 *Gelatin Hemostasis. L. Moll (Prague).—Die blutstillende Wirkung der G.

143. **Peripheral Constriction of Pulmonary Artery.**—Weinberger comments on the various causes which may induce compression of the peripheral portions of the pulmonary artery, citing extensively from the literature. He mentions among others Kasem-Beck's case of stenosis from compression by a gumma, and v. Schrötter's case, in which both of the main branches of the pulmonary artery were compressed by a metastasis from a locally extirpated uterine cancer. He has observed a personal case in which the physical signs suggested an aneurism or cancer of the descending aorta. The patient was a man of 48, a tavern keeper. The necropsy revealed a carcinoma in the left main bronchus invading the left recurrent nerve and compressing the left pulmonary artery with numerous metastases. The principal physical sign had been a rough, extensive systolic sound heard faintly over the left lung and very loud and rough over the right lung and over the back, its maximum intensity at the right lower margin of the sternum. The sound originating in the main trunk of the pulmonary artery was thus transmitted into the right branch, where the conditions were comparatively favorable for its propagation, while it was arrested in the compressed left branch. He thinks that this sign will enable such a compression to be diagnosed in future.

144. **New Post-Syphilitic Stigma.**—Nobl found the sign he describes in 18 per cent. of 150 syphilitic subjects free from any perceptible manifestations of their disease, that is, in 37 subjects whose infection dated from two to twenty years before. The sign to which he refers is the appearance of the scrotum, indicating atrophy and involution after infectious infiltration. He describes the appearance as an arrangement of the wrinkles on the surface in the form of circles and arcs causing patches of a delicate tracery. The patches are a bluish gray in color and are evidently the result of regressive metamorphosis, and may prove useful in establishing a retrospective diagnosis.

145. **Mistakes in Exercise Therapy of Tabes.**—Frank styles Frenkel's introduction of exercises into the re-education of tabetics as one of the most important achievements of recent years. But at the same time, he says, when it is done without due regard to the pathologic conditions, it frequently does more harm than good. Exercising until exhausted is a frequent fault whose consequences are an aggravation of the condition. He also points out that the chief aim should be to re-educate the trunk, not the legs. Exercises done with the subject reclining merely fatigue without doing the least good. He even suggests that the aggravation which may result from unskillful application of exercise therapy might render the physician liable to pecuniary damages as a thoughtless application of this method of treatment may come under the legal definition of malpractice.

150. **Reducing Size of Nose.**—Gersuny recently operated on a young actor with an unduly prominent nose by resecting part of the framework of the nose through the septum mobile, not disturbing the skin at all. The technic followed is described in detail, with cuts.

151. **Total Extirpation of Hypertrophied Prostate.**—Zuckerkandl gives an illustrated description of his technic and of 13 cases operated on. He also reviews the indications and contraindications for radical intervention. He operated on 8 patients by the perineal route and the results were the restora-

tion of normal micturition in every instance. The lower the prostate and the more prominently it protrudes, the easier it is removed by this route. Diffuse enlargement with the upper margin of the prostate not accessible to palpation, affords much less favorable conditions for intervention. He works through an arc incision in front of the rectum, pushing back the rectum with a broad spatula fastened to the table, which lifts up the prostate. He then slits the capsule and removes the lobes by blunt dissection. The hemorrhage is trifling. His experience with suprapubic prostatectomy was disastrous in the 2 cases in which he attempted it, both patients succumbing to sepsis. The danger of hemorrhage by this route is also great.

153. **Gelatin Hemostasis.**—Moll tabulates the results of extensive experimental research on rabbits and dogs to determine the action of gelatin on the coagulating of the blood. He finds that external application aids in checking hemorrhage by agglutinating the corpuscles. Injected subcutaneously it aids in the production of fibrinogen.

166 Abnormal Chorda Tendineæ in Human Heart. I. F. Pozhariski.—O strunakh v serdtzye tchelovyeka.

154. **Irresistible Movements in Focal Brain Affections.**—Muratoff gives the clinical course and postmortem findings in a case which he thinks sustains his previous announcements in regard to the dependence of the uncontrollable movements on the destruction of the system of cerebellar peduncles. The character of the movements differs from that of cortical contractions in both the clinical and anatomic aspect, as he shows by cuts and analysis of his own experience and that of others published in the last few years.

156. **Sarcoma in Retained Testicle.**—The patient whose case is described by Shevandin was 33 years old. He had noticed pain in the right abdomen for several months and the development of a tumor. Shevandin has found 15 similar cases on record, the nature of the tumor varying. The clinical diagnosis in his case was sarcoma of mesentery and retained testicle, confirmed by an exploratory laparotomy. The patient was too weak for further intervention and died not long after. The findings are described in detail, with cuts.

160. **Cytodiagnosis of Exudates.**—Jacobsohn's observation of 14 cases has convinced him of the great value of cytodiagnosis for the differentiation of exudates. His experience has confirmed in every respect the announcements of Ravault and Widal in regard to the certainty of tuberculous infection when a serous or sero-fibrinous exudate contains lymphocytes and red corpuscles alone. This applies both to pleuritic and ascitic exudates. Inoculation of guinea-pigs always resulted in tuberculosis when the exudate was of this character and otherwise not. These findings were also always corroborated postmortem. Neutrophile cells predominated in the exudate in 2 cases of empyema of the pleura. In one case of cirrhosis of an atrophied liver the exudate contained merely polynuclears and endothelial cells, and no traces of tuberculosis could be discovered at the necropsy. He, therefore, in conclusion commends the method of cytodiagnosis as an important aid for differentiation of pleuritic and other exudates by the general practitioner.

161. **Recovery with Lung Cavities and Heart Defect.**—The patient in this case was a woman of 48, and several physicians confirmed the diagnosis of chronic pneumonia with cavities, and febrile exacerbations, night sweats, extreme emaciation and edema of the limbs and other evidences of mitral insufficiency and stenosis of the left auriculo-ventricular opening. The dyspnea was so pronounced that it not only prevented sleep, but also interfered with speaking and swallowing. The condition was the outcome of constantly progressing illness during a series of years. As the anticipated speedy dissolution did not follow, the patient was taken away from the clinic by her friends, the only advice given her being to "live on milk." She returned four months later in good health and spirits. She had been taken by her brother to his home in the country—carried on a bed in a wagon—and took no medicines but progressive quantities of milk, the maximum finally reached being a "half a pail" a day. Examination of the lungs showed absolute dulness over the sites of the former cavities, with bronchial breathing and no râles. The heart was working in a state of perfect compensation. Two years later Otradinski had occasion to carry this same patient through an attack of articular rheumatism, from which she rapidly recovered.

162. **Internal Treatment of Gonorrhea.**—Reissner commends the favorable action of gonosan, a combination of oil of santal and kava-kava, as an internal remedy in gonorrhea. He has used it in 35 cases and found that it materially improved the distressing symptoms, especially the desires to urinate and painful erections, while the pus became liquefied. The only exceptions to this beneficial action were in cases of chronic cystitis.

163. **Diabetes Insipidus in Children.**—Popoff states that 10 cases of this affection in children have been published in Russia, with 6 of diabetes mellitus. He describes 2 additional cases of the former and remarks that the maximum duration has been six years. An inherited nervous predisposition was evident in about half of the cases. In 2 there had been a preceding trauma affecting the head, with epileptic seizures. The age ranged from 18 months to 14 years. In treatment he gave valerian, Fowler's solution and quinin. The prognosis is favorable in general. In 4 out of the 12 cases the improvement was marked and permanent, but a favorable environment is an important factor in recovery.

183 *Actinomycosis of Lachrymal Duct. M. I. Auerbach.—Gribkovie sleznykh canaltzev. (Commenced in No. 26.)

167. **Typhoid Bacilli in Roseola.**—From the positive findings in a number of cases Kazarinoff regards the roseola patches as the result of inflammation of the skin due to invasion of the lymphatics of the papillary layer by the typhoid bacilli.

169. **Talma's Operation in Malarial Ascites.**—Finkelstein reports from the city hospital at Batoum a case of severe malaria distinguished by extensive ascites as well as spleen enlarged to 20 by 30 cm. in its longest diameters.. After failure of other measures he removed the spleen and performed a typical Talma operation, hoping to cure the ascites. The results were eminently favorable, although arsenic and quinin were needed at first. The patient soon regained complete health. He refers to twenty Russian authors who have reported excellent results from ablation of the spleen in malaria, with no mortality. The combination with Talma's operation, however, is original with him, he believes.

171. **Important Role of Nerves of Taste in Digestion.**—Borisoff has been carrying on research at Odessa along the lines of Pawlow's studies of the digestion. The fresh secretion of gastric juice during sham feeding is due to the action of the particles of food on the nerves of taste causing, by reflex influence, this secretion in the stomach. The mucous membrane of the mouth and throat responds to stimuli in this line in the same specific manner as that of the stomach. Pawlow attributes these secretions in the digestive tract during sham feeding to a psychic factor—the so-called "appetite gastric juice," but Borisoff is convinced that they are the result of reflex action from the influence of the different elements of the food on the nerves of taste. His studies were conducted on dogs, and he gives the particulars of the tests with diagrams.

173. **Adrenalin as a Remedy for Internal Hemorrhage.**—Simonovitch found that dogs and rabbits tolerated large doses of adrenalin by the mouth without general effects. Human subjects also took five times the usually accepted largest therapeutic dose without showing any general effects, not even a single subjective symptom. No general effects were observed in the animals even after the intestines had been intentionally injured. Absorption of adrenalin into the blood through the mucous membrane of the alimentary canal must, therefore, be a very slow process. The inference is obvious that it can be ingested with impunity, and hence may be found extremely valuable in case of internal hemorrhage. Its local action as an internal hemostatic will be enhanced by giving it in small, repeated doses rather than single large ones. The animals in his tests took .015 to .03 gm. and the human subjects five times the usual dose of .01 gm. He made comparative tests with potassium iodid which passed into the urine in half an hour, while the adrenalin could not be detected in the blood. The general effects were realized only when the adrenalin was injected directly into a vein. This is allowable to revive the heart only in desperate cases as a last resort, owing to the danger of paralysis of the heart, which occurred in a number of his experiments on animals.

174. **Syphilitic Icterus.**—After excluding other causes for the obstinate icterus, notwithstanding the denial of syphilis by the patient, Geisler instituted antisyphilitic treatment. The complete recovery confirmed his diagnosis.

177. **Movable Kidney.**—Janovski agrees with the Russian writers, Volkoff and Delitzin, that the varying size and shape of the fossa in which the kidney rests is the cause of its movability in some persons. He does not advocate operating except where palliative measures have failed and the symptoms are referable to the kidney alone. When there is a nervous foundation for the disturbances he advises as an adjuvant to the usual treatment for neurasthenia, the wearing of a special pad, fastened to the corset, to push the kidney into place.

178. **Syphilitic Polyarthritis.**—Willanen's patient exhibited what seemed to be multiple articular rheumatism except for the absence of fever, the gradual onset, and the resistance to the salicylates. Mercury and potassium iodid combined soon induced a complete cure.

179. **Relations Between Taste and the Needs of the Organism.**—Borisoff continuing his research mentioned above, has confirmed anew the close relation between the appetite and the needs of the organism at various times. The food must appeal to the palate in order to stimulate by reflex action the digestive secretions farther along the digestive tract, that they may be ready to act effectively on the food as it reaches them. The cravings of pregnancy and children's love of candy are evidences of this adaptation of the appetite to the needs of the body. The heat radiation of children and their active exercise call for an exceptional supply of carbohydrates. The benefits of salt to cattle and the larger amount craved by man on a vegetable diet are further testimony to this law. He experimented on fowls and found that the roosters did not eat lime, and that the hens ingested a certain average amount of lime, some days more, others, less, but keeping the weekly average at a constant figure.

180. **Value of Palliative Hypnosis in Incurable Organic Disease.**—Pyevnitzki reports from Bechterew's clinic 7 cases of various organic nervous affections immeasurably benefited, from the subjective standpoint, by therapeutic hypnosis. One was a case of syringomyelitis, others of meningomyelitis, etc. He adds that hypnotic suggestion in these cases not only relieves the patient but saves him from resorting to charlatans.

181. **Suture of Bladder After High Lithotomy.**—Rozanoff describes 24 cases, in which he performed suprapubic lithotomy. Except in presence of contraindications such as severe cystitis, laceration or uncontrollable hemorrhage from the bladder, he prefers to suture the wall, using absorbable catgut or reindeer tendon for the lower tier, and not passing the needle through the mucosa. His results have confirmed his opinion of the value of immediate suture of the bladder, but he ascribes great importance to his practice of thorough evacuation of the intestines as a preliminary measure, chloroform anesthesia, and injection of boric acid into the bladder afterward. In all his patients thus treated the wound healed without mishap, except in one instance.

183. **Actinomycosis of Lachrymal Dust.**—Auerbach reviews the literature on the subject of fungous affections of the lachrymal duct and relates the particulars of a case personally observed.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

AN ATLAS OF HUMAN ANATOMY, for Students and Physicians. By Carl Toldt, M.D., Professor in Anatomy in the University of Vienna. Assisted by Professor Alois Dalla Rosa, M.D. Translated from the Third German Edition and Adapted to English and American and International Terminology. By M. Eden Paul, M.D., Brux., M.R.C.S., L.R.C.P. Second Section C. Arthrology. (Figures 378 to 489 and Index.) Cloth. Price, $1.75. New York: Rebman Company. 1903.

TRYPANOSOMA AND TRYPANOSOMIASIS, with Special Reference to Surra in the Philippine Islands. By W. E. Musgrave, M.D., Acting Director Biological Laboratory, and Moses T. Clegg, Assistant Bacteriologist, Biological Laboratory. From the Department of the Interior. Bureau of Government Laboratories. Paper. Pp. 248. Manila: Bureau of Public Printing. 1903.

### PERITONEAL SALINE INFUSIONS IN ABDOMINAL OPERATIONS.

A COMBINED CLINICAL AND LABORATORY STUDY OF THEIR EFFECTS.*

JOHN G. CLARK, M.D.
Professor of Gynecology in the University of Pennsylvania,
AND
CHARLES C. NORRIS, M.D.
Instructor in Gynecology in the University of Pennsylvania.
PHILADELPHIA.

*(From the William Pepper Laboratory of Clinical Medicine, Phoebe A. Hearst Foundation.)*

At the St. Paul session of the American Medical Association we presented a paper[1] on "The Practical Application in Abdominal Surgery of Scientific Investigations Concerning the Function, Anatomy and Pathology of the Peritoneum," in which the employment of infusions of normal saline solution into the peritoneal cavity after all abdominal operations was advocated. The theory as to its value was based on the proved physiologic fact that there are well-defined currents which waft minute bodies from the lower or more dependent part of the peritoneal cavity toward the diaphragm, through which they gain entrance into the retroperitoneal lymph channels, and thence into the general blood channels. Our experimental work, at that time, had been confined solely to tracing the course of minute innocuous granules, such as India ink and carmine, from the peritoneal cavity into their more remote places of lodgment. This series of experiments unquestionably demonstrated that any foreign material in a finely divided granular state will be transported quickly from the peritoneal cavity; and in some instances, within eight hours, these minute bodies were found deposited in the marrow of the long bones, such as the femur and humerus. They were likewise found in the kidneys, liver, lungs, intestines, and even in the gall bladder in considerable numbers. From these observations we reached the conclusion that not only the kidneys, but likewise the liver, intestines, and even the lungs participated in the elimination of these granules. The employment of saline infusions in the peritoneal cavity is not a novel suggestion, but has been the subject of many active discussions, for it has been earnestly advocated by some surgeons and strongly deprecated by others. From the clinical standpoint we have very closely studied this question for the last five years, and have every reason to extend rather than to limit its employment.

In presenting the results of our experiments at the St. Paul session we recognized discrepancies in our own work, in that we had not yet had sufficient time to carry out, with lethal micro-organisms, experiments analogous to those which we had conducted with innocuous foreign particles. It is the object of this paper to detail the experimental work conducted along the latter line.

Certain general principles which have been established by the combined work of many observers are worthy of restatement before we take up the review of our laboratory and clinical observations. When infectious micro-organisms are introduced into the peritoneal cavity, the lymph and leucocytes which are normally present as a circulating peritoneal medium at once assume a combative rôle. An immediate increase of leucocytes is noted (temporary leucocytosis); but after a few minutes these are transported into the general lymph paths and for a short space of time there is a marked deficiency of leucocytes (leucopenia). Then an exaggerated peritoneal leucocytosis is noted, the intensity of which is in direct proportion to the degree of the irritation. Thus a very irritating fluid, such as turpentine or glycerin, may give rise to so profuse an exudation of serum and escape of leucocytes from the blood vessels into the peritoneal cavity as to actually cause the animal's death through excessive depletion.

In experimental infections of the peritoneum, the index of lethality may be judged by the varying degrees of leucocytosis. Thus an excessive degree of leucocytosis followed by a rapid decrease with increasing gravity of symptoms indicates that the toxicity of the micro-organisms has overcome all phagocytosis or germicidal action of the blood serum, and that there will be a fatal result. Not only on the quick delivery into the peritoneal cavity of serum and leucocytes, but also on their rapid exit depends the safety of the patient in the first stages of peritoneal infection. There are no blood vessels within the body capable of such quick action in this physiologic function as those circulating in the omentum, which hangs as a movable, dependent apron over the intestines. Ramifying in all directions throughout this apron are widespread capillary anastomoses of extremely thin-walled vessels, which provide the best anatomic conditions for the rapid escape of leucocytes and serum into the peritoneal cavity.

If there is this excessive peritoneal leucocytosis after an infection, or from traumatic or chemical irritation within the abdominal cavity, the blood examination after an abdominal operation should serve as an indicator of this phenomenon. Already clinical observations have proved the constancy of the increased leucocytosis after even a minor abdominal operation. A very careful and systematic series of observations has been made

182 (No. 27.) Rôle of Internal Organs in Production of Immunity. S. I. Goldberg-Zlatorogoff.—Ob utchastii, etc.
183 *Actinomycosis of Lachrymal Duct. M. I. Auerbach.—Gribkovie sleznykh canaltzev. (Commenced in No. 26.)

167. **Typhoid Bacilli in Roseola.**—From the positive findings in a number of cases Kazarinoff regards the roseola patches as the result of inflammation of the skin due to invasion of the lymphatics of the papillary layer by the typhoid bacilli.

169. **Talma's Operation in Malarial Ascites.**—Finkelstein reports from the city hospital at Batoum a case of severe malaria distinguished by extensive ascites as well as spleen enlarged to 20 by 30 cm. in its longest diameters. After failure of other measures he removed the spleen and performed a typical Talma operation, hoping to cure the ascites. The results were eminently favorable, although arsenic and quinin were needed at first. The patient soon regained complete health. He refers to twenty Russian authors who have reported excellent results from ablation of the spleen in malaria, with no mortality. The combination with Talma's operation, however, is original with him, he believes.

171. **Important Role of Nerves of Taste in Digestion.**—Borisoff has been carrying on research at Odessa along the lines of Pawlow's studies of the digestion. The fresh secretion of gastric juice during sham feeding is due to the action of the particles of food on the nerves of taste causing, by reflex influence, this secretion in the stomach. The mucous membrane of the mouth and throat responds to stimuli in this line in the same specific manner as that of the stomach. Pawlow attributes these secretions in the digestive tract during sham feeding to a psychic factor—the so-called "appetite gastric juice," but Borisoff is convinced that they are the result of reflex action from the influence of the different elements of the food on the nerves of taste. His studies were conducted on dogs, and he gives the particulars of the tests with diagrams.

173. **Adrenalin as a Remedy for Internal Hemorrhage.**—Simonovitch found that dogs and rabbits tolerated large doses of adrenalin by the mouth without general effects. Human subjects also took five times the usually accepted largest therapeutic dose without showing any general effects, not even a single subjective symptom. No general effects were observed in the animals even after the intestines had been intentionally injured. Absorption of adrenalin into the blood through the mucous membrane of the alimentary canal must, therefore, be a very slow process. The inference is obvious that it can be ingested with impunity, and hence may be found extremely valuable in case of internal hemorrhage. Its local action as an internal hemostatic will be enhanced by giving it in small, repeated doses rather than single large ones. The animals in his tests took .015 to .03 gm. and the human subjects five times the usual dose of .01 gm. He made comparative tests with potassium iodid which passed into the urine in half an hour, while the adrenalin could not be detected in the blood. The general effects were realized only when the adrenalin was injected directly into a vein. This is allowable to revive the heart only in desperate cases as a last resort, owing to the danger of paralysis of the heart, which occurred in a number of his experiments on animals.

174. **Syphilitic Icterus.**—After excluding other causes for the obstinate icterus, notwithstanding the denial of syphilis by the patient, Geisler instituted antisyphilitic treatment. The complete recovery confirmed his diagnosis.

177. **Movable Kidney.**—Janovski agrees with the Russian writers, Volkoff and Delitzin, that the varying size and shape of the fossa in which the kidney rests is the cause of its movability in some persons. He does not advocate operating except where palliative measures have failed and the symptoms are referable to the kidney alone. When there is a nervous foundation for the disturbances he advises as an adjuvant to the usual treatment for neurasthenia, the wearing of a special pad, fastened to the corset, to push the kidney into place.

178. **Syphilitic Polyarthritis.**—Willanen's patient exhibited what seemed to be multiple articular rheumatism except for the absence of fever, the gradual onset, and the resistance to the salicylates. Mercury and potassium iodid combined soon induced a complete cure.

179. **Relations Between Taste and the Needs of the Organism.**—Borisoff continuing his research mentioned above, has confirmed anew the close relation between the appetite and the needs of the organism at various times. The food must appeal to the palate in order to stimulate by reflex action the digestive secretions farther along the digestive tract, that they may be ready to act effectively on the food as it reaches them. The cravings of pregnancy and children's love of candy are evidences of this adaptation of the appetite to the needs of the body. The heat radiation of children and their active exercise call for an exceptional supply of carbohydrates. The benefits of salt to cattle and the larger amount craved by man on a vegetable diet are further testimony to this law. He experimented on fowls and found that the roosters did not eat lime, and that the hens ingested a certain average amount of lime, some days more, others, less, but keeping the weekly average at a constant figure.

180. **Value of Palliative Hypnosis in Incurable Organic Disease.**—Pyevnitzki reports from Bechterew's clinic 7 cases of various organic nervous affections immeasurably benefited, from the subjective standpoint, by therapeutic hypnosis. One was a case of syringomyelitis, others of meningomyelitis, etc. He adds that hypnotic suggestion in these cases not only relieves the patient but saves him from resorting to charlatans.

181. **Suture of Bladder After High Lithotomy.**—Rozanoff describes 24 cases, in which he performed suprapubic lithotomy. Except in presence of contraindications such as severe cystitis, laceration or uncontrollable hemorrhage from the bladder, he prefers to suture the wall, using absorbable catgut or reindeer tendon for the lower tier, and not passing the needle through the mucosa. His results have confirmed his opinion of the value of immediate suture of the bladder, but he ascribes great importance to his practice of thorough evacuation of the intestines as a preliminary measure, chloroform anesthesia, and injection of boric acid into the bladder afterward. In all his patients thus treated the wound healed without mishap, except in one instance.

183. **Actinomycosis of Lachrymal Dust.**—Auerbach reviews the literature on the subject of fungous affections of the lachrymal duct and relates the particulars of a case personally observed.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

AN ATLAS OF HUMAN ANATOMY, for Students and Physicians. By Carl Toldt, M.D., Professor in Anatomy in the University of Vienna. Assisted by Professor Alois Dalla Rosa, M.D. Translated from the Third German Edition and Adapted to English and American and International Terminology. By M. Eden Paul, M.D., Brux., M.R.C.S., L.R.C.P. Second Section C. Arthrology. (Figures 378 to 489 and Index.) Cloth. Price, $1.75. New York: Rebman Company. 1903.

TRYPANOSOMA AND TRYPANOSOMIASIS, with Special Reference to Surra in the Philippine Islands. By W. E. Musgrave, M.D., Acting Director Biological Laboratory, and Moses T. Clegg, Assistant Bacteriologist, Biological Laboratory. From the Department of the Interior. Bureau of Government Laboratories. Paper. Pp. 248. Manila: Bureau of Public Printing. 1903.

PORTFOLIO OF DERMOCHROMES. By Professor Jacobi, of Freiburg im Breisgau. English Adaptation of Text by J. J. Pringle, M.B., F.R.C.P., Physician to the Department for Diseases of the Skin at the *Middlesex Hospital, London.* Volume II. Leather and Cloth. Pp. 181. Price per set, $15.00. New York: Rebman Company. 1903.

TRANSACTIONS OF THE NATIONAL ASSOCIATION OF UNITED STATES PENSION EXAMINING SURGEONS. Second Annual Meeting, Washington, D. C., May 13 and 14, 1903. Including an Account of First Meeting at Saratoga Springs, June 9, 1902. Vol. I. Cloth. Pp. 215. Rochester, N. Y.: Published by the Association. 1903.

TRANSACTIONS OF THE AMERICAN MICROSCOPICAL SOCIETY. Edited by the Secretaries. Twenty-fifth Annual Meeting held in Pittsburg, Pa., June 27 and 28, 1902. Vol. XXIV. Paper. Pp. 197. Lancaster, Pa.: New Era Printing Co. 1903.

BACTERIA, YEASTS AND MOLDS IN THE HOME. By H. W. Conn, Ph.D., Professor of Biology in Wesleyan University, Middletown, Conn. Cloth. Pp. 293. Price, $1.00. Boston and London: Ginn & Co. 1903.

TRANSACTIONS OF THE MEDICAL SOCIETY OF NEW JERSEY, 1903. Cloth. Pp. 439. Newark, N. J.: L. F. Hardham Printing Co. 1903.

One case of obstruction and two of empyema were omitted from this table, as in the two latter animals infection had probably occurred previous to operation; in the obstruction case, cultures were sterile. In every case the autopsy was made as soon as possible after the death of the animal, usually within two to five hours.

A stock culture of the micro-organism (*Staphylococcus pyogenes aureus*, described above) was made and used throughout; this culture was plated from time to time, to insure freedom from mixed infection. The method of preparing a culture was as follows: Two test-tubes containing sterile bouillon were inoculated from the stock culture. These were placed in the incubator for forty-eight hours, by which time the culture would be decidedly cloudy. In all cases in which a pair of rabbits (one test and one control) was used, an effort was made to procure animals as near the same weight as possible. Only healthy looking rabbits were selected. Ether was administered at each injection, so as to simulate, as much as possible, an actual operation and also to prevent any unnecessary suffering of the animal.

*Method of Operation.*—The lower part of the abdomen was shaved and cleaned with green soap, alcohol, ether and bichlorid of mercury solution. The syringe and needle were boiled and cooled in sterile water. The amount of culture to be injected was measured in a sterile pipette, diluted with 4 c.c. of water, and injected into the peritoneal cavity, care being taken not to wound the intestines, omentum or other organs. In cases in which the salt solution was used, 100 c.c. were introduced through the same canula. A collodion dressing was applied over the seat of the puncture. The animals were carefully marked and placed in large boxes, with plenty of fresh food and water and the greatest care was observed to make the animals as comfortable as possible after the operation.

### SUMMARY OF POSTMORTEM FINDINGS.

The following diagnoses were made at autopsy on the test animals:

R. 2. S. Early fibropurulent peritonitis, mixed infection.
R. 3. S. Fibrinous peritonitis, mixed infection.
R. 5. S. Obstruction of large intestine. Localized abscess in abdominal wall, walled off from peritoneum.
R. 6. Toxemia.
R. 7. General infection. Pneumonia, abscess in both kidneys, general purulent peritonitis.
R. 9. Pneumonia (double); possible fibrinous peritonitis.
R. 12. General fibropurulent peritonitis.
R. 15. Toxemia.
R. 16. General fibropurulent peritonitis, mixed infection.
R. 18. General infection?
R. 19. General purulent peritonitis.
R. 20. Right-sided empyema.
R. 21. Similar to 20.
R. 22. Fibropurulent peritonitis.

Microscopic preparations were made from the different organs. Cloudy swelling was almost invariably found in the liver, spleen and kidney; in general, however, this was not marked. The lungs were usually congested, and it was not uncommon to find red blood corpuscles in the alveolar spaces. In some instances, micro-organisms were found in the stained tissue.

From this review of our experimental work the evidence is conclusive that a large percentage of the animals in which the normal salt solution was injected immediately after the bouillon culture of *Staphylococcus aureus* was saved by this means.

It has been asserted that the distribution of infectious matter within the peritoneal cavity is not only valueless but very dangerous. From a clinical standpoint we have amply proved that the latter statement is ungrounded; for in a series of 254 laparotomies, in which peritoneal infusions were very largely employed, only seven deaths occurred.[3] In one, a case of general miliary tuberculosis of the peritoneum, death occurred two months after the operation from a general involvement of the lungs and other organs of the body. The second was a case of cancer of the cervix, in which panhysterectomy was performed; no salt solution was used as the pelvic diaphragm was not completely closed, and therefore the solution would not be retained. In this case, the patient died within twenty-four hours after the operation from pulmonary emboli. The third was a general purulent peritonitis; the patient was *in extremis* at the time of the operation, which was hastily performed in the vague hope that she might be saved. Death occurred, however, before the patient reached the hospital ward. In the fourth, a case of general cancer of the peritoneum, only an exploratory laparotomy was performed. No infusion was employed because the peritoneum was already overtaxed and unable to free itself of ascetic fluid. This patient died one week later from the general progress of the disease.

As will be seen from the brief statement of these four cases, the use of the salt solution had nothing whatever to do with the death, for in two of the cases it was not used, and in the other two in which it was employed no ulterior effect could be ascribed to it; for the patient suffering from general tuberculosis survived for two months after the exploratory incision, and the second expired on the operating table.

The three remaining cases were as follows: in one, a patient suffering with a large cystic myoma, death occurred within twenty-four hours after the operation from a virulent fulminating streptococcic infection. This case showed the most intense toxic symptoms and death came with the rapidity which is so characteristic of this fatal poison. In this case, certainly the salt solution in no way retarded the progress of the symptoms. This case also proves the point which we have insisted on, namely, that given a virulent streptococcic infection, in some instances practically nothing which we know of can save the patient. In the next case, the patient was operated on for chronic appendicitis, with extensive adhesions, and right-sided salpingitis; death occurred on the fourth day from intestinal ob-

---

[3] These were as follows:
Myomectomy, 4.
Hysteromyomectomy, leaving ovaries, 26.
Hysteromyomectomy with salpingo-oöphorectomy, 4.
Hysterecto salpingo-oöphorectomy, 7.
Panhysterectomy, 10.
Bilateral salpingo-oöphorectomy for pyosalpinx, 18.
Unilateral salpingo-oöphorectomy, 37.
Suspensio-uteri with operation on adnexa, 25.
Suspensio uteri with plastic operation on cervix or vagina, or both, 53.
Suspension alone or combined with Webster's operation alone, 26.
Gall-bladder operations alone or combined; if combined, included above as well, 4.
Exploratory laparotomy or laparotomy and drainage, 16.
Relief of adhesions, 2.
Appendectomy alone, 9.
Appendectomy combined with other peritoneal operations, 37.
Hernia alone or combined with other peritoneal operations, 14.
Kidney operations alone or combined with other peritoneal operations, 4.
Laparotomy, etc., including inguinal colostomy, etc., 3.
Total number of laparotomies, 254.
Total number of deaths, 7.

In this list of operations only those performed in the Hospital of the University of Pennsylvania have been drawn on for conclusions; for here our conditions were always uniform and the cases were under our constant observation. Were we to have tabulated the large number of operations performed in the St. Agnes, Bryn Mawr and Presbyterian hospitals the mortality statistics would have been about the same.

# THE PHYSIOLOGY OF THE SYMPATHETIC IN RELATION TO THE EYE.*

G. E. DE SCHWEINITZ, A.M., M.D.
PHILADELPHIA.

[Dr. de Schweinitz reviewed the entire literature pertaining to the subject, and from this review and the various opinions of the authors quoted thought the following conclusions might be drawn:]

1. Although *lachrymal secretion* may be caused by excitation of the sympathetic, and increased lachrymation by section of the cervical sympathetic or removal of the superior cervical ganglion, the sympathetic itself should not be considered the nerve of secretion for the lachrymal gland.

2. Dilatation of the pupil is probably caused by contraction of a set of radially arranged muscular or contractile fibers, the so-called dilatator pupillæ, which is supplied by the sympathetic, and by inhibition of the sphincter of the iris. The *dilating impulse transmitted to the iris passes* through the cervical sympathetic and in general terms along the mydriatic tract of the pupil, which proceeds from a center in the medulla as far as the second dorsal nerve, follows its communicating branch to the cervical sympathetic, and *arrives at the internal* carotid plexus, from which point it passes to the nasociliary branches of the nasal nerve, which as the long ciliary nerves supply the muscular tissue of the iris.

3. Although *experimental and clinical evidence favors* the presence of a center situated between the spinal cord and the exits of the sixth cervical and fourth dorsal nerves, to which Budge relegated the origin of the pupil-dilating fibers of the sympathetic, its existence has not been definitely proven.

4. Although the nature of the ciliary ganglion has not been positively determined in any one species of animal, and, although it differs greatly in different species, the weight of evidence is in favor of the ganglion belonging to the sympathetic system, at least in so far as man is concerned. The root fibers which belong to the oculomotor end in the ciliary ganglion, where a new neuron begins for the fibers which pass to the ciliary muscle and the sphincter of the pupil, i. e., the oculomotor does not act directly on the sphincter of the pupil, but only in association with the ciliary ganglion. There is a certain amount of evidence that this ganglion is related to the pupil movements in the form of a center, and it probably contains cells which are active in the sensibility of the cornea, but lesions of the ganglion itself, although they have been considered by Grosz to be the basal cause of true neuroparalytic keratitis, have not been proved to sustain this position by experiments, inasmuch as trophic changes have not been observed after extirpation of the ganglion. Removal of the ganglion has little or no *influence on intraocular* tension, and its excision is not a rational procedure for the relief of glaucoma.

5. There is *no* satisfying evidence that the sympathetic is related to the function of accommodation, and it has not been proved that the *sympathetic* has any power in causing negative accommodation, nor has it been demonstrated that alterations in refraction noted after stimulation of the sympathetic are due to actual change in the lens.

6. Electrical stimulation of the cervical sympathetic produces at first an increase and later a decrease of intraocular tension, the increase being probably due to an effect on the vessels of the eye. *Slow-acting*, mechanically produced irritation of the sympathetic causes a rise of tension, which, according to Lodato, is independent of dilatation or constriction of the blood vessels, and also independent of the state of the pupil. Section of the sympathetic, or extirpation of the *sympathetic* ganglion, is followed by a fall of intraocular tension, which probably depends on vascular and, perhaps, muscular changes. The lowering of tension is more decided after excision of the ganglion than after section of the sympathetic cords, but in either case the effect is a temporary one, and may not last more than a few days, and sometimes disappears within a few hours.

7. Electrical stimulation of the cervical sympathetic produces on the side stimulated a dilatation of the pupil as a result of contraction of the dilatator pupillæ, associated, perhaps, with an inhibition of the sphincter. At the same time there may occur on the opposite side a contraction of the pupil, which either depends on the consensual pupil reflex, or represents a reflex transmitted through the sympathetic fibers joining the cranial nerves in the region of the cavernous sinus.

8. Electrical stimulation of the cervical sympathetic causes retraction of the nictitating membrane and proptosis, owing to the action transmitted to the unstriped muscular fiber. In contrast to the general rule, irritation of the sympathetic in rabbits causes a retraction of the eyeball in the orbit, which has been attributed by Heese to a contraction of the orbital vessels and the anemia which this causes.

9. Electrical stimulation of the cervical sympathetic *is followed by contraction of the blood vessels of the* conjunctiva and of the iris, and perhaps by alteration in the caliber of the vessels of the retina, although observations on the last-named phenomenon have been extremely contradictory.

10. Stimulation of certain areas of the brain cortex causes dilatation of the pupil, associated, if the cervical sympathetics are intact, with all the symptoms of stimulation of the cervical sympathetic. Division of the sympathetic stops the other symptoms, but not the dilatation of the pupil, which is supposed to be due to inhibition of the tonic action of the third nerve (Parsons).

11. Sympathectomy or gangliectomy causes the following effects: Myosis, narrowing of the palpebral aperture, projection of the nictitating membrane, retraction of the globe of the eye, hyperemia of the vessels of the conjunctiva, increased lachrymal secretion, diminished intraocular tension, certain ophthalmoscopic and microscopic lesions in the eyeground, and possibly trophic disturbances.

12. *The symptoms of sympathetic section or paralysis* lessen after a time, myosis being the most permanent, lasting sometimes for years. The degree of permanence, however, of the paralytic phenomena varies much in different animals.

13. Myosis is greater after excision of the cervical sympathetic ganglion than after section of the sympathetic cord, because it is probable that a certain tone is exercised by the ganglion; that is, that it has a different, and, as it was, a stronger action on the eye than the nerve trunk itself (Levinsohn).

14. All the phenomena of paralysis of the sympathetic nerve, especially the contraction of the pupil, which follow extirpation of the superior cervical gang-

---

* Author's abstract of a paper read at the Fifty-Fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John F. Weeks, and published in full in the Transactions of the Section. Only the conclusions of the paper are here given.

lion gradually become less marked and may disappear or even give place to the opposite condition, especially if the animal is anesthetized or subjected to sensory or emotional stimuli. In other words, extirpation of the upper cervical ganglion causes the symptoms of sympathetic paralysis which may disappear and give place to the signs of sympathetic excitation. Such paradoxical pupillary dilatation may depend on degenerative processes in the post-cellular nerves of the ganglion (Langendorff).

15. The myotic pupil, which follows sympathectomy or gangliectomy, responds to light stimulus, is still further contracted by eserin, and may be dilated by atropin. It is uninfluenced by cocain, which, however, may exercise its influence in widening the contracted palpebral fissure.

16. A considerable excision of the sympathetic must be made in order to prevent a rapid regeneration.

17. Narrowing of the palpebral fissure, ptosis sympathica, and enophthalmos are probably due to relaxation of Müller's muscle, aided, perhaps, by atrophy of the orbital fat. It has not been proved, although it has been asserted, that there is an actual reduction in the size of the globe, that is, a true microphthalmos, under these circumstances.

18. Sympathectomy or gangliectomy may cause increased vascularization of the eyeground, perhaps hemorrhages in the ciliary body and ciliary processes, and alteration in the retinal ganglion cells.

19. Puncture of the restiform body produces just the opposite effects of destruction of the sympathetic (Dupuy).

20. Nicotin paralyzes the activity of ganglionic nerve cells in the sympathetic. Cocain dilates the pupil by stimulating the mydriatic nerve endings in the iris. Atropin dilates the pupil, partly by a paralytic action on the oculomotor endings of the sphincter, and, perhaps, by a stimulant action on the sympathetic nerve fibers, or more likely, by causing a general paralysis of the unstriped pupillary muscle. Instillations of adrenalin, ordinarily inactive in causing dilatation of the pupil, become exceedingly active when the sympathetic is cut or the ganglion removed, and cause under these circumstances marked dilatation of the pupil.

---

# INFLUENCE OF RESECTION OF THE CERVICAL SYMPATHETIC

## IN OPTIC-NERVE ATROPHY, HYDROPHTHALMOS AND EXOPHTHALMIC GOITER.[*]

JAMES MOORES BALL, M.D.
Professor of Ophthalmology in the St. Louis College of Physicians and Surgeons.
ST. LOUIS.

### I. SYMPATHETICECTOMY IN OPTIC-NERVE ATROPHY.

*History.*—Excision of the cervical portion of the sympathetic nerve for the relief of optic-nerve atrophy was proposed and executed by the writer in 1899. (The date of the first operation was June 24.)

*Report of Cases.*—A report of this case was included in a paper[1] which was read before the Ninth International Ophthalmologic Congress, in 1899. From that paper I now quote:

T. J., aged 46, an inmate of the St. Louis City Hospital, a laborer, was admitted on account of blindness. There was no history of syphilis, rheumatism nor any systemic disease. The patient was of limited mentality. No history of his family could be obtained. He claimed to have had good health all his life, with the exception of an attack of malarial fever several years ago. The patient has been a moderate drinker of alcoholic beverages. In appearance he was robust, and he complained only of loss of vision, which in the left eye had been failing for eleven months, in the right for seventeen weeks according to his statement. Until seventeen weeks before this time he could see enough with the right eye to get around. Since then vision had steadily declined until he had light perception only—and this apparent only when light was concentrated on the eye by the ophthalmoscopic mirror. Vision of left eye =0.

The pupils were widely dilated. The ophthalmoscope showed in the right eye a white disc, particularly on the temporal side; the arteries were slightly reduced in caliber, veins normal. There was shallow, atrophic cupping of the nerve-head. The retina and choroid were normal, the vitreous and lens clear. The left eye showed a disc of a dead white color throughout the whole area, arteries very small, atrophic excavation pronounced, veins reduced in caliber and choroid normal. The macula was not visible in this eye, owing to the much reduced blood supply. The vitreous and lens were clear. Vision was as follows: R. E. = perception of concentrated light. L. E. =0.

*Diagnosis.*—R. E.= optic nerve atrophy. L. E. = complete atrophy of optic nerve and retina.

*Treatment.*—Resection of the right superior cervical ganglion of the sympathetic was done. The operation was followed by conjunctival congestion, lachrymation and contraction of the pupil, slight ptosis and hypotonia.

No appreciable change in the patient's vision followed, and ophthalmoscopic examination made two weeks after operation showed no change in the appearance of the fundus, except that a cilioretinal artery in the upper part of the disc had doubled in caliber.

I was led to make this experimental operation for several reasons: 1. The use of glonoin is often followed by an improvement in vision in cases of simple atrophy of the optic nerve. 2. Glonoin enlarges the retinal vessels, as has been proved by ophthalmoscopic examination. 3. There is no question that in glaucoma simplex—a disease in which there is an atrophy of the optic nerve—improvement in vision follows sympatheticectomy. 4. Excision of the cervical sympathetic is followed by an increase in the blood supply of the orbital contents.

My second case of sympatheticectomy for optic nerve atrophy occurred in the summer of 1900. It has not been reported, for the reason that an assistant lost the case history. The result, however, was all that could be expected.

The patient was an Irishman, a bartender by occupation. He was about 40 years of age. For several months the vision of both eyes had steadily declined. Several oculists had given him medical treatment for simple optic-nerve atrophy without result. The poorer eye had vision equal to the counting of fingers at two feet. I excised the superior cervical ganglion of the sympathetic nerve on the corresponding side. Vision steadily increased to 20/100. The patient was lost sight of, but one year later he sent word that his vision was excellent and that he was following his vocation.

I regret that this case can not be more fully described. My third case of atrophy treated by sympatheticectomy occurred in 1901.

J. H., aged 64 years, a native of New York City, for 18 years had been a sailor. For many years he was excessively addicted to the use of alcohol and tobacco. In 1888 he contracted syphilis, for which he was treated for two months. Vision in R. E. began to fail in 1898; in L. E. in 1900. He was admitted to the St. Louis City Hospital on Jan. 29, 1901. The hospital record shows that he was in good general health. He was given large doses of mercury and iodids.

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

1. Ball: On Removal of the Cervical Sympathetic in Certain Ocular Diseases—Glaucoma and Optic Nerve Atrophy, Neuvième Congrès International d'Ophtalmologie d'Utrecht, 1899, p. 551.

Patient came under my care on March 1, 1901. His general condition was good. Vision of R. E. =0; of L. E. = fingers at 6 inches. The ophthalmoscope showed a *typical* picture of simple atrophy of the optic nerves. Strychnia in increasing doses was ordered and was continued for five weeks without benefit.

On April 11, 1901, assisted by Dr. R. F. Amyx, I excised the left superior cervical ganglion of the sympathetic nerve. At this time the right eye was absolutely blind; with the left eye fingers could be counted at 6 inches. Two days after the operation he counted fingers at 15 feet. On April 27 he counted fingers at 12 feet. There was a gradual loss of vision, until at the end of a few weeks the patient was in the same condition as before operation.

*Cases Reported by Other Surgeons.*—Suker[2] performed a bilateral sympatheticectomy in a case of bilateral simple atrophy of the optic nerve. Before operation the visual acuity was reduced to form perception at two feet. After operation the hand could be recognized at six feet. Two years later the acuity was retained.

Renaud[3] has reported one of my cases and two of his own. In January, 1900, he made a bilateral sympatheticectomy for a unilateral optic-nerve atrophy which followed an attack of optic neuritis existing four months previously. Vision was reduced to the counting of fingers at six feet. Four and one-half months later the patient could count fingers at eighteen feet (V.= 20/100). Renaud's other case, which was one of simple atrophy, showed in two months an improvement in vision from 10/200 to 20/50. Renaud[4] has operated on another case without success.

E. Gruening[5] of New York has had one case which is best described in his own words:

> My experience with the excision of the superior cervical sympathetic ganglion in atrophy of the optic nerve is limited to one case. It concerned a man, 33 years of age, who had contracted syphilis fifteen years previously. When I saw him in 1902 he was entirely blind as regards his left eye, but saw well centrally with his right. Here the field was telescopic, measuring ten degrees in diameter. Vision was 20/30. He read J. 1. Pupils small. Argyll-Robertson reaction—knee reflexes lost entirely—a case of post-syphilitic tabes with atrophy of the nerves. The ganglion was removed on the right side. Vision became worse and three months later the man was totally blind.

Thus, of 8 cases in which sympatheticectomy was performed by optic-nerve atrophy, there were 4 failures and 4 improvements.

*Should Bilateral Resection be Done for Unilateral Atrophy?*—At the present time it is impossible to answer this question *ex cathedra.* Renaud states that "the superior cervical ganglion should be removed on both sides in all cases, whether the affection be unilateral or bilateral." It is possible that the unexcised ganglion exerts an influence on the opposite eye, the anatomic path probably being through anastomosis of fibers in the carotid plexus.

### II. TREATMENT OF HYDROPHTHALMOS BY OPERATIONS ON THE SYMPATHETIC NERVE.

Few cases of congenital hydrophthalmos have been treated by operations made on the cervical sympathetic. Palmtag and Nolle removed the superior ganglion, while Schwilke and Mader performed sympatheticotomy. These four patients were 8, 2½, 4½ and 9 years of age, respectively. The tension was uninfluenced, and the vision, so far as could be determined in such young subjects, was unchanged. The operations, consequently, were valueless. Grunert[6] states that the general health of these children was not influenced by these procedures.

### III. OPERATIONS ON THE SYMPATHETIC NERVE FOR THE RELIEF OF EXOPHTHALMIC GOITER.

Exophthalmic goiter is a disease belonging to the domains of the ophthalmologist, neurologist, surgeon and general practitioner.

Without desiring to enter into a résumé of the literature of the last ten years or to excite a discussion on the nature of the disease, I will remark that there are good reasons for dividing cases of exophthalmic goiter into three groups, as advocated by Lanphear:[7]

1. Those dependent on changes in the central nervous system, in which no operative measures can be of benefit.

2. Those due to disease of the cervical sympathetic, in which excision of the ganglia may give relief.

3. Those arising from excessive thyroid secretion, in which thyroidectomy may cure.

Granting that a certain percentage of cases will recover spontaneously; that some will show great improvement without treatment; that others will recover under the rest cure, or by change of climate, or by the influence of pregnancy; and that some will recover under the use of such diverse measures as cauterization of hypertrophied inferior turbinated bodies, the removal of nasal polypi, the painting of the thyroid region with collodion, the use of the galvanic current, or of the faradic current the administration of iron, quinin, belladonna, digitalis, strophanthus, hydroiodic acid, ergot, spartein, salicylate of soda, corbolozate of ammonia, thyroid extract, etc., there will still remain a not inconsiderable number of cases in which surgical intervention will be required.

Before resorting to any form of operation it is well to remember (1) that no surgical procedure will cure all cases, and (2) that sudden death has not infrequently followed carefully planned and skilfully executed operations made on this class of patients. Harris[8] has reported the death of a lady who, having exophthalmic goiter, was operated on for the removal of a non-malignant mammary tumor and died suddenly. Lancereaux[9] has called attention to the danger of sudden death after goiter operations, and has commented on the great value of morphin in such patients. Warren[10] has advanced the idea that during the operation a toxic substance from the thyroid may gain admission to the circulation and cause death. Booth[11] states that, owing to the care which is now exercised in the removal of the diseased gland, this theory is no longer tenable.

Patients with simple goiter often do badly under general anesthetics. In addition to the dangers pertaining to such cases, the patients with exophthalmic goiter must face other dangers. The chance of death from chloroform, according to Halstead,[12] is much increased by the degenerated heart muscle and the increased irritability of the heart centers; and in the retrosternal and retroclavicular forms of goiter ether anesthesia is equally dangerous. Fütterer has shown that collapse of the trachea, which may occur after operation for any form of goiter, is due to mucoid degeneration of the cartilaginous tracheal rings. The patient makes a violent inspiratory effort, collapse of the trachea results and death occurs by asphyxia. Because of these dangers, not a few surgeons, including Kocher,[13] believe that goiter operations should be performed under local anesthesia.

### CLASSIFICATION OF OPERATIONS ON THE CERVICAL PORTION OF THE SYMPATHETIC NERVE.

These procedures, which have been tried in the treatment of exophthalmic goiter, are:

1. Simple division of the cervical sympathetic (first suggested by Edmunds[14] in cases in which perforation of the cornea is threatened, and first performed by Jaboulay).
2. Ablation of the cervical sympathetic, consisting in the torsion and ablation of the nerve by means of artery forceps passed through a small incision (Jaboulay's procedure).
3. Simple stretching of the cervical sympathetic (first practiced by Jaboulay).
4. Partial resection of the cervical sympathetic (first performed by Alexander of Edinburgh, in 1889, for the cure of epilepsy, and limited by him to the removal of the superior ganglion).
5. Partial and extensive resection (excision of the upper and middle ganglia with the intervening strand).
6. Total resection of the cervical sympathetic (removal of all three ganglia and the nerve strand). This was first performed by Jonnesco.
7. Thyroidectomy with partial and extensive resection of the cervical sympathetic, was suggested by the writer in 1901, in a case under the care of Dr. F. Robert Boyd, and was practiced by Dr. J. W. Smith of St. Louis.

The comparative value and mortality of exophthalmic goiter operations can not be definitely determined, because (1) many cases ending in death have not been reported, and (2) not all of the published statistics are reliable, there being in some of the published reports an absence of differentiation between the various procedures practiced on the sympathetic nerve.

1. *Thyroidectomy.*—The general mortality of this operation is 7 per cent. (Booth[15]), while the percentage of death in cases of exophthalmic goiter is much higher. Rehn[16] of Frankfurt, who collected 177 cases, places it at 13.6 per cent. Tricomini[17] (72 cases) places the mortality at 15 per cent., and Sorgo[18] (172 cases) at 14 per cent. Jonnesco[19] claims that the mortality is over 17 per cent., and rejects the operation because of the high death rate. Kocher's[20] recent statistics are very favorable. He made 59 operations: 45 cases (76 per cent.) were cured; 8 (14 per cent.) were improved; 2 (3.3 per cent.) were slightly improved, and 4 (6.7 per cent.) died. When we remember that many of the unsuccessful cases have not been reported, it seems reasonable tó place the mortality of thyroidectomy for exophthalmic goiter at 20 per cent. Rehn[21] claims 57.6 per cent. of cures for thyroidectomy. Jonnesco claims that the reported successes of this operation have been largely among those atypical cases in which the goiter long preceded the ocular and cardiac symptoms. Doyon is a strong advocate of thyroidectomy, and would resect the sympathetic only after failure of the former operation.

The danger of sudden death after thyroidectomy is emphasized by Starr's report. Of 190 cases, not less than 23 died suddenly. Surrel,[22] who has recently discussed this subject, attributes these accidents to either an acute thyroidin intoxication, or to a sudden stoppage of the heart's action. The latter is supposed to be caused by the traction which, during the operation, is exerted on the nerves of the thyroid gland, which are intimately associated with the vagus nerve.[23] After thyroidectomy a number of complications have been observed, such as a rise of temperature, which is accompanied by a sensation of heaviness, dyspnea, tachycardia and vomiting. Hemorrhages, tetany and vocal disturbances, dysphagia and bronchopneumonia have also been observed.

2. *Ligation of the thyroid arteries,* according to Rehn,[24] gives a mortality of 28.6 per cent.; 2.4 per cent. were cured, and 50 per cent. were improved. Regarding this, Balacescu[25] says: "The method of ligaturing the thyroid arteries has been the first to be abandoned (among operations attacking the thyroid gland), because in nearly all cases the disease recurred in a few months after operation. Secondly, the execution of this operation was difficult where the thyroid was very large, especially in cases in which its relations to surrounding tissues were altered; or it predisposed to secondary hemorrhages on account of the fragility of the vessels." Kocher, Kopp and Rehn have recorded cases in which this operation was followed by tetany.

3. *Exothyropexy,* which was first done by Poncet and Jaboulay, consists in exposing the thyroid gland, and suturing it in the wound, where it is left exposed, in the hope that atrophy will occur. This operation has been abandoned by Poncet, because of the high mortality (23 per cent.) and the frequent recurrence of Basedow's disease after this procedure.

*Simple Section of the Sympathetic Nerve.*—Jaboulay[26] performed bilateral section in 6 cases and the unilateral operation in 2 cases. He records 2 cures, 5 improved cases and 1 death, which occurred 18 months after operation—a mortality of 12.5 per cent. In all of these patients the exophthalmos was influenced favorably after the first day; the thyroid enlargement disappeared slowly, while the tachycardia was scarcely influenced by the operation. He proposes that in cases in which the tachycardia is pronounced the inferior cervical ganglion shall be excised. Balacescu[27] claims that simple section influences the exophthalmos and thyroid enlargement but little, and the tachycardia not at all. Pean[28] pronounces the operation resultless and unnecessary. He advocates thyroidectomy. Gayet[29] has stated that simple section powerfully influences the triad of symptoms, and this effect is permanent. It must be remembered that Gayet's article appeared in 1896, while that of Balacescu was published in 1902.

5. *Stretching of the Cervical Sympathetic.*—In the only (Jaboulay's) case in which this operation was performed the tachycardia was markedly increased, the pulse ranging from 110 to 130 two weeks after the operation. The exophthalmos and thyroid enlargement were uninfluenced.

6. *Stretching of the pneumogastric nerve* has been tried by Jaboulay[30] in cases of exophthalmic goiter with severe cough. It is said to arrest the laryngeal spasms. This procedure must be regarded as dangerous and without curative value.

7. *Ablation of the cervical sympathetic* has been abandoned.

8. *Partial Resection* (Removal of the Superior Ganglion) *and Partial and Extensive Resection* (Removal of the Superior and Middle Ganglia with the Intervening Strand).—These procedures have gained an established position among exophthalmic goiter operations. Balacesu[31] reports 27 cases which were treated by partial resection, and were observed for periods varying from 1 to 4 years. In all of these cases there was rapid and pronounced improvement. The exophthalmos disappeared within the first few days, the thyroid diminished in the first 8 days, but the tachycardia persisted, the pulse ranging from 110 to 120. The palpitation did not return, and the facial expression was much changed for the better. After a time, the tachycardia showed a tendency to decrease, but never was as pronouncedly influenced as were the other Basedow symptoms. In this series of 27 cases there were 9 cures, 11 improvements, 2 uncured cases and 5 deaths, none of which could be attributed to the operation. The mortality of these procedures is small, probably less than 5 per cent. Sudden death, however, has occurred after partial resection. One such case, which was operated bilaterally by Bernays and Simpson[32] of St. Louis, died of heart failure on the 11th day. That partial resection is not always curative is shown by a case recorded by Chauffard and Quénu,[33] who removed the superior ganglia without influencing the exophthalmos and goiter. It seems reasonable to concede (1) that partial resection is the operation of choice in those cases of exophthalmic goiter in which the ocular and thyroid are more prominent than the cardiac symptoms; (2) that the bilateral resection should be made, but not at the same sitting, an interval of 2 or 3 weeks being advisable; (3) that the mortality is low.

9. *Total bilateral resection* is the procedure of choice among the sympathetic operations. Of 19 cases which are reported by Balacescu[34] as occurring in the practice of Jonnesco, Soulié, Faure, Peugnecz and Dépage,[35] in 14, after the second day after operation, the Basedow symptoms disappeared one after another. This improvement continued daily until cure was complete. This report is verified by the experience of Halstead[36] and Witherspoon.[37] Halstead, writing four weeks after total bilateral resection, says: "The patient's exophthalmos has greatly improved; the pulse is better, the tremor and general nervous condition are improved." Witherspoon, in 1899, was consulted by a woman aged 59 years, who showed moderate exophthalmos, marked enlargement of the right thyroid lobe, and a pulse rate varying from 130 to 150. She heard strange noises and had ideas of persecution; the skin was moist, and the urine showed casts and albumin. The diagnosis was chronic interstitial nephritis, associated with Graves' disease. Believing that in her general condition thyroidectomy was contraindicated, Witherspoon advised sympatheticectomy. On September 10 the operation was made on the right side. Eleven days later the left side was operated on. After the second operation the pulse showed improvement in quality and rate, the exophthalmos and enlargement of the thyroid almost completely disappeared, and her mental condition improved. In December she went on a visit to the country. In the following February, while riding, she became chilled and died two hours afterward. Up to the present time no deaths have been directly attributed to the total excision of the cervical sympathetic. The results are 63.8 per cent. of cures; 18.1 per cent. of improvements; 18.1 per cent. of failures, and no deaths.

10. *Thyroidectomy with partial resection of the cervical sympathetic* was performed on a patient of Dr. F. Robert Boyd by Dr. J. W. Smith and myself. The patient nearly died on the table from hemorrhage following the slipping of a ligature. She expired suddenly on the third day. The temperature rose suddenly and the pulse became too frequent to be counted.

The failure of thyroidectomy to relieve the exophthalmos of Basedow's disease was remarked on by Stevenson and Shears.[38] In the case of a woman, aged 25 years, from whom the right lobe of the thyroid had been removed 4 years previously, while the general symptoms were improved greatly, the exophthalmos had steadily increased. It is possible that cases presenting marked exophthalmos and thyroid enlargement without much tachycardia may be cured by thyroidectomy, combined with resection of the superior cervical ganglion.

### CONCLUSIONS.

1. Excision of the superior cervical ganglion of the sympathetic nerve is worthy of a trial in those cases of simple atrophy of the optic nerve which resist measures less heroic.

2. It is yet impossible to say whether the bilateral operation is advisable in unilateral optic-nerve atrophy.

3. The value of sympatheticectomy in congenital hydrophthalmos has not been demonstrated.

4. In exophthalmic goiter, complete excision of the cervical sympathetic is followed by a larger percentage of cures than is any other procedure. Thus far no deaths have been recorded. The number of operations, however, is small and final conclusions can be announced only after a large number of cases shall have been treated by this method.

**International Anti-Rat Society.**—Some years ago an international association was founded "to disseminate an idea as to the ravages caused by rats." An international exhibition of apparatus for the extermination of rats was held at Copenhagen in 1901, but at that time the rat did not have the same interest from a medical point of view that he now possesses. The permanent secretary is Prof. Peter Oesterby, 16 H. C. Orstedvej, Copenhagen, Denmark. A bounty of a penny per rat has been found to accomplish wonders in Denmark and in England. In London alone over 180,000 rats have been killed on the wharves.

# PATHOLOGY OF THE CERVICAL SYMPATHETIC.[*]

JOHN E. WEEKS, M.D.
NEW YORK.

The departure from the normal in the cervical sympathetic may be classed under two heads, namely, irritation and paralysis.

1. The symptoms of irritation are: (a) mydriasis, due to spasm of the dilator pupillæ; (b) exophthalmus, said to be due to contraction of the smooth muscular fibers of the orbit (Müller's); (c) widening of the palpebral fissure by tonic contraction of Müller's muscle; (d) contraction of the walls of the vessels of the head, face and neck, including pallor of the skin, frequently with an increase in the amount of perspiration; (e) acceleration of the heart beat.

According to Nicati,[1] paralysis of the cervical sympathetic may be divided into two stages:

*First Stage.*—(a) Contraction of the pupil, (b) narrowing of the palpebral fissure (ptosis), (c) decrease of the tension of the globe, (d) increased lachrymation, (e) injection of the ocular conjunctiva, and, in many cases, (f) slight exophthalmus. There is also congestion of the corresponding side of the face, anidrosis in the greater number of cases, sometimes hyperidrosis; also acceleration of the heart action in a minority of the cases.

*Second Stage.*—The ptosis remains. The miosis persists for some months. The miosis, consequent on removing the stellate ganglion in animals, is recovered from in two to three months.[2] The tension of the eyeball becomes normal after some weeks or months, gradually becoming less pronounced. What may be termed the vasomotor disturbances disappear in a relatively short time. In exceptional cases, atrophy of the tissues of the corresponding side of the face follows.

Cases of irritation of the cervical sympathetic are not common. They have been observed as being due to abscess in the neck;[3] pressure of tumors, as malignant growths, cystic goiter,[4] with exophthalmus; thoracic aneurism;[5] injuries to the neck;[6] injuries to the spinal cord, between the fifth cervical and third dorsal vertebræ.[7]

Irritation symptoms may pass over to symptoms of paralysis and again return to those of irritation, due to irregular pressure. Cystic growths are most apt to produce these phenomena. In consulting the literature on affections of the cervical sympathetic, the writer has studied the reported cases of irritation of this portion of the sympathetic nervous system for the purpose of ascertaining if any of the patients suffered from glaucoma. Quite a full list of the reported cases of this nature is given by Lloyd.[8] In none of the histories of such cases is mention made of glaucoma as a complication.

Paralysis of the cervical sympathetic may be due to the pressure of tumors, glandular swellings,[9] malignant neoplasms,[10] cicatrices in the neck, aneurism,[11] abscess,[12] wounds of the neck,[13] injuries to the brachial plexus involving the sympathetic, diseases and injuries affecting the spinal cord, spinal caries, various pulmonary affections; paralysis of the cervical sympathetic also apparently occurs idiopathically.

Tumors originating in the sympathetic and interfering with its function are extremely rare. A case of fibrosarcoma of the cervical sympathetic is reported by Abbe,[14] and he refers to cases reported by Paget, Prudden, Virchow, Satterthwaite and Reynolds of neurofibromata affecting the sympathetic.

Of the symptoms said to be due to abnormal conditions of the cervical sympathetic and the consequent influence on the vessels, migraine may be mentioned. This may be preceded or accompanied by disturbances of vision, (a) periodic hemianopsia, (b) scintillating scotoma, (c) monolateral transient amaurosis, and (d) monolateral photophobia. Accompanying migraine we may also have flushing of one side of the face, anidrosis or hyperidrosis, with narrowing of the palpebral fissures and moderate miosis.

The affections of the eye, supposed to be caused in greater part by abnormal conditions of the cervical sympathetic, are glaucoma and exophthalmic goiter. It is not the province of this article to enter into a discussion of the relation of the cervical sympathetic to these diseases further than to inquire into the changes, if any, that have been observed in the tissues of the cervical sympathetic occurring in individuals affected by these diseases.

## THE GANGLIA OF THE CERVICAL SYMPATHETIC.

The ganglia are surrounded by a thin, firm, adherent covering of connective tissue which sends prolongations into the ganglia, dividing them into compartments of various sizes and serving as a supporting structure. A delicate capsule, composed of a single layer of cells bearing nuclei, surrounds each ganglion cell. The ganglion cells have an average diameter of 20 microns, but vary from 13 to 40 microns. The ganglion cells possess one to three processes, one of which is an axon. The cells are made up of a protoplasmic body containing a nucleus and nucleolus. Many of the cells contain a greater or less number of pigment granules. The ganglia contain numerous nerve fibers, only a few of which are medullated. The blood vessels are small and not numerous.

The nerve-trunk resembles the ganglia, except that it contains no ganglion cells, and apparently contains a greater proportion of medullated nerve-fibers.

## PATHOLOGIC CHANGES.

The writer has little doubt that the ganglia of the cervical sympathetic in the aged undergo degenerative changes to some degree. It is certain that these ganglia as examined in the dead-house vary much in size and appearance.

Hale White found in examining 33 semilunar ganglia, taken from persons dying from different causes, that most of them showed degenerative changes (Onuf and Collins).

Gustav Ricke[15] reports a case presenting symptoms of irritation of the cervical sympathetic. Autopsy showed round-cell infiltration and small hemorrhages in the superior cervical ganglion of the affected side. He thinks that paralysis of the vasomotor fibers and irritation of the oculopupillary fibers occurred.

Petrow[16] describes changes occurring in the sympathetic in constitutional syphilis. In twelve cases which he examined he found distinct alterations in the nerve elements and in the interstitial connective tissue, hyperplasia of the latter being apparent. There was pigment and colloid degeneration in the nerve-cells, alterations in the cells of the sheaths of the ganglion cells consisting of increase in size and proliferation. The endothelial cells showed secondary fatty degeneration.

Pio Foa (*Sull' anatomia del gran simpatico*) wrote concerning some changes he had observed in the sympathetic in various diseases. These were found chiefly in the cervical and abdominal ganglia, and consisted sometimes of simple or fibrous atrophy, at other times of hyperemia, sclerosis, pigmentary and fatty infiltration, amyloid degeneration, accumulation of colorless blood-corpuscles and the presence of micrococci in the blood vessels of the ganglia. These alterations are well marked in syphilis, leukemia, pellagra, tuberculosis and infectious diseases.

Mention should be made of two reports by Koster[17] on the state of the cervical sympathetic in persons who had died suddenly from sunstroke. In one case, that of a soldier, the superior ganglion of the right sympathetic was twice the size of the left and was the seat of hemorrhagic effusion; microscopically, the nerve-fibers were seen to be separated and disintegrated. There were small hemorrhages in the upper part of the right sympathetic, while slight effusions of blood were found in and around both vagi and in the sheaths of both phrenic nerves. In the second case, that of a woman 21 years of age, the pathologic phenomena were a hemorrhagic infiltration and enlargement of both superior ganglia of the cervical sympathetic, while the microscope revealed the same appearances as in the other case: there were also ecchymoses as large as peas in both vagi. In the first case, the patient had lived twenty-four hours, having a pulse so rapid that its beats could scarcely be counted; there was, however, no acceleration of the respiration.

### GLAUCOMA.

The ganglia excised in Ball's cases were examined by Dr. Carl Fisch[18] of St. Louis. A great number of different staining methods were employed, but those of Golgi, Marchi and Nissl were not employed, on account of the method of hardening the specimen. The changes found were approximately the same in all cases.

The most striking change was "a very marked hyperplasia of the connective tissue, which, in some places, resulted in dividing up the ganglion into small groups of nervous elements, separated by broad bands of fibrous elements." There was decided sclerosis of the walls of the vessels and the capsules of the ganglion cells were "much increased in thickness." "In Case 1, small foci of round-cell infiltration are seen in this hyperplastic growth of an inflammatory character." No "plasma or mast-cells" could be demonstrated.

The ganglion cells were "immensely" pigmented; many were in various stages of degeneration. Only a few showed normal dendritiform processes. The network of processes was reduced in volume and compressed by the connective tissue new formation. The general aspect was that of a general sclerosis, inflammatory and originating in the walls of the vascular structures. The changes in the nervous elements are attributed to pressure and inhibited nutrition.

Ziehe and Axenfeld (*Sympathicus-Resection beim Glaucoma,* Halle, 1901) report the examination of five ganglia removed from three patients at Rostock. The ganglia were examined by Dr. Recker, Privatdocent, working in the Pathologic Institute at Rostock.

Case 1.—Capsule thick; the connective tissue that accompanied the blood vessels was also thickened. Connective tissue poor in nuclei. Often the adventitia was thicker than the remaining portion of the wall of the vessel, plus the lumen of the vessel. A slight increase in the small cells was observed in the vicinity of the vessels. No change in nerve elements. Both ganglia presented the same microscopic appearance.

Case 2.—Right ganglion; marked diffuse interstitial sclerosis, most pronounced in the vicinity of the larger blood vessels. Nerve elements normal. The left ganglion showed the same changes, but to a less degree. Leucocytes slightly increased in number.

Case 3.—The left ganglion, which was the only one removed, showed increase of the connective tissue about the blood vessels; adventitia very much thickened. Diffuse interstitial sclerosis absent.

Lodato[19] examined two ganglia removed from a patient with glaucoma and found hyperplasia and sclerosis of the connective tissue and a peripheral small-cell infiltration. The sclerosis was more marked in the ganglion from the older patient, the small-cell infiltration in the ganglion from the younger patient.

In the first he found a number of small hemorrhages which had destroyed some of the nervous elements. There was some degeneration of a few of the medullated nerve-fibers. No change in the nerve-elements in the second case.

Lodato questions whether the small-cell infiltration might not have produced an irritation which could have caused a hypersecretion of fluids into the globe, and thus have established the first stage of the glaucoma. There is no report of control examinations.

Albertotti[20] gives an example of ten superior cervical sympathetic ganglia, the cut being reproduced from a photograph, which shows them to be of various sizes and shapes.

Cutler[21] reports, regarding the microscopic examination of one superior cervical ganglion removed from a patient suffering from glaucoma simplex, as follows:

> Specimen 5 centimeters long, ½ centimeter in diameter. At one point for 1½ centimeters is a thickening. Sections through whole length of specimen show large ganglion cells In these cells the chromophilic bodies do not show the normal size and arrangement, and many cells show small granules of pigment. A growth of connective tissue is between the ganglion cells. Nerve fibers are normal.

When we take into consideration the fact that degenerative changes in the cervical sympathetic occur in the old, whether there is marked evidence of disease or not, it becomes apparent that it is necessary to make control examinations before we can reach any reliable definite conclusion regarding the condition of the cervical sympathetic in individuals suffering from glaucoma, or, in fact, in any disease supposed to be due to pathologic changes in the cervical sympathetic. Such control experiments were made by Dr. Ira Van Giesen, in connection with the examination of the ganglia removed, in the cases reported by the writer.[22] His report follows:

---

[20] Ann. di ottalm., Naples, xxix, p. 472.
[21] Annals of Surgery, Phila., September, 1902.
[22] Trans. Amer. Ophth. Soc., 1902, p. 455.

Seven ganglia have been examined microscopically, including two bilateral operations, comprising thus five different cases. The work has been paralleled by the examination of control ganglia taken from subjects as near as possible the same age as the operation cases. As the control studies are very important in an examination of this kind, the normal ganglia were subjected to precisely the same steps as in the operation cases, and carried along with them side by side. Four ganglia of normal subjects were studied as controls and secured in autopsies averaging about twenty-four hours after death. (Thus far, however, but two of the control ganglia have been complete for study.)

We have endeavored to bring to bear on the question as comprehensive an examination as possible, and the technic has been directed toward all of the structures of the ganglion in the following order: (1) The detection of any cytologic changes in the neuron cell bodies. (2) A special study of the so-called pigment granules in the neuron cell bodies. (3) An examination of the connective tissue framework of the ganglion. (4) A study of the blood vessels; and (5) the examination of the medullated and non-medullated fibers.

Special methods, both of fixation and staining, have been used for each of these points in both sets of ganglia—the operation cases and the control cases—and in all some three hundred sections have been examined. Ten different fixations have been employed, as well as the several varieties of staining methods best adapted for the demonstration of each of the objects of examination.

1. *The Neuron Cell Bodies.*—Throughout the series of operated cases, the neuron cell bodies show the normal arrangement and distribution of the chromophilic granules. There are no evidences of degeneration, nor is there any atrophy or signs of disappearance of the neuron cell bodies. In a very few places, in fact, of quite exceptional occurrence, there are appearances which might be considered as similar to the form of chromatolysis in the centers of the neuron cell bodies seen in the central nervous system. This, however, is also seen in the control cases, and it seems to be of no significance in relation to the production of the glaucoma.

2. *The Pigment Granules.*—The capsules of the ganglion cells are also without alteration. The pigment grains are certainly increased in the glaucoma cases as compared with the control cases. A larger number of cells contain pigment grains in the glaucoma cases, and the aggregate volume of the pigment grains is greater. While the control cases contain a considerable amount of pigment particles, this can be reckoned as being only fifty to sixty per cent. of the quantity in the operation cases.

3. *The Connective Tissue.*—Studied in specimens prepared in Fleming's weak and strong solutions and stained by the picric acid fuschin method, the connective tissue framework shows no signs of proliferation or degeneration in the glaucoma cases. One would not be able to distinguish between the operation cases and the controls, judging by the connective tissue.

4. *The Blood Vessels.*—These were examined with especial attention, both in the substance of the ganglion and in the loose connective tissue surrounding it. The vessels are normal.

5. *The Fibers.*—The medullated fibers in the ganglion are so relatively few as compared with the non-medullated fibers that Weigert's method of staining the medullated sheath leaves the section quite decolorized. There are not enough medullated fibers to take the stain. Under the microscope, however, the bundles of fibers in the ganglion show here and there the darkly-stained medullated fibers among the axons. Compared with the controls there seems to be no differences in the non-medullated fibers.

*Summary.*—We find, then, that as far as our methods of examination of hardened material go the ganglia seem to be normal with the exception of an excess of pigment in the neuron cell bodies, and as to the significance of this, if it has any, we are entirely as yet in the dark. The result of the examination does not positively preclude the existence of a lesion in the ganglia. (The ganglia were examined at the new pathologic laboratory of the Women's Infirmary of New York.)

Dr. W. H. Wilder of Chicago has kindly permitted me to refer to the microscopic findings in the ganglia removed from patients with glaucoma in his service. The examinations were made by Dr. Sidney Kuh, who reports as follows: Excess of pigment in the ganglion cells (age a factor?); cells not round, often appear shrunken; eccentric nuclei, occasionally only the nucleolus visible; cells at times vacuolated; mast cells; vascularity. All of these findings were present in each case except the second finding (that of the cells not being round), as in some of the specimens the cells were perfectly round.

Onuf and Collins[23] write:

> Concerning the morbid findings in cases of Graves' disease, Moebius has recently written: "All sorts of conditions have been described; the ganglia are too large or too small; the nerve too thick or too thin; there is too much connective tissue or too few nerve cells; the nerve cells are deformed, shrunken, or pigmented; there are small hemorrhages, destruction of nerve fibers, etc., etc. To all of which we make an affirmative, choosing to disregard the writer's attempt at irony. We have learned in recent years that in individuals dying of long-standing nervous disease, the so-called functional as well as organic, there are also invariably, especially if the individual be somewhat advanced in years, retrogressive changes in the nervous system. Although Moebius comes to the conclusion that in the majority of cases of Graves' disease nothing characteristic or essential is to be found in the cervical sympathetic to explain the pathogenesis of the disease, it does not seem to us that investigation of the vegetative system of nerves in its peripheral and central distribution has been sufficiently comprehensive to give tenability to his position."

The following report is from the examination of nine ganglia removed from patients suffering from exophthalmic goiter. Five of these patients were in the practice of Dr. B. Farquhar Curtis, who has kindly permitted me to make use of the report. The examinations were made by Dr. F. C. Wood, pathologist to St. Luke's Hospital, to whom I am indebted. I wish to express my thanks to both these gentlemen for their courtesy. This report is of practical value because of the control examinations, which were made in connection with the examination of the ganglia removed from patients suffering from exophthalmic goiter.

1. There is no definite increase in the connective tissue of the ganglia.

2. Pigmentation of the ganglion cells is quite constant and abundant, though not present in all cells.

3. A small proportion, always less than half, of the ganglion cells shows a central chromatolysis when stained by Nissl's method. In some cells the change was advanced and no chromophilic bodies could be seen; in others they were clustered about the periphery of the cell. The nuclei were often eccentric in the degenerated cells.

4. No fiber degeneration could be demonstrated. All the ganglia showed about the same changes.

Control ganglia from autopsy cases dying from a variety of diseases did not show marked chromatolysis, though an occasional cell with degeneration could be seen. The amount of pigment formed was variable in these controls. It was more abundant in the aged than in adults, but a certain amount seems to be present in some of the ganglion cells of the sympathetic, at least in cases which I have been able to examine.

Reports of changes in the cervical sympathetic observed in different pathologic conditions affecting the system locally and generally, make it evident that as yet no change has been found that is peculiar to glaucoma. The findings in the cases of Ball, Ziehe and Axenfeld, Lodato and Cutler, are uniform in regard to the hyperplasia of connective tissue. This was also found by Petrow in cases of constitutional syphilis, and by Pio Foa in patients with various diseases. Slight infiltration of small cells does not appear to be peculiar to glaucoma.

---

[23] B. Onuf and Joseph Collins: "Experimental Researches on the Cervical Sympathetic," etc., Archives of Neurology and Psychopathology, vol. iii, Nos. 1 and 2, p. 217.

Changes in the nervous elements are reported by Ball, by Cutler and by Kuh. These were not observed by Ziehe and Axenfeld, nor by Lodato, except in the presence of pigment granules. Changes in the ganglion cells were observed by Petrow in individuals suffering from constitutional syphilis. The validity of the statements regarding the uniform increase of connective tissue is somewhat shaken by the results of Van Giesen's examinations, as no such increase could be demonstrated in the seven ganglia which he examined. Kuh also fails to mention an increase of connective tissue.

The testimony in our possession is not sufficiently conclusive to enable us to say that there is any constant change in the cervical sympathetic peculiar to glaucoma. Nor is it sufficiently conclusive to exclude the possibility of such constant change. Farther and more careful research is necessary; first, probably along the lines suggested by Dr. Van Giesen, viz., by means of the Ehrlich methylene blue method with fresh ganglia or by other equally delicate methods for the purpose of determining the conditions of the processes of the neurons and the cell structure, and, second, a study of the pigmentation of the neurons, which must be made in comparison with control studies.

[The discussion on the papers of Drs. De Schweinitz, Wilder, Ball and Weeks will follow the paper of Dr. Wilder next week.]

---

# PATHOLOGY OF INEBRIETY.*

T. D. CROTHERS, M.D.
SUPERINTENDENT WALNUT LODGE HOSPITAL.
HARTFORD, CONN.

The pathology of inebriety is the story of a long series of degenerative changes extending over many years, and also the record of brain storms and explosive liberation of nerve energies acting on defective cells and nerve centers. In all instances these changes appear in the walls of the blood vessels, the nerve cells and dentrites. The inebriate whose brain and body after death exhibit a confused mass of wreckage which the pathologist is often unable to trace back to the exact causes and conditions, has always sclerotic conditions of the large and small arteries, together with atrophic and hyperatrophic states of the heart, kidneys and liver with fatty degeneration, and calcification of the coats of the arteries. These organic changes are so frequently present in inebriates that they constitute a marked pathology which is traceable to the use of alcohol.

A large number of alcoholics die from acute diseases, and many of the organic changes found are referred to other causes, hence a distinct pathology is not often recognized. The more modern views of alcoholic degeneration indicate that the first pathologic changes following the use of spirits appear in the walls of the blood vessels, particularly in the vascular and capillary circulation of the brain.

The special action of alcohol on the vasomotor centers, paralyzing and diminishing the caliber of the arteries and capillaries, both obstructs and changes the uniformity of the blood current. This is followed by defective nutrition and accumulation of toxins, also a diminution of the power of elimination. The conclusions of the London Pathological Society, which have been sustained by modern authorities, agree that the first action of alcohol in the body is checking oxidation, diminishing the oxygen-carrying properties of the hemaglobin and retarding the elimination of carbon dioxid. (2) This action is that of a corroding tissue poison by the absorption of water at every point of contact with the cells and tissues. (3) It is a functional poisoning, depressing, checking and changing the natural activities of the organism. The corrugation of the cells and nerves with fibrous and fatty deposits and low states of inflammatory action are the common results. Dr. Andriesen, the pathologist of the West Riding Asylum of England, concludes an exhaustive study of the injuries following the use of alcohol as follows: "There can be no doubt that alcohol taken in the body has a specific influence over the nutrition of the nerve cells, impoverishing and starving them, cutting off and diverting the dynamic forces followed by a shrinking and atrophy of both cell and nerve." Dr. Berkeley of Johns Hopkins Hospital has added to these some new studies of his own, showing that alcohol in the system has a peculiar eroding action on the cells. At first this is confined to local centers, which increases until finally a large part of the brain becomes affected. Dr. Van Gieson of the New York Pathologic Institute in many new researches with new methods of staining describes the altered condition of the blood cells and fibers which exists, and concludes that alcohol first acts as a corroding destructive force on the nutritive cells and centers as well as on nerve tissue. More recently these views, while being confirmed, have led up to other studies showing that the walls of the capillaries are most seriously affected by the irregular and convulsive flow of the blood currents. Alcohol not only produces increased functional activity with its irritation, but is soon followed by diminished force and power extending to states of palsy.

In these conditions the nutrition is disturbed and the irritation may concentrate and appear in certain brain areas, which from unknown causes are more vulnerable than others. There can be no doubt that toxemias of gastro-intestinal origin are very potent factors in producing favorable conditions for the increased corroding action of alcohol. Heredity, syphilis and many other causes often leave brain centers defective and on the borders of acute organic degeneration. The use of alcohol by paralyzing the vasomotor functions controling the contraction and dilatation of the walls of the blood vessels favors the beginning of organic changes in the capillaries and arteries which extend to the nerve cells.

The power of contraction and dilatation so prominent in the heart extends to the minutest blood vessels, and resembles a chain of local hearts controlling the blood pressure and regulating the rhythmic flow of the current according to the influences of heat and cold, irritation, nutrition and rest. Hence a process of actual differentiation concerning the movements of the blood in the capillaries is going on continuously. This process includes oxidation, nutrition and elimination, and its disturbance and irregularity is registered in the minutest arterioles as well as in the larger vessels.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

Arteriosclerosis, the most common disease found in all inebriates, is degeneration of the structure of the walls of the arteries beginning in the capillaries of the brain and extends back to all the larger vessels in fibrinous deposits. When the blood current is loaded with toxins and defective nutrient plasma it moves in an irregular impulsive manner, hence the nutrition of the parts to which the blood circulates and the uniform flow of the current is disturbed. There is diminished oxidation, defective control and elimination. The red congested appearance of the face in persons who use spirits shows this condition. The dilatation of the capillaries is not due to the increased activity of the vasodilator nerves, but to a paralysis of the vasoconstrictors. This nerve action becomes intermittent, then increases to a degree of partial paralysis. The nutrition of the artery is affected and fatty degeneration follows with calcification of the middle coats of the artery, and increasing formation of fibrocellular tissue. The supply of nutrient plasma is diminished and the channels for obtaining this supply are modified and disturbed. Dr. Woodhead says: "I have been able to demonstrate that the walls of the blood vessels are the first to suffer organic change from the action of alcohol. Such changes occur first by a thickening of the inner coat followed by proliferation of the endothelial cells, then a thickening of the intima and adventitia, also wasting of the muscular fibers. This cellular increase is a veritable connected tissue group of degeneration. First it is proliferation of the endothelial and connective tissue cells around the connective tissue spaces, and secondly it is an accumulation of waste products. In some instances this may go on slowly, in others rapidly. Sometimes it attacks the liver; always the parenchymatous tissue, and in others the kidneys. In all cases these changes are seen in the capillaries of the brain. In the chronic form the muscular coats of the walls of the vessels disappear and the fibrous tissue is increased. The liver cells become atrophied, and fatty infiltration and degeneration follow. This formation of fibrous tissue is uniform, particularly in the heart, kidney, liver and blood vessels, also in the sheaths of the nerves. The lymphatics are also affected." The increased action on the heart interferes with the nutrition of that organ. The coronary artery is diminished in caliber and capacity to transmit the blood current, hence the increased heart's activity is followed by increased exhaustion. In all cases of inebriates the heart is either atrophic or hypertrophic, and both the quality and quantity of blood needed to supply its nutrition and carry away the waste is interfered with. The result is dilatation, deposits of fatty cells in the place of muscular fiber. Both the liver and kidneys suffer in the same way from increased work with impaired circulation and faulty nutrition. In the arterioles and capillaries the same disturbance follows, and the walls of the arteries are thickened or thinned. The postmortems of inebriates frequently show small ruptures and occlusions where certain areas which were cut off have been supplied by a collateral circulation. The result of these organic changes is anemia and exhaustion with increased use of spirits. Every intoxication from alcohol is a paralysis of the walls of the blood vessels and diminution of the nutrient plasma by interfering with its quality and absorption. This paralysis is in all cases either general or local.

In its general action profound stupor and coma follow, and in its local action excitement, delirium and delusions mark the character of the disturbance. This palsy is often due to the direct action of toxins in the blood both formed within and without the body, acting as irritants on localized centers. A number of authorities have shown that these poisons affecting protoplasm cells and dentrites are followed by great changes, sometimes by swelling and always contraction of the dentrites with tumefactions and fibrous growths. Bevan Lewis describes this condition as due to the swelling and subsequent contraction of the dentrites and the atrophy and shrinking of the cell walls. The serum infiltrations commonly found in the brain of alcoholics, together with the fibrous arteries, sclerosis of the nerves and capillaries and sclerotic state of the liver and kidneys all indicate a distinct pathology of inebriety. Why one organ should be more seriously affected than another is not yet clear. Why the heart should become enormously atrophied and the liver and kidneys remain normal in size and not seem particularly affected only in their functional activities and *vice versa* must be answered in the future. Outside of the gross appearance registered in the artery walls and the organic changes there are pathologic indications of psychic palsy which is common, although not studied. It is not known whether these alterations in character, consciousness and the higher psychic senses precede or follow the organic changes in the blood vessels and blood circulation.

In some instances they are traceable to defects of nutrition; in others to stress and strain following the sudden accumulation and liberation of nerve energy, also the association and disassociation of sensory activities. The general uniform paralysis of the senses following the use of small quantities of alcohol open up a new field for psychologic study. Kraepelin's studies have shown that the sight, hearing, touch, taste and smell, also the muscular power, are diminished and seriously disturbed by the use of a single ounce of ethylic spirits. This can be measured with instruments of precision.

In the laboratory the personal equation of the person experimented on is ascertained, then measurements of the senses after the use of spirits bring out this fact. In the more chronic cases these states of palsy are very apparent. The muscular paralysis is also very clearly defined, particularly on the heart and motor control. These measurements extend to time reaction, thought rapidity, memory, reason, judgment, and all the higher mental operations, and in all cases show that the action of alcohol on the higher brain is that of a depressant, anesthetic and paralyzant. This new field of psychopathology brings out some startling facts and explains in many ways the apparent diversity of symptoms of the action of alcohol on the brain centers. Why alcohol taken continuously in small quantities or at intervals to excess should so uniformly act on the higher brain or that part termed character, consciousness and ability to determine the quality of acts and duty, has been explained as the degeneration and disintegration of the last-formed and highest growth of the brain. Illustrated examples are very numerous of this fact and many explanations have pointed out states of fatigue, exhaustion and nerve instability which register themselves on these higher nerve functions in advance. Numerous experiments on the lower animals to determine the effect of alcohol have shown changes of cell and tissue with fibrous deposits and local inflammations clearly due to the toxic action of alcohol. The older pathologists whose experience was gained from the cadaver pointed out the uniformity of fibrinous deposits, serum infiltrations and calcification of the arteries with foci of old hemorrhages. The modern pathologists show the occluded capillaries of the brain, the thinned and thickened walls of the arterioles and the deranged vascular circulation with evidences of local inflammatory action, also from the new method of staining the cell degeneration and sclerosis of nerve fibers. The psychopathologist with instruments of precision shows the functional palsy of both the senses and the psychical functions of the brain. The chemicopathologist points out the complexity of alcohol, depending largely on the substance from which it is made and its special peculiar action on cell and tissue, producing new toxins with new effects and localizing them in certain sections according to unknown favoring causes. The anesthesias so marvelous in their effects due to the ethers of alcohol are of the same class and their effects are equally pathologic. These are all intimations of a new field for the exact study of the action of alcohol on the body which awaits farther and more exact studies. Some of the conclusions which I wish to make prominent are as follows:

(1) In all cases of inebriety there are marked changes in the capillary and vascular system of the brain. The walls of the vessels show fibrinous deposits and sclerosis. The nerve cells and dentrites are altered and retracted, in some cases permanently destroyed; in all inebriates shrunken and disintegrated states exist.

(2) The liver, kidneys and heart show diminution or enlargement with fibrous and fatty deposits. Both the organic and functional activity of the organ are changed and sclerotic states are present. Conditions of starvation and poisoning exist in all cases.

(3) Pathologic changes are apparent in the paralysis of the sense organs and the higher psychic functions of the brain. These conditions are so common following the use of alcohol, sometimes in its moderate use, but always when taken in excess, as to constitute a pathology that is traced directly to alcohol as the most prominent cause.

(4) The recent researches into the chemicophysiologic action of alcohol on the heart, blood vessels, cells and nerve fibers show a paralyzing and eroding action that can not be mistaken for any other cause.

The final conclusion is that the peculiar brain and nerve wreckage so commonly seen in persons using alcohol is due to the specific cause, alcohol following a uniform line of degeneration which is traceable with more or less exactness.

### DISCUSSION.

Dr. Albert E. Sterne, Indianapolis—I would take exception to the statement made by Dr. Crothers that the parenchymatous changes in the liver are primary. I would ask him whether such changes are not always secondary to an inflammatory process.

Dr. T. D. Crothers, Hartford, Conn.—Both primary and secondary. It may be either one or the other, according to the individual. There is no uniformity.

---

**Secret Remedies.**—Why can not physicians write their own prescriptions and adapt their remedies to the ever-varying exigencies of disease? Why should the vender of proprietary and secret remedies be upheld by so many of the profession, when Edward Jenner, after twenty-two years of laborious experimentation and research, freely gave the priceless boon attained to mankind, and when he could have made countless billions of money from the whole world by dispensing it as a secret and sovereign remedy against a loathsome and desolating scourge?—William T. Howard before the Maryland Medical Society.

## CARCINOMA OF SPINE AND MENINGES SECONDARY TO CANCER OF THE BREAST.*

F. SAVARY PEARCE, M.D.
Professor of Nervous and Mental Diseases, Medico-Chirurgical College,
AND
A. C. BUCKLEY, M.D.
Adjunct-Professor of Histology, Medico-Chirurgical College.
PHILADELPHIA.

*Ambulance History.*—Susan R. White, aged 70, housework, admitted to Philadelphia Hospital, Feb. 8, 1902. Duration of illness: four months; one month in bed. Symptoms: Pain in chest, pain in back, vomiting and diarrhea, severe pain over precordia and stomach, sharp pains in the leg at one time. She has had a lump in the breast for three years. Bowels and urine are not under her control. Both legs are paralyzed; anesthesia is present up to the waist line.

*Hospital Record.*—(By Dr. Blayney, interne,) Chief complaint: Anesthesia and paralysis of the lower extremities.

*Family History.*—One sister died of inflammation of the lungs (phthisis it is supposed); one sister died of scarlet fever; another of "cold"; one brother died of pneumonia.

*Past Medical History.*—She had the ordinary diseases of childhood, and rheumatism.

*Present Illness.*—Last November she was taken with pain in the hips; after the pains ceased the track of the pain would be very sore. The anesthesia and paralysis came on suddenly. She lost control of feces, then of urine. She lost control of feces before the paralysis came on. She had pains in the shoulder and back, had a creeping sensation in the left side which became better on pressure. She was sleepless for three weeks before entrance to hospital, and had the dry mouth of dyspepsia.

*Physical Examination.*—Emaciated, aged white woman; chest emaciated; heart seems to have a systolic murmur; lungs resonant; liver and spleen apparently normal; pupils seem dilated, haze around edge of cornea; pulse soft, regular; tongue dry, with light-brown coat; extremities atrophied; knee-jerk absent in the left leg, present to a very slight extent in right. Anesthesia exists to waist or slightly below umbilicus. She said she felt a pin stick her on the foot of right leg. She can move toes of right foot very slightly, those of left foot not at all. Plantar reflex is gone. She has incontinence of urine and feces, and has a sore over crest of ilium on the right side, also a sore over the sacrum. She has a nodule in left breast, and looks pale and emaciated.

*February 21.*—Patient does not feel the prick of a pin on either sole of the foot, but does have occasional extension reaction. Knee-jerks are absent. Supra-orbital reflex is present. Pupils respond normally. Patient is very feeble and cachetic. Looseness of bowels exists, probably largely due to relaxation of sphincter ani muscle.

*February 22.*—Patient is becoming more cachectic and growing weaker. There is a great tendency to decubitus where pressure is slightest. Does not feel when sole of foot is touched, but Babinski sign is present.

*February 27.*—There is a great humping of the muscles of lower extremities at site of blister which was present on admission; over right ilium there is a large bed sore. Patient is very weak, and is taking very little nourishment.

*Detailed History.*—(As taken by Dr. F. Savary Pearce.) The patient was always well up to last November (three months before admission), when she complained of pain and weakness in her legs, which came on gradually, and also of pain in her back; there was no history of any injury. She has been confined to bed since. For the last ten days she has suffered from nausea at times; retching and severe diarrhea. She has complained of pain radiating across the chest from one shoulder to the other; also of pain in the lumbar region, which she declares is constant. She has had no control of bowels or bladder for eleven days; she has not been sleeping well.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

*Examination.*—There is paralysis of lower portion of body; legs are flaccid; no sensation to touch, heat or pain from umbilicus down. Knee-jerks are absent on both sides, as are also the Babinski sign and ankle clonus. Pupils are slightly dilated, equal, react to light and accommodation. Tongue is protruded straight; no tremor; slightly coated. She has a hard nodular tumor in the left breast, upper and outer portion, for the last three years. It has not been growing rapidly lately; there is no pain unless she hurts it. She had a bedsore in sacral region on admission. Heart sounds are weak, slight accentuation of second sound; somewhat irregular. Arteries are atheromatous; arcus senilis. There was marked anterior curvature of spine beginning at ninth dorsal and extending to vertebra prominens; considerable tenderness over lowermost portion of curvature, but no true kyphosis or palpable tumor about the spine. Anesthesia posteriorly extends to a horizontal line just below the iliac crests, in front to a horizontal line apparently one-half inch above umbilicus. There is an ulcer in the right lower quadrant of abdomen just internal to anterior superior spine. Patient breathes well by diaphragm. There is a diffuse semicrepitant mass in the epigastric region extending from the umbilicus up three fingers' breadth and shading off in lateral region; it seems to be slightly movable and to move with respiration. The sensation of heat goes below that of sense of touch. She has had considerable pain in the past in the lumbar region. Tapping patellar tendon gives pain in the back. Atrophy of all extremities is symmetrical. There is a slight tendency to extension of toes.

*Diagnosis.*—Compression myelitis or metastatic growth with compression. *Clinical Diagnosis.*—Myelitis.

*March 21.*—Patient had grown very weak, and toward the last refused all nourishment. Pain has been much less marked the last few days. She died this morning.

*Autopsy.*—(Made by Prof. Joseph McFarland.) The woman was greatly emaciated. Pleural sacs contain very little fluid; cavities dry in appearance. Left pleura contains very strong adhesions and can only be separated with difficulty. Right contains only a few adhesions. On both pleuræ the parietal portions were dotted over with small tumors, from the size of a pea to one centimeter in diameter, these being far more numerous in right pleura, there being only two or three in the left side and the right containing eight or ten. On section these were found to contain a semisolid cheesy material. These tumors did not involve the visceral pleuræ.

In left breast, about one and one-half inches to left of nipple, was a hard tumor about two inches in diameter. Skin strongly attached to tumor, but said tumor was freely movable over underlying tissues. On section tumor was found to cut with resistance, having a grating sensation; cut surfaces pale in color and very resistant to touch; skin strongly adherent to growth, being incorporated in its substance. (Saved for microscopic study.) The fourth and fifth ribs (left side) beneath site of tumor were softened, and on pressure a cheesy material would appear on their surfaces. (A portion of fourth rib saved for further study.)

On section of vertebral column and removal of cord there was found in middorsal region a small portion of cord about 0.5 centimeter in length, which was softened in appearance and to the touch. Above and below this portion of the cord for some distance there were strong adhesions; also the vertebræ in this region—four or six in number were softened in their bodies—a probe being readily thrust into them, showing distinct evidence of disease of the bones.

### PATHOLOGIC FINDINGS (BY DR. A. C. BUCKLEY).

The interest, from a pathologic standpoint, centers about the spinal cord and its membranes. On gross examination there is to be seen on the anterior surface of the dura a mass of neoplasm about 5 mm. in thickness, extending from the tenth to the twelfth dorsal segments. The dura itself is considerably thickened. There can be seen clearly defined an ascending degeneration, limited to the postero-median columns, throughout the cervical region, and in the dorsal region as far as the eighth segment. At this level the lesion extends laterally, involving the postero-external columns, from which the gray substance can not be differentiated with the unaided eye. In the lower part of the tenth and the upper part of the eleventh dorsal segments there is an apparent diffuse myelitis. Below this there are distinct lateral lesions (descending degeneration).

*The Neoplasm.*—The pathologic material, consisting of the primary breast tumor, a fragment of the fourth rib and the spinal cord, was prepared as follows: The tumor and the affected rib sections were stained with hematoxylin and eosin; the cord sections treated with hematoxylin-eosin, nigrosin and the Weigert-Pal methods of staining. The sections from the primary growth show it to be of a pronounced scirrhotic type of carcinoma; indeed, in the part of the growth examined the connective tissue far exceeds the epithelium.

Sections made from the affected rib show the cancellated substance of the bone to be entirely replaced by a mass of carcinoma cells, which in many places have a distinctly alveolar arrangement, the epithelium approaching the columnar type. The compact portion of the bone is reduced to a mere shell. Where the bone has been reduced to small osseous islands, there are clusters of epithelial cells within the bone substance.

The neoplasm, in all probability, affected the rib by direct extension, since it occupied a position immediately beneath the primary tumor.

The pathology of the spinal cord closely resembles that of a similar case which I have reported and to the full description of which the reader is referred.[1]

*Cervical Region of the Cord.*—In sections taken at the highest part of this region the changes are pronounced but not widespread. The pia is thickened; the anterior sulcal vessels thickened, though the intima appears normal. The trabeculæ formed by the pial extensions are much stouter than normal, and there is a general interstitial overgrowth in the entire cross-section of the cord. The nerve fibers in the white matter of the postero-median columns are distinctly degenerated, as is shown by the Weigert-Pal method of staining, the nerve fibers being replaced by a neurogliar overgrowth. The nerve roots are normal.

Lower in the cervical region (about the third segment) the amount of degeneration in Goll's column is greater than that in the above sections, and the nerve roots contain an interstitial overgrowth of fibrous tissue and round cells. Specimens stained with nigrosin show the axis cylinders to be intact in the nerve roots. The gray substance shows no distinct changes other than vascular dilatation and a slight round cell infiltration. The central canal is not patulous, being occupied by a mass of small round cells.

*Dorsal Region.*—The lower segments contain the greatest amount of destruction; the tenth, eleventh and twelfth segments. The upper half of the eleventh segment contains very few normal nerve fibers, there being practically a transverse myelitis. The membranes are thickened and the nerve roots degenerated to a greater or less degree, no doubt having been affected by the inflammatory process in the meninges. The muscular tunics of the blood vessels in the nerve roots appear to have undergone a hyaline degeneration, as they stain very faintly. Other vessels, such as the sulcal vessels, in the same sections stain well. On the anterior surface of the dura there is a mass of epithelioid cells, corresponding to the neoplasm mentioned above, which contains elements similar to those in the breast growth and the affected rib. The cells are densly arranged in stout bands of fibrous tissue. In some areas there is a distinct alveolar arrangement.

---

[1] Jour. of Nerv. and Mental Dis., April, 1902.

The degenerative process affects chiefly the crossed pyramidal tracts in the lower half of the eleventh and in the twelfth segment. There is a marked vacuolation of the white matter and round cell infiltration. A slight interstitial overgrowth and increased vascularity are the changes in the gray substance in the dorsal part of the cord.

The position of the greatest amount of destruction to the cord substance is in the upper part of the eleventh segment, in which there are comparatively few normal nerve fibers in the entire cross section. There are scattered patches in the lateral and posterior columns, in which the destructive process has progressed very rapidly, as is evidenced by the presence of masses of granular debris instead of the vacuolation and interstitial overgrowth described above.

*Lumbar Region.*—It will be noted that following the transverse myelitis in the eleventh dorsal segment, there was an ascending degeneration; likewise below the level of greatest destruction, there follows, as usual, a descending degeneration. This in the lumbar region is not so marked as in the upper segments. In sections at the lumbar swelling the greatest change occurs in the nerve roots. The blood vessel in the fasicles are dilated and filled with blood. The majority of the nerve roots are the seat of an interstitial overgrowth varying in degrees, and much more marked on one side than on the other.

### CONCLUSIONS.

We submit the following thoughts in concluding the study of this case of secondary carcinoma of spine and meninges, viz., the undoubted metastatic origin of the bony and meningeal growth from the tumor of the breast as shown by the alveolar arrangement of the cancer cells in all situations affected.

Secondly, from the necessarily imperfect clinical history (since the patient was apathetic and in extreme asthenia and cachexia when admitted to the hospital) it would seem that pain of root irritation of girdle type was the most prominent spinal symptom from the first, and was persistent.

Therefore, in the diagnosis of spinal meningeal growths, this case (with another of pedunculated spinal tumor already reported) would go in evidence that pain from the outset is an important sign of such secondary nervous invasion.

### DISCUSSION.

Dr. H. T. Pershing, Denver—I have seen a case of recurrent carcinoma of the left breast followed by symptoms of myelitis involving the dorsal region of the cord and causing complete paraplegia, with loss of control of the bladder and bowels. There was some pain, but less than I expected in such a case.

Dr. F. S. Pearce—I am sorry I can not give a more accurate clinical study of this case, but when the patient was brought to the hospital she was practically unable to describe her symptoms and a thorough examination record was out of the question. In a case which I reported before the Philadelphia Pathological Society there was a primary growth involving the cord, and the patient complained of a considerable amount of persistent pain radiating about the body. The symptom pain may possibly assist us in differentiating between primary myelitis and the secondary form, due to metastases involving the meninges, as in the case I reported in this paper. More accurate diagnostic marks are what we must seek if we are to do these sufferers any good through surgery.

## REPORT OF TEN CASES OF MORPHINISM.*

A. J. PRESSEY, M.D.
CLEVELAND, OHIO.

The cases here reported have been selected from among many others which perhaps might be in themselves more interesting; but it has been my aim to select only such as would demonstrate the fact that many of the cases which appear to be the most hopeless will, when properly treated, become good and respectable citizens. A certain percentage of these patients may be restored to perfect health, physically, mentally and morally, and will remain so, regardless of the quantity taken, the length of time used, the manner of administration or the age. Just what that percentage is I do not know. It is with me an utter impossibility to even venture a guess as to who will remain free from the addiction and who will, as soon as the opportunity presents itself, relapse into the former condition. Being unable to distinguish between them, there remains only to do as we would with patients suffering from typhoid fever or pneumonia—treat every case and hope that he will recover and will not relapse. In reporting these cases I will give only a short description and history of each one, and I will not discuss treatment further than that they were treated according to the methods that I have previously described[1] to this section.

Case 1.—Mr. F. F., aged 21, single, occupation painter, was admitted to the U. B. A. Hospital in the fall of 1895. His arms and legs were covered with needle abscesses, and each leg was wrapped in a flax-seed poultice from the ankle to the hip and each arm from the wrist to the shoulder. He was using this pus-covered territory for taking the hypodermics, and consequently made an abscess with nearly every injection. At the time of his admission he was using 60 grains of morphin hypodermically every twenty-four hours, having chills and fever, with a temperature going as high as 105. Thirty or forty abscesses were freely opened, and he had no further trouble with the chills and fever. He had been addicted to the drug for about four years. The morphin was reduced to 1/120 gr. at the end of about 8 weeks, when it was entirely withdrawn. He remained in the hospital six weeks longer, when he was discharged and soon went to work at his trade. He has since married, and is the father of one healthy child. His childhood was not spent in the best of homes nor his youthful days with good associates, nevertheless he is now an industrious man and a good citizen. He appears to be in perfect health and tells me that he never thinks of morphin more than as though he had never used it.

Case 2.—Mrs. M. N. came for treatment in the spring of 1895; aged 30, married, general health good, occupation landlady, had used the drug six years. At the time of admission she was taking by mouth about 15 grs. of morphin per day. Five weeks were occupied withdrawing the morphin, and she remained two weeks afterward. A short time after her return home she was taken with sciatica. Her physician was true to her and did not give her any narcotic, but a friend and neighbor, who was an addict, after offering her morphin several times, finally persuaded her that one dose would do no harm and would give her great comfort. This manner of talk to one in pain and one who was almost persuaded that she was obliged to have the drug was enough, and she was again in the morphin habit. As soon as she was fully recovered from the sciatica she returned for treatment for morphinism. In four weeks she went home free from the addiction, and has remained so since. At the time she left my place she weighed 128 pounds, which was 10 pounds more than she weighed when she came. Her present weight is 206 pounds and she is in perfect health.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

[1] The Journal A. M. A., Nov. 16, 1901, p. 1292.

CASE 3.—Mr. C. P., age 73, farmer, married, came to me in the spring of 1896. Seven years previous to that time he had had an attack of la grippe which had left him with an aggravating cough, and little strength and more or less neuralgic pains. His physician had given him a prescription containing a small amount of morphin. While the prescription was often changed in other ways, the opiate was continued in increasing quantities for seven years. During this time his health was very bad, being confined to the bed for fully one-half of the time and the remainder of the time unable to get out of the house except for short rides. Finally, in the fall of 1895 he went to California in the hope that the climate would help to restore his health. He had never up to this time suspected that he was addicted to morphin. He had taken enough medicine with him to last three weeks, and when that was gone he became very sick and was obliged to call a physician, who soon found that four grains of morphin would make the patient very comfortable and strong enough to get up and be around. After becoming convinced that he was a morphinist, he came back east and placed himself under my care. I withdrew the morphin very gradually and discharged him cured at the end of fourteen weeks. He improved rapidly, and in six months he was as well as most men of his age, and kept well until this spring, when he died of apoplexy.

CASE 4.—Mr. C., age 63, had contracted the habit through constant and long-continued use of a patent medicine that he was taking for some real or imaginary nervous trouble. When his physician found that he was drinking two or three bottles of this nostrum every day he soon discovered that he was addicted to the use of about four grains of morphin in twenty-four hours. His physician told me that for weeks he had been walking the house and moaning in a nervous and despondent manner which was pitiable to see. This despondent condition was probably caused both by taking the overdose of the drugs contained in the nostrum, aside from the opiates, and also by not getting enough of the morphin to satisfy the requirements of the habit. He came for treatment in May, 1897. I made no effort to reduce his dose for three or four weeks until he was in a better condition, when I reduced it very slowly, and discharged him at the end of eighteen weeks. He has since remained free from the addiction and has enjoyed very good health.

CASE 5.—Mr. B. came for treatment Jan. 20, 1898; single, aged 32, occupation gambler, very much emaciated, had used morphin twelve years. Was taking at the time he came for treatment 40 grains of morphin hypodermically, and drinking two quarts of whisky every twenty-four hours. His condition was apparently alarming. He had no appetite, could take no solid food and the stomach rejected most of the liquid food that we persuaded him to take. I very much feared that he would have delirium tremens, but he did not. I gave him whisky in reduced doses for ten days, then withdrew it. I gradually reduced the morphin until the first day of May, when he was taking only 1/240 of a grain at a dose, then discontinued it. At this time he had gained 35 pounds. He remained with me for four weeks longer and went away in excellent condition. It is now over five years since he was treated, and I have seen him in the past few days and he is the picture of health. He tells me that he never thinks of either the liquor or the morphin with the least degree of temptation. This seemed to me to be one of the most hopeless cases that I had ever treated.

CASE 6.—Mr. H. came for treatment Dec. 22, 1898; age 51, had taken cocain for eight years and morphin for many years longer. He never would tell me how long he had used morphin. At this date he was taking three grains of cocain and ten grains of morphin per day, but this was a reduction. He had taken much larger quantities. For two months before coming to me the patient was treated by an Eddyite. How much that had to do with reduction of his dose I do not know, but after he left my institution the Eddyite claimed that she had cured him of the habit by absent treatment. Formerly he had been a very social man, a pleasant and agreeable companion, but for a few years previous to taking treatment he had become almost a hermit; would lock himself in his rooms and scarcely see any one at all for weeks at a time, not even admitting his wife when she brought his meals. He is a successful merchant in our city, but during this period his business manager was the only person who would see his face for days. His addiction was complicated with chronic ulceration of the legs. There were five large ulcers on each leg, which covered nearly one-half the surface between the knee and the ankle. These healed very rapidly when they were given proper care. I withdrew the cocain at once, reduced the morphin very gradually to 1/160 of a grain at a dose and March 28 withdrew it altogether. He remained with me about a month after discontinuing the morphin. It was three months after leaving me before he went to his store. Since that time he has paid strict attention to business and is as fond of society as ever. After more than four years he is now apparently in perfect health.

CASE 7.—Mrs. D., age 49, married, had taken laudanum for eighteen years, health very poor, had been under the physician's care for about half the time for twelve years; came to me for treatment Dec. 27, 1898, at which time she was taking three ounces of laudanum a day. I gave her morphin in place of laudanum, and reduced the quantity to 1/120 of a grain at a dose by March 21, about eight weeks after commencing her treatment, when the morphin was discontinued. Her health and strength had improved constantly from the time that she came to me until she was entirely free from the morphin. She remained with me for five weeks afterward and went home in fairly good condition. After leaving my place she lived much of the time out of doors, driving about the country and assisting her husband at such work as she was able to do on the farm, and is at this time, and has been for all of these five years, better than she had been for twenty years previous. This patient, after she had made arrangements to come to me, was visited by her family physician and strongly urged not to try to get rid of the addiction, as he was very sure that in her feeble condition she would die, while she might continue to take the drug and live on, perhaps, for some years.

CASE 8.—Dr. B., 26 years old, single, came to me for treatment Jan. 27, 1898, taking ten grains of morphin a day. He had just previously spent fifteen weeks at another institution for the purpose of getting rid of the addiction and at the time of going there was taking thirty grains of morphin and from twenty to thirty grains of cocain per day. They had withdrawn the cocain and reduced the morphin to ten grains while under that treatment and then pronounced him incurable. Eight weeks after coming to me his dose was reduced to 1/120 of a grain and then withdrawn. He stayed with me for a month after discontinuing the drug and then went into the country to his father's home and worked on the farm until late in the fall. He is now practicing in our city, and seems as well and strong as he ever was.

CASE 9.—Mrs. B., physician's widow, age 53, general health bad, commenced using vaginal suppositories containing morphin twelve years before coming to me for treatment, for the past five years had used morphin hypodermically. Was suffering a great deal from pelvic trouble, headache and sciatica. She came to me Feb. 22, 1900. During her treatment she had several attacks of sciatica which prolonged her stay very much. She was discharged cured August 1. While this patient has not been cured quite three years, I wish to report the case for the purpose of showing that some patients will endure a great amount of pain after being cured of the morphin addiction and yet not return to the use of drugs. She has had many severe attacks of headache and has at times been confined to the bed for days with sciatica. She suffers almost constantly with an ovarian trouble, and yet she tells me that she has never had pain enough to tempt her to take morphin. While she is far from being well, she is much better than while she was using the narcotic.

Case 10.—Mrs. L., age 45, addicted to morphin eight years and to cocain for six years. At the time of admission for treatment, March 4, 1898, was using about 20 grains of morphin and from 30 to 40 grains of cocain per day. I have never seen another patient that was so badly troubled with cocain hallucinations as was this one. She imagined that she could hear persons talking about her constantly, and also that these persons could see her under any and all conditions. It was almost impossible to get her to undress to go to bed, as she was sure she would be seen by these imaginary persons; for weeks she could not be induced to take off all her clothing to be given a bath. She had taken treatment at three or four institutions for the purpose of getting free of the morphin. I am not sure whether or not she had ever been free of the drugs from the time she first began using them. Her mental condition was such that it made her an exceedingly difficult patient to care for. While she was entirely irresponsible, her cunning seemed to be more acute, and twice during her treatment she stole away, went down town and loaded herself with morphin and cocain. It was six months before I was able to get her free from the drugs. The hallucinations had grown gradually less and yet she was not entirely free from them at the time she left my institution in November. She could still hear whisperings and yet she realized that there was no person there, and understood that it would be impossible for one to be whispering and she be unable to see them. She remained in the city with a sister for two months and then went to London, England, where she visited relatives for three months. When she returned she was still annoyed with hearing whisperings, although these were all the while growing less. Up to this time she had had plenty of money. She had been married to a man of means, but two or three years previous he had deserted her. As a result, on her return from England she was penniless. She went to Chicago to seek employment. Being an intelligent and bright woman with good address she soon found work. To-day she is earning a good living, is perfectly contented, and says that she never was as well and happy as she has been since being free from the addiction.

While experience teaches us that many of these patients will relapse, yet I am sure that we are unable to select any particular person and declare his case to be hopeless.

There are probably few persons who would not prefer that a friend would contract diphtheria or smallpox rather than the morphin addiction, after understanding fully the misery suffered in mind and body by a morphinist. I practised general medicine for twenty years, but I do not believe that I have ever seen any other class of patients that were more anxious to be free from their ailments than are drug addicts; and yet the medical profession does not appear to be as much interested in them as their needs demand. Possibly this is so because the disease is often self-inflicted. I believe it is true that there can be as large a percentage of them restored to perfect health as there can be in the case of other patients suffering from some diseases where heroic efforts are being made to relieve suffering or save or prolong life. Hundreds of patients all over this country are to-day treating themselves with some secret or patent nostrum for the relief of this awful condition, not one of whom will be cured, but will go from bad to worse. If they are ever restored to health they must be under the control of some person other than themselves. It would seem to be plainly the duty of every physician to treat these, as it is to treat patients with other diseases. If circumstances are such that he can not give them the attention that their case requires, then it is his duty to give them such advice as will lead to their recovery.

900 Fairmount Street.

## DISCUSSION.

Dr. George E. Pettey, Memphis, Tenn.—In my experience, the prognosis in these cases depends more on the cause of the formation of the habit than on the condition of the patient or the quantity of the drug he is taking. In some cases the habit is associated with a moral perversity or mental obliquity, and no matter what method of treatment is employed or to what extent the normal physical condition of the patient is restored, he will very likely resume the use of the drug under very slight provocation. On the contrary, those who become addicted to the habit accidentally, through the course of a painful illness or injury, or through inadvertently taking the drug in some preparation not known to contain it, constitute a more hopeful class of patients. They recognize their condition as one of abject slavery, and are willing to do almost anything to free themselves, but they have not the mental, moral or physical power to do so. When such a person is put into good physical condition, there is little likelihood that he will return to the habit. In my experience, those who use both morphin and cocain are much more apt to relapse than those who use morphin alone. We find that physicians acquire the habit oftener without real cause than do any other class of patients. They are apt to take it first as a stimulant to sustain them during prolonged working hours, and then, through overconfidence, they continue the use of the drug until they become slaves to it.

Dr. A. J. Pressey, Cleveland, Ohio—I presume that in the majority of cases the morphin habit is acquired either through necessity or pleasure, and that the method of the acquirement has some bearing on the prognosis. In my paper, however, I included only those cases that appealed to me as hopeless, and in at least five of them there was no distinct cause or provocation for the formation of the habit. In the majority of cases, however, where a permanent cure is effected, the drug was probably first taken for the relief of some physical ailment.

---

# THE TREATMENT OF EMOTIONAL DISTURBANCES.*

HOWELL T. PERSHING, M.D.
Professor of Nervous and Mental Diseases in the University of Denver.
DENVER.

An emotion is much more than a state of feeling. Intense fear, grief, anger or even joy begins as a sort of cortical storm which involves an energetic disturbance of the entire body. Such a disturbance may be a very serious or even fatal complication of a pre-existing disease. Thus John Hunter, suffering from chronic heart disease and liable, when excited, to attacks of angina, said that his life was at the mercy of any scoundrel who should make him angry. While to all appearance in his usual health, he was debating a question of personal importance to himself at a board meeting at St. George's Hospital. One of his opposing colleagues flatly contradicted him, a cardiac attack came on, he instantly ceased speaking, went into the next room and fell dead in the arms of a friend.

Not many cases are so dramatic and angina is fortunately not common, but all patients are more or less emotional, and it would be difficult to find a serious medical or surgical case in which the patient's emotional state is a matter of indifference. It is, of course, true that mental disturbances are generally only a partial or incidental feature of disease and that treatment should be directed mainly by the cause rather than by the symptoms; nevertheless, there are many important symptoms or complications, such as hemorrhage, fever or pain, which must be specially studied from their own point of view, and so it is with the emotions, which are sometimes symptoms, sometimes causes of new complications, sometimes valuable remedies. The physician, moreover, is sure to influence the patient's emotions whether he intends to or not. He ought, therefore, to understand them and see that they are influenced for good and not for ill.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

Other agents, such as drugs or electricity, whose effects are rarely so profound, are carefully studied, but for some reason our profession as a whole has lacked either time or inclination for the systematic study of mental factors in the causation and modification of disease. It is safe to say that this defect will soon be remedied, and that the study of practical psychology will be carried on in the medical schools just as thoroughly and systematically as that of physiology or therapeutics. The purpose of the present article is to consider emotional disturbances as factors with which the physician must deal in every-day practice, and to classify the methods which theory and experience indicate as useful in treatment.

In all emotional states the physical disturbance, which is generally regarded as merely the outward expression of an inward feeling, is really an essential part of the emotion and is the cause, not the effect, of the feeling. To illustrate this theory of James and Lange, which is unreservedly accepted by Ribot, take any case of sudden fear. Suppose a man walking home at night is suddenly confronted by a robber who holds a cocked revolver at his head. Instantly the innervation of the whole body is changed. The heart is first arrested and then beats with wild irregularity; respiration, after a quick gasp, is shallow and rapid; there is a tendency toward both urination and defecation; the skin becomes wet and cold and its intrinsic muscles cause shivering and erection of the hairs; the voluntary muscles, weak and tremulous, waver between a tendency to headlong flight and complete paralysis. These motor and secretory reactions are instinctive, that is, they result from a prearranged, inherited mechanism in the cortex and efferent nerves, which is immediately put into action by the perception of the fearful object. Not until these motor reactions have taken place and the flood of sensory impulses from the disturbed heart, lungs, abdomen, muscles and skin has rushed back on the cortex is there any feeling of fear. Every other emotion normally consists of a similar process, perception or idea being the first, disturbance of the viscera and other organs the second, and the feeling peculiar to the emotion the last link in the chain of cause and effect.

It need hardly be said that all emotions having the same name are not precisely alike in different persons or in the same person at different times. Anything so complex must necessarily be subject to considerable variation. Thus in some persons the heart is predominantly affected in any emotional disturbance, in others the gastro-intestinal tract, in others some part of the genito-urinary apparatus, and so on. If an organ normally involved in an emotion be from any cause unduly irritable, it will react excessively, and the commotion may extend even to functions not normally involved, as when fear or grief precipitates an attack of neuralgia.

Emotions are contagious. An exhibition of fear excites instinctive fear in the beholder; courage in others inspires courage in us; a laugh spreads through a crowd, and so on.

The ways in which a physician may dissipate or control an undesirable emotion may be arranged under the following heads. It is necessary to keep these methods entirely distinct in mind, for, although we usually combine them in practice, the combination to be chosen varies greatly according to the nature of the case, and some one method is always the most important and so should predominate over all the others.

1. The idea exciting the undesirable emotion should as far as possible be removed and replaced by ideas of an opposite tendency, as when a patient who is frightened and depressed by the idea that he has heart disease is thoroughly examined and positively assured that his heart is perfect.

2. The motor reaction characteristic of the emotion should as far as possible be voluntarily suppressed and replaced by the motions and demeanor characteristic of the opposite emotion, as when a patient threatened with a hysterical spell forces himself to breathe deeply and slowly, relaxes the muscles and assumes a calm demeanor.

3. An exhausted and irritable nervous system must be rested, built up and soothed so as to make it less susceptible to emotional storms.

4. Poisons which irritate and depress must be eliminated, as in the so-called uric acid diathesis, uremia, diabetes, alcoholism, etc.

5. A diseased organ which sends abnormal sensory impulses to the cortex and thus causes the feeling of fear or of grief without such mental cause as would otherwise be necessary, must receive appropriate treatment, as in certain cases of disease of the heart, stomach, liver, intestinal canal or pelvic organs.

6. Other means proving inadequate, a painful emotion may be controlled by full doses of opium, as in the opium treatment of melancholia.

1. The first method, by which we seek to replace the exciting idea of an emotion with one of an opposite tendency, is the most obvious. Show the man who is afraid that there is no rational ground for fear, divert the attention of the person oppressed by sorrow to the cheering side of his situation, and very probably there will be a corresponding emotional change. Indeed, the method is almost too obvious, for many rely on it alone when physical remedies would be better. We have to apply this method most frequently to patients who wrongly believe that they are afflicted with a serious disease, especially disease of the heart or genital organs. In such cases, although a combination of resources is generally necessary, positive reassurance given after a thorough examination and repeated from time to time as its effect wears off, is often by far the most effectual remedy. A striking case came under my care five years ago.

Mrs. A., aged 55, whose home was in a Colorado town at an altitude of 8,500 feet, was told about ten years before, when consulting a physician on account of slight palpitation, that her heart was somewhat affected and that she must be careful. From this time on the fear of heart disease took possession of her and the heart seemed to grow steadily worse, especially when at a high altitude or on a journey. For two years she had felt compelled to live, with one daughter to keep her company, in the comparatively low altitude of Denver, while her husband and the rest of the family lived some hundreds of miles away. This was no self-indulgent whim, but a real hardship to her and to all concerned. Examination showed that the heart itself was normal, although sensitive to emotional changes, so the real problem was to restore emotional equilibrium. Positive and repeated reassurance, together with the cheering prospect of living permanently in her own home, was the main remedy, everything else being intentionally subordinated. In a few months she rejoined her family and continued to live with them in far greater comfort than when she was being treated for her imaginary disease.

Every neurologist will recall similar cases and we are all familiar with the despondent young man who thinks that his sexual organs have been ruined when they are in reality normal.

The same principle is applicable to the treatment of night terrors. Acting on a recommendation of Gowers, I have long treated such cases by giving any medicine that the general condition may call for, with the positive assurance that it will enable the little patient to sleep soundly, and the promise that a small sum of money will be given for each good night. The prospect of reward puts the child into a cheerful frame of mind as it is falling asleep, and no doubt favorably influences its dreams. The threat of punishment would, of course, make the attacks more frequent. The cases in which this method will not succeed are rare, and the same treatment will generally break up any form of hysterical attacks in a child.

Physicians are in danger of suggesting depressing ideas to patients without being aware of it. We receive and examine patients as a matter of daily routine, but to the patient an examination is a momentous occasion which makes him unusually sensitive to unpleasant suggestions. In the reception room the first thing to strike his eye may be a copy of Rembrandt's grim picture, "The Lesson in Anatomy," or a view of some famous clinic, or a pathetic scene about the bed of a sick child. The consulting room may be, as a popular humorist describes it, "the chamber of horrors where they keep the skulls and butcher knives." It ought to be needless to say that a patient's thoughts ought not to be turned toward disease and suffering any more than is absolutely necessary. Surgical instruments, anatomic and pathologic specimens and plates, books with gruesome titles and everything of the sort may very well be kept out of sight. On the other hand, all the decorations should be as remote from the idea of disease and as tranquilizing as possible. A physician in making an examination may very well drop an occasional reassuring word as he finds one function after another to be normal. He ought not unnecessarily to mention aneurism, Bright's disease or carcinoma; and he should set an example of unruffled serenity while showing a lively interest and human sympathy.

2. In many cases of morbid emotion the mere appeal to reason will not be sufficient, because the exciting idea is not a reasonable one. Few persons are so fortunate as to wholly escape fits of the blues which are wholly unreasonable. Many a neurasthenic knows perfectly well that he has no reasonable ground for fear, and yet is horribly afraid, just as we all have been at some time when about to speak in public. Here the second principle comes into play. The patient must suppress as far as possible the motor reactions of the depressing emotion and voluntarily imitate those of its opposite. The raw recruit about to go under fire, who is really badly frightened, but who resolutely steadies his trembling limbs, breathes regularly and marches erect, with a bold countenance, not only helps his comrades but also helps himself, for he has to a certain extent substituted the sensations of courage for those of fear.

The power thus to overcome fear grows rapidly with the successful exercise of it, and graduated exercises in putting on a bold front are a most valuable resource in treating neurasthenic fear. An intimate friend, who has for many years successfully practiced medicine under the burden of a multitude of unreasonable fears, tells me that he has derived most benefit from resolutely doing a little of whatever he happens to be afraid to do. It is important that a physician should not demand more of the patient than he can nerve himself to do, for one complete failure may demoralize for a long time.

The most brilliant success often follows the application of this principle to the treatment of hysterical attacks, providing the patient is mature enough and reasonable enough to make a vigorous effort. Convulsive hysterical attacks, both minor and major, are exaggerated emotional disturbances whose motor reaction is largely in the voluntary muscles, especially those of respiration. Let the patient note the first premonition of the attack and she will find that respiration is becoming rapid, shallow and jerky. It must be made slow, deep and regular by sheer force of will. When respiration has been attended to the muscles of the trunk and limbs will probably be found excessively contracted; each group must be voluntarily relaxed and then the breathing attended to again. These instructions, if faithfully followed, will stop any ordinary attack, and most patients can be made to follow them, especially if reassurance in adults or the promise of reward in children be skilfully combined. The following case will serve as an illustration:

A. B., male, aged 25, came to the County Hospital in Denver, March, 1898, to undergo an operation for the cure of convulsive attacks which were supposed to be epileptic. The convulsions were prolonged and violent, and they had become very frequent, but they were clearly hysterical; he was told that no operation could do him the slightest good, but that he could be cured by other means. This apparent underestimate of the importance of his case disappointed him and he left the hospital, but a few days later he came to my office and asked me to treat him privately. As the case seemed to be difficult, a great deal of care was taken to gain his confidence and to properly instruct him. Very soon afterward he had the beginning of an attack which he almost entirely aborted by voluntary breathing and relaxation. This greatly encouraged him, and the attacks soon ceased altogether. He returned to his home in a mountain town, and a few months ago I learned that he had passed an insurance examination, and had been free from attacks for the past five years.

3. In many cases of neurasthenia the two preceding, purely psychologic methods will not suffice. The cortex is in such a state of irritable weakness that the slightest cause of annoyance, fear or grief will have an excessive bodily reaction. In such a case shelter from annoyances, rest, sleep, an abundance of nitrogenous food and such medicines as strychnin, iron and arsenic are of the greatest value, but it is unnecessary to repeat here what is already familiar. One detail of treatment, however, I would like to mention. Small doses of opium (one-twelfth to one-sixth of a grain of the extract three or four times daily, about what would be used to relieve excessive cough) prevent the reaction to a large number of inevitable, trifling annoyances, and

thus give the patient a chance to rest. If such doses are properly combined with other remedies and the patient is not allowed to vary the number of daily doses, they involve no more risk of the opium habit than does the use of an ordinary cough mixture.

4. It is not necessary to say much about the elimination of poisons. Analogy leads us to believe that such terrible emotional disorders as melancholia, mania, acute delirium and transitory frenzy are forms of intoxication, although the poisons have not yet been discovered, and if the cause of any emotional disturbance is obscure we should always carefully consider the possibility of its being a poison of some kind. Byron is quoted as saying: "Talk about champagne! Nothing cheers the spirits like a dose of salts," from which one may safely infer that some, at least, of Byron's melancholy moods were caused by intestinal toxemia.

5. The ancient belief that localized disease of the abdominal viscera causes depression, fear or bad temper, is embalmed in the words melancholia, hypochondria and spleen, and in a general way it has been amply confirmed by modern observation. Part of the emotional effect of abdominal disease is probably due to the formation of toxic substances, but much of it is no doubt caused, as pain is, by the direct transmission to the cortex of abnormal sensory impulses. A diseased heart may also disturb the emotions in two ways: by failing to furnish the brain with a proper supply of blood and by sending abnormal sensory impulses. The altogether different effect of disease of the lungs is illustrated by the euphoria sometimes seen in pneumonia, and the proverbial *spes phthisica*. Although much has been written concerning the relation of mental symptoms to visceral disease, our knowledge of the subject is still vague and incomplete. The necessity of treating any local disease which depresses or irritates the brain, is obvious enough, but the causal relation ought to be very clear before serious operations are undertaken for the relief of mental symptoms. Many gynecologists have undoubtedly gone too far in removing the ovaries or uterus for the relief of mental disturbances, which were really dependent on quite different causes.

6. Finally, there are cases of emotional disturbance, more particularly of melancholia, in which psychologic methods of treatment are of little or no avail, and in which we are ignorant of the physical causes, and can attempt to remove them in only the most indirect and uncertain way. Here opium is a most valuable remedy, just as it is in cases of pain where the cause can not be removed. It not only relieves a considerable part of the mental suffering, but it also tends to prevent the physical deterioration.

## DISCUSSION.

DR. H. T. PATRICK, Chicago—I am in hearty accord with the principles and technic indicated in this paper, and would only add one point, and that is, the supplanting of a good idea for a bad one, or the removal of a fear by a process of demonstration. The mere suggestion or statement of the physician is often not sufficient. We must institute a process of education, and there is nothing better for that purpose than a plain demonstration. Frequently I take a patient who is convinced that he has heart disease for a vigorous run up two or three flights of stairs, or make him run a number of times back and forth the length of my office, in order to show him that he has a perfectly competent heart; to convince him that he can not have heart disease and do what he has done. Then we see the man who complains that his food remains in his stomach for two or three days; that he feels it there. I instruct him to eat a hearty dinner at 6 or 7 o'clock, and the next morning I wash out his stomach, demonstrating to him that the stomach is empty, and hence takes care of his food better than he thought. Then we have the patient who says he does not sleep. I instruct him to go home and stay up all night, and report to me the following morning. He does so, perhaps not having slept at all. I then instruct him to stay awake all day and the following night, and I usually find that he is unable to do so. When such a patient finds that he absolutely can not stay awake for two nights in succession, he will make up his mind that he is not going to die from loss of sleep.

DR. JOHN PUNTON, Kansas City—The profession generally has been very slow in learning the treatment of some of these emotional states, but I am hopeful that the treatment will be placed on a more ethical basis. If drugs will not reach the case, and surgery aggravates it, and massage and hydrotherapeutics have been appealed to in vain, we have still open to us a very potent method of treatment which is embraced in the term mental therapeutics. The application of this method requires tact and experience and good judgment. We are on the eve of a new departure in the treatment of these cases, which have heretofore baffled us, only to be cured eventually by the psychologic methods of the ordinary bold quack, much to the chagrin of the physician.

DR. B. F. TURNER, Memphis, Tenn.—Although the time has not yet arrived, and I doubt if it ever will arrive, when we can dispense with our materia medica, still the time is here to employ psychologic influences in the treatment of certain conditions. In fact, the time for its use has always been here, but psychology has been so much abused under the name of the various "isms" that it is difficult for the unfortunate sufferer who lends himself to it to distinguish between the true and the false. Will this particular phase of therapeusis ever be straightened out? Dr. Pershing referred to the beneficial influence of a cheerful attitude on the sick and suffering, but he made no mention of the occasional value of an attitude opposite to the cheerful. He said nothing about portraying to the young man who is on the road to drunkenness the evils that may result from the excessive use of alcohol. He said nothing about the possibilities of a life of lewdness. All these suggestions can be made valuable as therapeutic agents. The pity of it is that the laity will probably never be much better educated than it is to-day, and as long as that is so the charlatan will be able to impose on the credulity of the ignorant. I approve of Dr. Pershing's condemnation of the popular advertising mediums which are found in too many professional offices. The various apparatus and other articles in evidence in a physician's office are too often put there as cheap methods of supposedly enhancing his dignity.

DR. F. SAVARY PEARCE, Philadelphia—While the public press is willing to uphold the honest physician in the community, and will do it, it will at the same time not hesitate to publish the advertisement of this or that impossible "cure." Such advertisements have a great influence on the ignorant, and even on those who should know better. Our discussion on this subject will never amount to anything until we can educate the public. Every physician must share a part of the responsibility for educating the public. We are not physicians for money alone. We have a duty to the public to perform, and it should be done fearlessly.

A girl had middle-ear disease, and was treated by one of our best aurists. He operated on the mastoid, and curetted the bone, but the patient, though apparently well, still complained of pain. When I examined her, I made up my mind that there was no real cause for pain; that what she complained of was simply a "remembrance" pain. I took her into the hospital, and on the following day, in passing her in the ward, I intentionally struck her over the ear where she complained of the pain, but the blow did not hurt her, to her surprise. In the course of a few days she ceased to complain of pain, and was able to leave the hospital, a perfect demonstration of pure emotionalism.

DR. H. T. PERSHING—For two years I have been giving to our students in Denver a systematic course of lectures on psychology, as applied to the practice of medicine, and the main point I always emphasize is that mental influences are not to be used in a haphazard way. Psychology, just as is physiology, is a real science and a very important one for us to apply. Let the intelligent physician insist that its importance shall be recognized in our medical schools. The patient has not only a body, but also a mind, and we should not attempt to separate them. The daily newspapers and even the high-class magazines do much toward spreading broadcast the seeds of mental disease among the laity. The physicians should recognize the value of mental influences, and when a patient is in need of such treatment, he should receive the best possible from a regular physician, and not be turned over to the quack and charlatan. It is not necessary to resort to deception. You can do everything you wish and still be perfectly honest. Of course, the use of proper drugs is not to be neglected, but in my paper I purposely emphasized the importance of mental treatment. I think that anyone who has used the method referred to in treating hysterical paroxysms will appreciate its value. Just tell your patient that when the premonitory symptoms come on, he should not forget your instructions, but inspire deeply and slowly in order to avert the attack. Then if the voluntary muscles are tense, they should be relaxed. Of course, the general hysterical condition must also be treated, but mental influences are the essential factors in overcoming this condition.

# PULP HYPERTROPHY OF THE TEETH.*

OSKAR RÖMER, M.D.
STRASSBURG, GERMANY.

I was first led to the histologic examination of pulp hypertrophy by the desire to find the conditions of the nerve supply in this so highly-altered pathologic tissue; in the study of the nerves I found not only what I expected—partly complete absence of nerves and partly marked decrease of nerve fibers, thus explaining the great difference in sensitiveness—but also some other very interesting discoveries which I believe are new.

Pulp hypertrophy is to be considered as a new tissue formation due to chronic pulpitis from exposure through more or less complete destruction of the overlying protective tissues. This new growth consists of a comparatively coarse granulation tissue in which three layers can be distinguished. The outer layer consists of a thick stratum of white blood or pus corpuscles beginning to break down, then follows a somewhat wider zone consisting of a proliferation of endothelial cells and capillary vessels, which, seen with a less magnifying power, has almost the appearance of granular layer, similar to that before described in the so-called endothelial granuloma of the dental root. The third layer, which forms the chief mass of the tumor, consists of a coarse, connective tissue with dilated blood vessels interspersed with crowded round cells.

Up to the present I have studied about 30 different specimens mostly obtained in clinics, but for part of which I have to thank my colleagues. I have prepared them in the following manner:

First, I placed the whole tooth with the pulp *in situ* in a 10 per cent. formalin solution, then decalcified it in a 33 1/3 per cent. formic acid solution (which is, as a rule, accomplished in two or three weeks), then divided the tooth, together with the hypertrophied pulp, into two nearly equal halves. Of these halves, such as seemed most suited for further treatment for microscopic examination were taken. These were imbedded in celloidin and cut with the microtome into the thinnest possible layers and then stained partly with alum hematoxylin and picrofuchsin (Van Gieson) and part with Weigert's medullary staining process in which the nerves and their medullary layers appear as dark, blue-colored fibers on a yellowish background.

This shows that in so-called pulp hypertrophy (which arises like a fungus from the pulp chamber and generally fills the carious part crown of the tooth) nerve fibers are absent. In the pulp cavity itself and in the root canals, on the other hand, numerous nerve bundles are found according to the degree of degeneration of the pulp tissue. This degeneration consists in a transformation into granulation tissue, particularly where infiltration with round cells changes into granulation. The nerve fibers are already broken down or beginning to be degenerated, as shown by distortive interruptions and knot-formed swellings of the nerve fiber. Such degenerative processes of the nerves can best be seen in pulps which have been laid open by fracture in attempts at extraction and in which the superficies of the exposed pulp is changed into granulation tissue and pulp hypertrophy.

The study of preparations stained by the Van Gieson methods has convinced me the difference claimed by Rothmund and Arkovy between pulp hypertrophy and pulpitis chronica hypertrophica granulomatosa does not exist. By the pulpitis chronica hypertrophica granulomatosa is understood (according to Rothmund and Arkovy[1]) a granulating mass of the pulp from the size of a millet seed to a pea, soft with little consistency and extending over one or two pulp points. The pulp hypertrophy, on the other hand, which Arkovy calls pulpitis chronica sarcomatosa is a compact, dense neoplasm caused by proliferation of the pulp tissues, distinctly limited, generally smooth and only here and there slightly lobular, less vascular, extending over the whole pulp cavity, except perhaps some very slight portion, including the whole crown cavity of the tooth.

I find neither clinically nor histologically any noticeable difference in the two forms. Both forms of hypertrophic pulpitis differ only in their size and agree perfectly in their histologic structure. The fleshy round bean or hazelnut-sized pulp hypertrophy develops simply through its natural growth from the minute millet seed or pea-sized neoplasm. In both cases there is a degeneration of pulp tissue and transformation into a more or less coarse granulation tissue, which consists of connective tissue fibers with numerous blood vessels, round cells and proliferated endothelium and connective tissue cells.

The striking point in all the specimens is the richness of blood supply. The vessels are not only numerous but also dilated, almost like a hemangioma, so that after extraction of the tooth the hypertrophy loses half its volume.

In almost all cases of pulp hypertrophy there is found to some extent the formation of partly attached, partly free, pulp stones and calcareous deposits. This is in itself not astonishing, since in nearly all teeth which suffer from any kind of pulpitis calcic formations are present to the discomfiture of the investigator, and even in well-decalcified preparations they often cause inconvenient nicking of the microtome knife. But what is here remarkable is the fact that in many hypertrophied pulps such calcareous formations occur well above the pulp chamber and the hypertrophy itself. These calcareous masses or pulp stones are in part round or oval with distinct stratifications and partly irregularly dentated, and show cell inclusions similar to those which are found in the formation of secondary dentin inside the pulp chamber.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

[1] Compare Scheff's Handbuch, vol. xii, p. 297.

How can these things be explained? I believe the pulp hypertrophy only occurs in teeth the pulp elements of which possess great vital energy and capacity for regeneration and in which they can oppose special resistance against incoming bacteria and other morbid influences. If in such teeth from caries the pulp loses its defense (its secondary dentin cover) it is still able to defend itself by forming on its surface granulation tissue in thicker and thicker layers which will have to be called pulp hypertrophy. Even after fracture of the tooth by unfortunate attempts at extraction such pulp hypertrophies can develop, although in such case the pulp is certainly laid bare to a larger extent.

The formation of secondary dentin partly attached to the walls and partly free is to be considered an attempt at defense from external injury. The quicker the pulp is compelled to form secondary dentin the more irregular will be its formation, so the calcification does not follow regular rules and the dentin is not laid down in regular layers, but the pulp cells are included in rapidly-formed irregular dentin structure. Such pulp cells, so over-energetic in dentin formation, may here and there extend with the granulation tissue beyond the pulp chamber itself, and thus far away from their original site form on the crown of the hypertrophy such pulp stones as are shown in some of my specimens.

Some things shown appear at first rather difficult to explain. Thus in one case the surface is covered with regular stratified pavement epithelium instead of the usual round cells and pus corpuscles, also with the high papillæ which are typical of the gum tissue. How does this epithelium develop on the pulp? Usually the excised fragment of a pulp hypertrophy is readily distinguished from a corresponding fragment of an alveolar growth by the absence of epithelium. I explain the process as follows: Hypertrophied pulps are frequently ingrafted with alveolar growths, that is, when a pulp hypertrophy extends outside a pulp chamber over the corroded wall of the crown in contact with the gum tissue. Both are easily injured in chewing so that spontaneous autotransplantation from the gum tissue to the pulp hypertrophy occurs. Six months after preparing the one specimen I found another which demonstrated conclusively the truth of this conjecture. I have seen gum tissue grown over the completely destroyed crown of the tooth of which one was united with the broad surface of the pulp hypertrophy in the pulp chamber. The whole surface of this hypertrophy was already covered with epithelium of the same composition and height of papillæ as that possessed by the alveolar tissue. Later I had the opportunity to separate the gum overgrowth from the pulp and there remained then only the pulp hypertrophy covered with epithelium.

In conclusion, a few words on the therapy of pulp hypertrophies: In cases where the pulp has one of these growths (they are vascular and at the same time poorly innervated) they may be either simply amputated with a pair of fine scissors or pointed knife in the depth of the pulp chamber and then arsenic paste applied to cause necrosis of the root pulp, or the arsenic paste can be applied direct to the crown of the hypertrophy in order to destroy by necrosis the entire tissue. But there is no serious error, in my opinion, in avoiding the use of arsenic altogether, but simply cut off the top of the hypertrophy and cap the stump, or in very small hypertrophies after a thorough cleansing cap the hypertrophy as a whole and over this insert a filling or crown. The possibility of decomposition of the capped hypertrophy might be excluded since the tissue has already been shown to possess remarkable resistance.

# THE CONTROL OF PROSTITUTION AND THE PREVENTION OF THE SPREAD OF VENEREAL DISEASES.*

M. L. HEIDINGSFELD, PH.B., M.D.
Clinical Lecturer on Dermatology and Venereal Diseases, Miami Medical Colege, Cincinnati.
CINCINNATI.

This paper is presented under this double caption because venereal disease and prostitution are inseparable terms, and because the control of prostitution is engrossing the attention of most of the large and many of the smaller communities, solely for the avowed purpose of preventing the spread of venereal diseases. By far the more important of the two questions is that which refers to the prevention of the spread of venereal diseases; whatever preventative measures have thus far been instituted have been largely ineffective in character and have been directed against the chief source of infection, prostitution, with a view of either effecting its suppression or control. History is full of attempts of such manifold nature and character as to conclusively demonstrate that suppression is impossible and control impractical and at best of very doubtful value. I need only refer to a few well-known examples to convince the most skeptical that suppression of prostitution is not feasible. The stern and severe regulations of Maria Theresa, at Vienna, and the popes at Rome, were promptly followed by husbands prostituting their wives, parents their children, and by a rapid and alarming increase of venereal diseases. The history of the city of Bonn conclusively demonstrates that, however severe the measures for the suppression of prostitution may be in character, even to the degree of the infliction of the death penalty on the transgressors, they foster not only rapine, seduction, bastardy and infanticide, but an undue prevalence of venereal disease in its most aggravated form. Yet "prostitution must be regarded as the fountain-head, from which venereal diseases originate, and forms the main source of the unbroken vitiated stream of poison, which inoculates the living and contaminates the unborn."[1]

Hardly less unfavorable are the measures which, from time to time, have been and continue to be instituted, in most of the larger communities in this and many foreign countries, not for the suppression, but for the control of prostitution. Although measures for its control have been prepared with the greatest care and wisdom, and have been rigidly enforced with the most conscientious and painstaking effort, it is exceedingly questionable, even in the most favored instances, if the resulting good is ever commensurate with the effected harm.

The most efficient and most carefully exercised control, regulating the proper registration of all known prostitutes, their subjection to police surveillance, submission to careful periodic examination, and compulsory hospital treatment when diseased, even though it could materially diminish the danger of contagion from this particular class, would remain practically ineffective, because it would utterly fail to cope with that larger and more dangerous element, the clandestine prostitutes, who readily escape the most careful system of medical registration and examination and spread venereal disease without license or restraint. Control conditions, therefore, by reason of their irksome and burdensome character (restriction of personal liberty, infringement of private and constitutional rights), invariably augment the more dangerous class of clandestines, and drive those under control from their accustomed haunts and thereby defeat salutary segregation. So evident are the shortcomings of most of the control measures that some of the leading authorities on venereal diseases, both at home and abroad—I need only mention Neisser of Breslau and Blaschko[2] of Berlin (who have pursued with keen interest, under favored conditions, the work accomplished in this direction)—are exerting their powerful influence to oppose these measures because, from a personal disinterested and unselfish standpoint, regarding them as harmful, pernicious and inefficient. Valentine,[3] of New York, states that "the staunchest advocates of registration and periodic examination of prostitutes must admit that the dissemination of venereal diseases is thereby but feebly combated." In Paris, which has had a century of unsuccessful experience, the controlled prostitutes number only 4,700, and are rapidly diminishing in number, while the clandestines number conservatively 10,000, and are rapidly increasing. The brothels show the same proportionate decrease, and now scarcely aggregate 60, where formerly they numbered hundreds.

---

* Read before the Ohio State Medical Society, at Dayton, 1903.

[1] Weiss: THE JOURNAL A. M. A., Jan. 24, 1903.

During the past three years, Cincinnati has had another regime of prostitution control by the board of health, entailing regular registration, periodic examination, police surveillance, compulsory hospital treatment or a work-house sentence. Although these regulative measures have been carefully thought out and most rigidly enforced, I have personally failed, from an unselfish and disinterested standpoint, to note that our city has been materially benefited by these measures; on the contrary I can not but question whether they have not on occasions been conducive to direct pernicious harm. If they have been formulated for the purpose of preventing the spread of venereal diseases, as recently affirmed by those directly interested, my personal experience, both as regards private and hospital practice leads me to sincerely believe that, even in this direction, it has proved to be a signal failure. Unfortunately, owing to some recent changes, my clinical records do not permit me to quote statistics, but I am secure in my belief that venereal disease among this class of patients is of as frequent occurrence and exists in as aggravated form as was the case prior to these preventative innovations. Moreover, by far the larger number of clinical venereal cases, and I dare say almost exclusively, trace their origin to the non-controlled clandestine prostitutes. As regards private practice, my records show that out of 606 dermatologic and venereal cases, which came under my personal observation in 1900, 84, or 12.2 per cent. were gonorrheal, and 51, or 8.4 per cent. were syphilitic infections. In 1901, out of a total of 833 cases, 105, or 12.6 per cent. were gonorrheal, and 82, or 9.8 per cent., were syphilitic. In 1902, out of a total of 1,133 cases, 165, or 14.6 per cent. were gonorrheal, and 75, or 6.6 per cent. were syphilitic. For the first five months of 1903 (from January 1 to May 20, inclusive), out of a total of 768 cases, 125, or 16.1 per cent. were gonorrheal, and 67, or 8.7 per cent., were syphilitic infections; or the same ratio estimated for the entire year, would make out of a total of 1,843 cases, 300 cases of gonorrhea and 161 cases of syphilis.

| Dermatology and Venereal Diseases. Total Cases. | | Cases of Gonorrhea. | Cases of Syphilis. |
|---|---|---|---|
| 1900 | 606 | 84, or 12.2 per ct. | 51, or 8.4 per ct. |
| 1901 | 833 | 105, or 12.6 per ct. | 82, or 9.8 per ct. |
| 1902 | 1133 | 165, or 14.6 per ct.. | 75, or 6.6 per ct. |
| 1903* | 1843 | 300, or 16.1 per ct.. | 161, or 8.7 per ct. |

*Estimated for the year, from the records of the first five months, Jan. 1 to May 20, 1903.

From the foregoing table it can be readily seen that for the past four years, during which time a system of prostitution control has been inaugurated and carefully and systematically conducted in all of its details, the cases of gonorrhea in my private practice have steadily increased from 84 to 300 per year in number, or from 12.2 per cent. to 16.1 per cent. of the entire number of dermatologic cases, and the cases of syphilis, with slight variations, from 51 to 161 per year, and from 8.4 per cent. to 8.7 per cent. of all cases. The control, therefore, as at present exercised, is neither able to prevent a material increase in the total number of venereal cases, nor, what is more significant, to prevent proportionate increase in the per cent. over other forms of dermatologic disease.

I am frank to acknowledge that these figures, derived as they are from a strictly private practice, bear to themselves a sort of personal equation. They have been collated from records, gathered without reference to this particular phase of the question, in collaboration with Dr. Clarence A. Ihle. The number is sufficiently large to carry some weight and I am of the opinion that they represent a fair average of the prevalence of venereal diseases in private practice, under existing circumstances, in special reference to their increase or decrease. I am strengthened in this opinion by the impressions of some of my confrères, men who enjoy considerable venereal practice, who have personally stated to me that the results of a survey of their records do not materially differ from mine. The increase in number and percentage of venereal cases in my own practice is significant, when we take into account that, during the past four years, four cases out of five are dermatologic, that dermatology is my specialty, and that venereal diseases have been treated as a side specialty, for the most part as an integral and almost inseparable part of dermatology. In order to determine with greater accuracy and precision to what degree the spread of venereal diseases was prevented by the present system of control, the source of infection has been carefully traced in each individual case, as accurately as possible, for the past six or seven months, and recorded. If the control is as effective as its most ardent supporters would have us believe, relatively few cases could be traced to the individuals who are under the ban of medical registration and examination. My results showed that not relatively few, but on the contrary, a surprisingly large number could be traced to control prostitutes, 30 for the months of November and December, 1902, against 38 contracted from Cincinnati and its neighboring clandestines, and 7 from foreign sources. My records from Jan. 1 to May 20, 1903, are equally significant and, according to the following table, show 57 infections from control prostitutes against 69 of clandestine nature.

---

[2] Blaschko: Hygiene of Prostitution u. Venerischen, K., 1900.
[3] Valentine: N. Y. Med Record, Nov. 8, 1902.

Table, Jan. 1 to May 20, 1903.

| Source of Infection. | Gonorrhea. | Syphilis. | Ulcus Molle. | Condyloma Acuminata. | Total. |
|---|---|---|---|---|---|
| Cincinnati clandestines. . | 49 | 19 | . . . . | 1 | 69 |
| " exam. prostitutes | 43 | 8 | 4 | 2 | 57 |
| Foreign sources. . . . . . . . | 10 | 10 | 2 | . . . . . . . . | 22 |
| Innocent infections. . . . . | 1 | 8 | . . . . | . . . . . . . . | 9 |
| Record unobtainable.. . . . | 22 | 22 | . . . . | . . . . . . . . | 44 |
| Total . . . . . . . . . . . . | 125 | 67 | 6 | 3 | 201 |

Total of all dermatologic and venereal cases, 768.

From the foregoing it can be readily inferred that the control, as at present exercised, is not a very effective one, that most of the cases are contracted, even in private practice, outside its pale, and that the regimen exercised over control prostitutes, however rigid or carefully carried out, does not render them non-infectious in character.

If the system was simply ineffectual and powerless to show positive results I, for one, would not endeavor to criticise it unfavorably or invoke its just condemnation. Sincere as is my belief, from a thoroughly disinterested and unselfish standpoint, that it is powerless and impotent to materially prevent the spread of venereal diseases, I am doubly assured that its influences in other directions are decidedly pernicious and that it effects material harm.

Control with periodic examination gives to the laity a false sense of security. There is no more powerful conservator of social purity, I believe, than the fear of impending danger to the transgressor, the fear of contracting a venereal disease; this fear is materially minimized by the assurance of the periodic examinations made for the purpose of determining the abscence of infectious diseases. This assurance is increased in Cincinnati by the issuance of a diploma-like certificate, which "must be exhibited conspicuously in the room occupied by the person to whom it is issued." Though clearly evident that this practice is alluring and attractive to the inexperienced and uninitiated, it suffices to state that it is an experience common to many practitioners, to meet infected patients who, under the guise of this false security, have indulged in an intercourse from which they otherwise would have abstained, or in which they would have otherwise used measures to prevent infection. That the issuance of these certificates is pure deception and fraud, is evident from the innumerable infections which can be traced to the possessors, 87 cases occurring in my own practice in seven months' time.

It is generally conceded by most authorities, Blaschko,[4] Jadassohn, Neisser and others, that one-half to one-third of the prostitutes, even in control cities, are constantly infected with gonorrhea, and that at least 80 per cent. of them are infected with syphilis during their first year in that life. Havas[5] states that after the gonococcus has passed the cervix and reaches the adnexa, the disease is incurable and the prostitute becomes a source of constant infection. In the light of these facts, it is certainly farcical, I may dare say criminal, to grant this highly contagious class of individuals a certificate, with the injunction that it be prominently displayed, reading that "We have made careful examination of said —— and find her free from any venereal or contagious disease."

If these certificates were issued only to prostitutes living in public houses or alone, and more or less clandestinely pursuing their calling, though seemingly uncalled for and unjustified by clinical experience, it would be more pardonable than the much graver offense of granting them to masseuses, manicure artists, etc., who, under the guise of an affected calling, are licensed to practice prostitution without fear or restraint, and under the cloak of this deception to advertise it in the daily press and thereby virtually place an additional premium on vice. A large quota of recent infections, in my practice, have been contracted in a certain massage and manicuring establishment, whose advertisement appears almost daily and whose inmates are regularly examined and are given their certificates, and this control, in Cincinnati, we are assured is practiced solely for the purpose of preventing the spread of venereal diseases.

But the sacrifice of the many unsuspecting and falsely assured innocents on the alluring altar of venereal disease is not the only harm that can be attributed to control. The power which it exercises over these unfortunates becomes almost absolute, and one from which there can be no appeal. It can and often does usurp constitutional rights, restrict liberty, infringe personal privileges, make hospital treatment compulsory, or even impose a work-house sentence. These conditions not only pave the way for an uncalled-for interference, and create opportunities for blackmail and personal gain, but, by rendering the position unduly hard, tend to materially diminish the number of controls and to increase the more numerous and more dangerous clandestines. The fear of the penalties which may be imposed, compulsory hospital treatment, etc., often impels these individuals to conceal from their examiner the various forms of venereal lesions (mucous placques, condylomata lata, gonorrhea, etc.), to which, if his work is at all effective, his attention should be particularly directed. Formerly they took an interest in bringing these lesions to the attention of their private physician, but of late the fear that this knowledge may reach the ears of the examiner and incur his displeasure, removes them also from this attention.

There can be no question but that exercise of power occasionally has been very much abused in Cincinnati. An example was the suicide of a beautiful young girl of respected parentage who died within the past year at the City Hospital because she had been threatened with arrest and prosecution at the hands of an influential citizen whose displeasure she had unfortunately incurred. A striking example, illustrating to what excesses such an elastic system of blackmail can be carried, occurred in my presence in one of the control wards of the City Hospital. One of the unfortunates who had apparently served out her full quota of time and imagined that she was sufficiently free from her ailments to merit her just release, addressed the controlling staff officer by asking, "Say, you, when are you going to let me out?" I am sure that the unfortunate one never intended the remark to be uncivil or disrespectful, but the autocratic staff officer, who, incidentally, is one of the most active participants and ardent advocates of prostitution control, replied: "What, you say 'you' to me; I'll teach you better; you will stay four weeks for that." The Czar of Russia could not have exercised over his own subjects more absolute or arbitrary control, and her injured feelings, restricted liberty and infringed rights took vent in a flood of tears. Instances of this character could be multiplied almost indefinitely. Individuals belonging to this class are almost daily subjected to the indignities of arrest and persecution, on the illegal charge of loitering, and if not illegally confined in a hospital or prison, suffer infringement of private rights and restrictions of personal liberty. It frequently happens that these individuals, when illegally confined, will buy their personal freedom and liberty at the price of a marriage compact, which is the equivalent of making a hollow mockery of one of the most solemn, holy and impressive ceremonies of our higher, enlightened civilization.

---

[4] Blaschko: Berlin klin. woch., 1892, 5.

[5] Havas: Monatsh. f. Prak. Derm., xxxiii, p. 144.

We will credit the officers who exercise the present prerogatives of control in Cincinnati with being honorable, conscientious and upright, although somewhat blind in their supreme faith in their personal efforts. The facilities for exercising an unfair interference and for secretly extorting blackmail in return for protection are so pronounced that, if perchance control were exercised by officers who were unscrupulous or dishonest, they could rapidly and successfully inaugurate a foul and degraded system of corruption. I am informed that these individuals, even under the present system, are in such moral dread of an unfair discrimination or an unjust interference, that they seek medical attention only from the regular examining physicians, and are timid in seeking attention elsewhere, however desirable in character, for fear that such information may reach the ears of the examiner and incur his displeasure. This influence is decidedly pernicious, because any measure which tends to discourage medical attention only tends to promote the spread of venereal diseases. This same moral fear of the examiner and the compulsory treatment he is able to impose also prompts these individuals to discourage every form of medical attention and to hide any knowledge which would lead to the discovery of any form of venereal infection, to lavage freely immediately prior to each examination and to conceal venereal lesions of every infectious form. As long as the prostitute looks on the examiner, not as a physician and benefactor, but as her persecutor and prosecutor, so long will any measure for the exercise of a successful control and prevention of the spread of venereal diseases defeat the very object it seeks to attain. Medical service to this class of patients should be freely given and should be the very best that can be given; it should not be imposed combined with compulsory hospital treatment at $1 per day. In order that these unfortunates should be encouraged to freely seek proper attention it should be given with all the privacy and refined and delicate detail that is awarded to the treatment of these cases in careful private practice, not by officials wearing the badge of supreme authority, but by those having nothing else to recommend them except their painstaking, conscientious efforts and their personal attainments, as able, successful and efficient physicians.

The present Cincinnati health officer and official head of the prostitution control stated recently that the 500 regularly weekly examined prostitutes constituted three-fourths of the source of infection of venereal disease. I do not know the source of his information, but personal knowledge of the self-supporting industrial female life in Cincinnati, of the large number of dependent females employed in our numerous factories, of the unhealthful moral atmosphere in which they work and live, of the close association of the sexes in the work-room, of their love for luxury and personal extravagance, not commensurate with their usually moderate income, leads me to believe that the clandestines number at least 10,000 and, granting that the control prostitutes average five or even ten callers a day, that they by no means constitute the greater source of infection. The fact that sixty-nine cases of venereal disease were contracted in five months from Cincinnati clandestines, against fifty-seven from control sources, in a private practice, speaks for itself, that the greater source of infection is from the clandestines, especially when we consider that these infections occurred for the most part among a well-to-do class who can easily afford the relative greater expense incurred in control indulgence. In the more numerous indigent, and for the most part laboring class of individuals, the proportion of the clandestine infections greatly predominate, and in clinical practice it is almost the exclusive form of infection.

We have now considered the inefficacy of the present control, its harmful and pernicious influences and the dangers which may attend its unscrupulous administration; we will now consider briefly a few additional measures, which, if properly conceived and consistently carried out would, I believe, innure to the prevention of the spread of venereal diseases. First and foremost is, I believe, a thorough education of our youth—which should become an integral part of their general schooling and training—as to the dangers that attend improper relations; that continence and abstinence are strictly compatible with the best of health and well-being; that in case they should feel unable to properly restrain their inordinate passions—and I state this with some reservation as applying particularly to those individuals and practitioners who believe that inordinate passions must be sexually gratified and whose watch-word rests in the unsuppressible and uncontrollable character of prostitution—indulgence should be sought only from proper sources, in which event they should be given the best form of instruction in regard to self-protection.

When we consider the numerous causes which predispose to prostitution, one of the most potent factors, not even second to the assurance of freedom from the danger of contracting venereal disease, is a sense of security against subsequent conception and parturition and the resulting publicity and social disgrace. This feature is so alarmingly prevalent in Cincinnati that a wholesome fear in this direction no longer exists, and a great incentive is thereby given countless individuals to take the initial step that invariably leads to remorse and despair and often to degradation, disease, abject misery and an early death. Abortion is practiced with such license and freedom that there are men who have gained, among the masses, special reputations in this field of work, so that their names, in this connection, are almost household words. Some of them occupy prominent offices in our high-class office buildings, and it is not an uncommon experience to find patients astray in the wrong office inquiring for "the doctor in the building who does that kind of work." I am sure that if the health department had exercised one-fourth the effort expended in controlling prostitution in correcting this flagrant and nefarious malfeasance, it would have rendered a ten times more grateful and actual service, and at the same time would have exercised a more genuine control, that would have in due course of time prevented in greater measure the spread of venereal diseases.

There are a number of more legitimate and far more productive fields for the exercise of measures for the prevention of the spread of venereal diseases than the exercise of a doubtful and oppressive control over prostitution. Aside from the proper education of our youth, the instruction in individual prophylaxis, and a control over licentious abortion, regulative measures should be adopted, inquiring into the self-supporting character of female industrial life, the close association of the sexes in the work-room, the immoral atmosphere in which they work and live, remuneration commensurate to a degree with proper living and being, enactment of legislation for the salutary segregation of public and clandestine prostitutes, and its enforcement within bounds of propriety, justice and reason. It should abolish common drinking cups and utensils and promote education along the lines of phophylaxis in regard to the dangerously unclean dental, manicure, chiropodist and surgical instruments, and the prolonged infectious character of venereal diseases.

Time and space do not permit me to give to these and many other measures (for example, the establishment of homes for the tempted and fallen), the attention they justly deserve, inasmuch as they are somewhat foreign to the subject of the control of prostitution in reference to the spread of venereal diseases, they scarcely merit special consideration in this paper.

A few quotations, recently gleaned from some of our leading specialists, relative to the subject will not, I trust, be out of place at this juncture. Stelwagon[6] of Philadelphia states: "We will never make headway in the control of venereal diseases by legalizing prostitution or recognizing it as a legitimate calling." Gottheil[6] of New York says: "Municipal regulation, as practiced in many of the European cities, is neither successful or desirable." E. L. Cocks[6] of New York says: "A streak of over-conscientiousness and trying to do something—and the result has been that prostitution, which was confined to the tenderloin, has been scattered all over the city. Under the new order of things, prostitutes are now our neighbors."

To briefly recapitulate, suppression of prostitution is impossible, and control is impractical; it is absolutely incapable of coping with the larger and more dangerous class of clandestines, and it is powerless and impotent to materially prevent the spread of venereal diseases, emanating from those directly under control. Its influences are decidedly pernicious and harmful, inasmuch as it defeats salutary segregation, increases the more dangerous class of clandestines, restricts liberty and infringes on personal and constitutional rights. It legalizes crime and fosters disease and immorality by imparting a false sense of security, and is virtually a deception and a snare. It creates opportunities for blackmail and personal gain, brooks an unjust and often unendurable interference, and discourages necessary and salutary medical attention. There are far more rational and legitimate measures for the prevention of the spread of venereal diseases, along the lines of the suppression of abortionists and the inculcation of general and individual education and prophylaxis.

## Clinical Reports.

### A CASE OF ANGINA AND DYSPHAGIA,

ILLUSTRATING THE VALUE OF ANTISYPHILITIC TREATMENT IN A CONDITION MISTAKEN FOR EPITHELIOMA.[*]

FRANK WOODBURY, M.D.
Formerly Adjunct Professor of Laryngology in the Philadelphia Polyclinic and School for Graduates.
PHILADELPHIA.

*History.*—Mrs. X., a widow, about 35 years of age. Her husband died of pulmonary tuberculosis about 18 months before I saw her. She nursed him during his illness, and in consequence of much loss of rest, and of the great physical and mental strain, her health had been much impaired. In the year following, however, she had apparently regained her health and strength. She was a brunette, well nourished, and physically well developed, of a bilious temperament and of active habits. The account of her ailment, for which she sought the advice of the late Dr. Thomas G. Morton, was that for the last six months she had experienced great pain in swallowing, even on the attempt to drink a little milk or water. Otherwise her health had been good. She thought that she had lost a few pounds in weight, which she attributed to her inability to take nourishment. She located the pain principally on the right side of the throat, in the pharynx. There had been no change sufficiently marked for her to notice it for several months, except that the pain had become more severe. She had been under medical treatment for the preceding six months, without relief, and her physician had referred her to Dr. Morton for surgical treatment, stating that she had epithelioma of the throat. She was willing to submit to an operation if necessary.

*Examination.*—At Dr. Morton's request, I examined the patient at his office and saw her there several times subsequently. On inspection, I found an area of passive hyperemia involving the right tonsillar region, the anterior and posterior pillars of the pharynx, and extending a little on to the soft palate; the tissues were slightly swollen, but the surface was clean and not ulcerated. The appearance was that of an ordinary crescent inflammation, except that the color was a deeper red, and the tonsil itself was not enlarged. On digital examination I did not detect abnormal hardness. The touch of my finger caused a paroxysm of agonizing pain, lasting several minutes. There was some tenderness externally, under the angle of the jaw, but no glandular involvement could be detected. The postcervical and epitrochlear glands and those on the mastoid eminences showed no marked evidence of disease; although a few could be felt and moved under the examining finger, they were not hard, tender, nor much increased in size.

*Diagnosis.*—Three possibilities suggested themselves, viz.: epithelioma, tuberculosis, and syphilis. From the absence of glandular involvement, we might also include sarcoma, but it did not seem possible that in six months' time such a tumor could have made so little progress and the general health have suffered so little impairment. The diagnosis of epithelioma, which she had brought with her, demanded more deliberate consideration. It had been made by a physician who had studied the case for months. The long duration and comparatively slight development of the lesion would exclude epithelioma, were it not for the fact that the malignancy might have been a comparatively recent development, possibly as the result of too vigorous treatment with caustics or irritants. Opposed to the view of cancer was the appearance of the lesion, the absence of infiltration, and particularly the apparently normal condition of the submaxillary lymphatic glands. Moreover, there was no appearance of cachexia whatever.

In favor of tuberculosis of the throat were: 1, The history of nursing a husband who had died of phthisis; 2, the chronic nature of the lesion, which had refused to heal under medical treatment; 3, the age of the patient and her bereaved condition. Opposed to this diagnosis were the facts that: 1. The lesion was not ulcerated; 2, the lungs were normal, and, 3, there was no evidence of constitutional symptoms, although the disease had existed for so long a time.

We were driven to the hypothesis of syphilis, although the evidence in its favor was of the most intangible character. To the usual queries as to history of eruption on the skin, bone pains, loss of hair, sores in the mouth or elsewhere, negative replies were given. The circumstances did not admit of a close examination for the stigmata of syphilis—apart from the condition of the lymphatics of the neck and arms, which was not at all conclusive. Taking into consideration her appearance of general good health, her social condition, and the clinical maxim that "no condition in life absolutely excludes the possibility of syphilis," we decided to proceed to the test of a therapeutic diagnosis, as but little time would be lost in case it should prove to be malignant, and the treatment would afford some relief to the symptoms, in either event. Whether the lesion might be primary, secondary, or tertiary, could not be decided positively in the entire absence of any history of infection. But the absence of enlarged glands under the jaw, and the extreme painfulness of the lesion, were in favor of a late manifestation. There were no constitutional symptoms, skin eruption or mucous patches in the mouth, as we might expect in the secondary stage, so we concluded that the lesion was probably gummatous, although its color, and the fact that it had not ulcerated, could not be reconciled very closely with this view.

---

[6] The Journal A. M. A., Jan. 24, 1903.

[*] Read before the Section on Otology and Laryngology, College of Physicians, Philadelphia, 1903.

*Treatment.*—The line of treatment decided on was as follows:

| | | | |
|---|---|---|---|
| ℞. | Hydrargyri iodidi flavi | gr. 1/3 | 02 |
| | Ext. gentianæ | gr. ii | 12 |
| | Ext. hyoscyami | gr. 1/4 | 015 |

M. et ft. pill No. i, gelatin coated. Sig.: Take one pill three times daily after meals.

She was also given the following:

| | | | |
|---|---|---|---|
| ℞. | Potassii chloratis | ʒii | 8 |
| | Ext. rhois glabræ | ʒvi | 24 |
| | Glycerini | ℥ss | 15 |
| | Aq. rosæ q. s. ad | ℥vi | 180 |

M. Sig.: Dilute with two parts hot water and use frequently as a mouth wash and gargle.

To relieve the extreme hyperesthesia of the throat, she was given ten-grain doses of potassium bromid, three or four times a day for a few days. She was directed to eat four eggs a day and to drink two quarts of milk, in addition to broth, breakfast cocoa and *café au lait*. The local treatment consisted in the application of a forty-grain solution of nitrate of silver to the affected area, about once a week.

*Results.*—Three days after the first consultation, she presented herself and reported very great improvement. Her throat looked better and the pain on swallowing liquids was almost gone. In the course of five weeks she had entirely recovered. As a matter of precaution, she was advised to continue a mixed treatment for several months longer, with occasional intermissions of a week. As she has not returned for further treatment, I conclude that she is still enjoying excellent health.

*Comments.*—Cases of syphilis of the throat are sufficiently common to be allowed to pass without comment; the only points deserving of notice in the present case are the long duration without ulceration, the extreme dysphagia, and the very prompt response to the treatment pursued. It is also an illustration of the diminishing value of a history of the primary infection with syphilis, in making up the diagnosis. Cases of syphilis insontium are not rare, and, in view of the facility with which the virus may be communicated by kissing, by the use of public drinking cups, by unclean dental instruments, etc., it is a matter of wonder that they are not vastly more common than they are.

# STRYCHNIN POISONING BY INHALATION.

MINERVA M. NEWBECKER, M.D.
ORD, NEB.

*History.*—May 31, 1903, I received a hurried call to visit a man in the country who had been poisoned by strychnin. I found the patient wrapped in comforters, and propped up in an easy chair. He appeared to be well nourished, was 30 years old, and had never been sick a day in his life. He was very nervous and greatly prostrated. His heart was beating at about 88 per minute and very irregularly, and had a decided tremor. His tongue was coated and trembling, and somewhat moist; his eyes were suffused and the conjunctivæ injected; the muscles about the mouth were retracted, showing his teeth and giving to his face the "risus sardonicus."

*Etiology.*—I was given the following history: Two days previously he was preparing a mixture to poison rats. It consisted of some corn, mixed with strychnin powder, over which he poured hot water, stirring it thoroughly with a stick. The water was not boiling, but was hot enough to rise in steam; this he inhaled while bending over the mixture. While he was working thus he had a feeling of chilliness, and a numbness crept over him, followed or accompanied by a tingling in his hands, which soon extended all over his body. Then he felt muscular twitchings and jerkings resembling spasms, and lightning flashes which began with his hands and extended up his arms to his face and spine, and finally involved the whole body. There was no opisthotonous or loss of consciousness, but an intense anxiety and fear of impending death. The jaws felt stiff, the secretions were arrested, the tongue was dry and cracked, and the urine suppressed. The severity of the attack lasted about an hour.

*Treatment.*—Various remedies were administered by his friends. They tried to cause emesis with warm water and mustard, but failed; then they gave him cathartics, and finally resorted to melted lard. He soon experienced relief, and took the lard with avidity, continuing to do so at intervals all night. He slept none, but felt better in the morning. The bowels moved freely from the cathartic, and the flow of urine was copious. During the forenoon he had another attack, but milder than the first, and still another in the afternoon. The lard treatment was resumed, and again gave relief. He slept none the second night, and kept the lard can beside his bed, eating it cold when he felt the numbness coming on, which occurred once or twice during the night. About noon he found himself growing worse, and sent for a physician. As I found him weak and trembling, with the temporal arteries hard and prominent, and still suffering from too great arterial tension, I gave him five or six drops of Norwood's tincture of veratrum viride, and he soon became easier. I left some potassium bromid and chloral, to be given at night and whenever he felt the spasms coming on; also antispasmodics and stimulants to be given during the intervals, and castor oil to take the place of the lard, and recommended that he be kept quiet in bed and allowed to sleep.

*Course.*—Three days later, being called again, I found him sitting up, evidently much improved. He was having a slight spasm once a day. Some hours before these spasms would begin he was unable to urinate, a few drops only passing away at a time; but when the spasm was over he passed about two quarts at one time. He had no desire to urinate until after the attack. He had no feeling in the genito-urinary organs; they seemed to be involved in the general anesthesia. He sweated profusely in the intervals of relaxation, and to further stimulate the skin and assist elimination I recommended a warm sponge bath to be given at night, and attention to the excretions of kidneys and bowels. I prescribed enough bromid and chloral to insure good rest, to be withdrawn as the nervousness and insomnia passed away. Beside this, a general tonic was given. Some two weeks later the patient called at the office. He was still nervous, and occasionally felt slight jerkings and twitchings, but had no pronounced spasms and was slowly regaining his strength. To my question as to whether he might not have conveyed some of the powder to his mouth by his hands, he answered in the negative; he was sure no powder adhered to his hands.

*Comments.*—This case was interesting to me, as the liability to strychnin poisoning by inhalation had never been brought to my attention, and I do not find the subject treated of in any books at my command, though, from the extreme solubility of the drug, such liability may be a well-known fact. While the alkaloid, strychnin, is difficultly soluble, the sulphate, presumably the salt used, is very soluble, being 1 part to 10. The vapor, carrying in solution a small amount of the salt, comes in contact with the moist surface of the mucous membrane of the nose and mouth, is readily absorbed and carried into the circulation, some of it, no doubt, being swallowed, and entering the portal circulation from the stomach. Strychnin is rapidly absorbed into the system, and very slowly excreted, most by the kidneys, then by the mucous and cutaneous surfaces. This emphasizes one point to be observed in the treatment: that is to draw off the urine to prevent accumulation in the bladder, which admits of reabsorption of the poison held in solution, and its return to the circulation, thus exerting its deleterious influences on the system again and again. Strychnin, like digitalin, diminishes the secretion of urine by causing powerful contraction of the renal vessels, and a large dose may completely arrest its secretion, and probably also the circulation through the kidneys. There was a question in my mind, however, whether the urine in this case was really suppressed, or whether the bladder was full to overflowing, and a little dribbled away, from lack of sensation. Patient claimed that he had no feeling in those organs, before and during the spasms, but as soon as they were over, leaving him in a relaxed and weakened condition, the urine flowed freely, and was passed in large quantities.

I should be glad to learn whether this means of strychnin poisoning has been observed. It seems improbable to me that a sufficient amount of the poison could have been swallowed from the secretions of nose and mouth to cause such serious symptoms.

## A CASE OF DIPHTHERIA AT SEVENTY-SIX YEARS OF AGE.

A. BELCHAM KEYES, M.D.
Professor of Gynecology, Chicago Policlinic; Instructor in Rush Medical College.
CHICAGO.

*History.*—Some time ago I was called to see P. D., aged 76, who complained of a slight indisposition and of having had on the previous day a slight stiffness of the neck, from which he had recovered before my visit.

*Examination.*—The pulse was 82 and temperature 99 F., condition of vascular system somewhat arteriosclerotic, heart, lungs and urine negative. On the right leg was a varicose ulcer about the size of a silver dollar.

I examined the throat in a routine way, and found on the left anterior pillar a small, oval-shaped, whitish-gray patch about half the diameter of a dime, and laughingly remarked that the patient was getting the children's diseases over again, and promised to return later and make a culture before prescribing any antiseptic gargle or spray so as not to interfere with the growth on the culture media.

*Diagnosis.*—Two hours later I inoculated two of our small health department culture boxes from the patch and in due course stained and examined, finding a pure culture of Klebs-Loeffler bacilli.

*Treatment.*—The culture was submitted to Drs. Adolph Gehrmann and R. B. Preble, with a request to the latter to inject antitoxin, 2,000 units being injected without apparent baneful influence on the system in any way. At the same time a three-year-old grandson who had arrived at the house that day on a visit was injected with 1,000 units. Beside isolation, I prescribed antiseptic gargles, both as a curative and a prophylactic measure, to lessen the chance of the spreading of the disease among the rest of the family.

*Course.*—The case apparently ran its course absolutely without symptoms, the patient to this day refusing to believe the true nature of the disease, because at no time was there the slightest indisposition after the first day. A fresh culture four days after the first was forwarded to the health department and again a confirmatory diagnosis was made microscopically.

*Comments.*—The peculiar feature remarked on the senile atrophied mucosa was the absence of any sign of either a tendency to spread or to shedding of the pseudomembrane for about ten days, until I at last had it swabbed several times a day with tincture of iodin. Some time later the leg ulcer also healed almost entirely.

The patient is now in good health. The child did not contract the disease. I report the case because of the extreme age of the patient, and to show the necessity of making a culture in all cases of throat disease, no matter what the age of any suspected case of diphtheria may be, also to show the probability of its dissemination by adults of all ages in whom the disease may fail to cause symptoms.

## New Instrument.

### A NEW INTRAGASTRIC BAG.

J. RAWSON PENNINGTON, M.D.
CHICAGO.

The value of the intragastric bag in the treatment of many forms of stomach and intestinal diseases is no longer questioned. There are many bags on the market, but none of them is constructed so that a definite relation can be maintained between the distal end of the stomach tube and the bag. The consequence is that the free end of the tube frequently curls up and catches in the side of the bag, which is not only disagreeable to the patient, but often ruptures the bag in withdrawing the tube from the stomach.

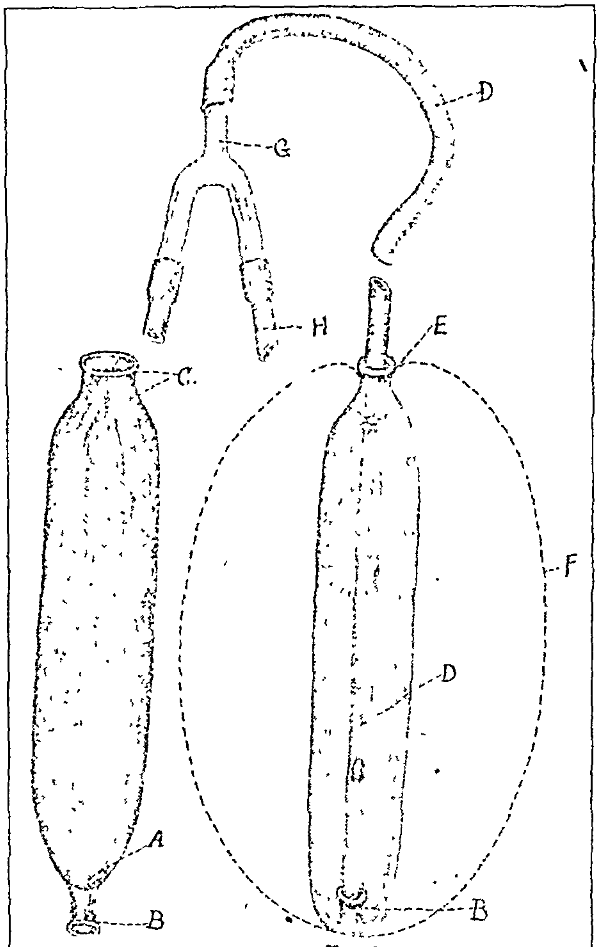

Fig I   Fig II.

The bag shown in Figures 1 and 2 is made of extra fine rubber tissue, and is so constructed as to overcome these objections. To the distal end of the bag is vulcanized a small tube, AB, which fits snugly over the distal end of the stomach tube, D, and is made secure by a ligature. The bag is then pulled over the tube, D, and secured by another ligature, E. Both ends of the bag now being tied to the tube, they maintain a definite relation to the tube and to each other, whether the bag is empty or distended. G is a Y-shaped glass tube inserted into the tube D. Over the arms of this Y-shaped tube two rubber tubes, H, are fitted, acting as inlet and outlet tubes, with stopcock attachments, enabling one to use a single stomach tube for the same purpose that a double tube is used. The bag can be used with either the open or closed end, single or double stomach tube.

## NERVE FIBERS AS PATHWAYS FOR TOXINS, AND THE TREATMENT OF TETANUS.

A short time ago we called attention to the significant experiments of Meltzer, who found that if a nerve is ligated in one point and the animal injected with methylene blue, the nerve becomes stained throughout, but that if the nerve is ligated in two places the intervening portion remains unstained. From this it may be inferred that whatever fluids enter the neurons, whether food or poison, enter from the extremities of the neurons and not from the blood vessels coursing along the nerve. It must be, therefore, that there is a continuous streaming within the substance of the axis cylinders, perhaps allied to the streaming of the protoplasm that occurs in the cells of certain plants and lower animals, by which means substances may be transported along the axis cylinders. As the myelin sheath seems to be a rather impervious structure, it may explain the failure of substances in the vessels of the nerve trunk to enter the axis cylinder along their course. This novel condition of circulation within the nerve fibers may be expected to throw more or less light on some of the nervous diseases, and we at once think of two to which this particularly applies—tetanus and rabies. It so happens that this work of Meltzer's fits most beautifully with the most recent observations in regard to tetanus. As these appear to be of practical value in suggesting a more hopeful method of treatment of tetanus, we shall endeavor to explain them briefly.

In laboratory animals with tetanus, whether resulting from inoculation of bacilli or toxins, the first and most severe manifestations appear in the muscles near the region of the inoculation. This localization is not usual in man, for, irrespective of the site of injury, the earliest effect is usually in the muscles of mastication, yet occasionally it happens that the spasms first develop in the injured part, as they do in animals, and still more often it may be noticed that the injured area is more affected than the rest of the body. Particularly to be mentioned is the "head tetanus" following wounds of the face and head, oftenest in the course of the fifth cranial nerve, which is followed only by local spasms, often limited to the injured side of the head. Because of this peculiarity, it has been thought that the nerves rather than the blood vessels were the carriers of the poison to the cord, thus explaining the localized results. Indeed, during a certain period in the history of the pathology of tetanus it was sought to treat tetanus by excising part of the nerve supplying the injured area, because the spasms were thought to be due to exaggerated reflexes resulting from irritation of the endings of the nerve.

Antedating Meltzer's publication, Meyer and Ransom[1] have obtained by careful experiments results that indicate what Meltzer proved, that the peripheral nerves may carry substances within their axis cylinders toward and into the spinal cord. According to their results, tetanus toxin reaches the ganglion cells of the cord solely by passing along the axis cylinder processes. None whatever reaches the ganglion cells through either the blood stream or the lymph stream. Apparently the point of entrance is in the terminals of the motor nerves, where they are devoid of the myelin sheath, and the sensory nerves seem entirely unable to carry toxins from the periphery to the center. Injection of tetanus toxin into the sensory roots caused only increased pain reflexes, but none of the characteristic muscle spasms. Furthermore, the poison seems to diffuse upward in the cord, for if the spinal cord of an animal inoculated in the hind leg was severed the tetanus was limited to the posterior portion of the body. It has always been considered rather remarkable that tetanus toxin required so long a period of incubation after injection, acting less like a ready-formed poison than like an infection; for this many explanatory theories have been advanced. Now it would seem that the greater part, if not all, of this incubation period is occupied by the passing of the poison from the periphery to the cord, for if the poison is injected directly into the cord in animals the symptoms appear at once, without the usual delay of hours or days.

In tetanus, therefore, it seems that the poison reaching the cord through the motor axones produces a hyperexcitability in their ganglion cells; so that they respond over-much to slight stimuli, such as are continually brought by the afferent fibers, and which, normally resulting in muscle tone, in this case cause tetanus. Within the cord the excessive poison is spread further until the cord is more or less completely affected, with consequent reflex hyperexcitability and its results. If the poison enters the blood stream it then reaches all motor endings in small quantities, and being by them transported to the cord results in generalized instability. When the tetanus is thus diffused in different animals, different anatomic regions are found to be most susceptible, and in man this seems to be the region of the fifth nerve.

The inefficiency of antitoxin in the curative treatment of tetanus seems to be due to its failure to follow the toxin along the nerve fibers, and hence it does not reach the toxin that is doing the harm. Toxin in the blood, lymph and tissues antitoxin can neutralize and thus lessen subsequent effects, but that which has entered the nerve it can not reach. For example, a rabbit very highly immunized against tetanus toxin so that two drops of its blood contained sufficient antitoxin to neutralize a certain toxic dose, was killed almost as if non-immune when this dose was introduced into the substance of a nerve. The therapeutic conclusion, therefore, is that antitoxin injected subcutaneously in the usual way can neutralize toxin that has not yet entered the nerves, and if administered in sufficient quantity before a fatal dose is absorbed it will prevent death. But if too large a quantity has entered the nerves no amount of antitoxin will check the disease. However, a possible way of reaching the toxin is suggested by these experiments, namely, to inject the antitoxin directly into a large nerve, preferably the one supplying the injured part. This has been done in one case with encouraging results. A man received a large dose of antitoxin after the development of a wound infection, in spite of which eight days later there developed a local, apparently progressive, tetanus. Antitoxin was then injected into the nerve trunk of the injured arm and the symptoms soon disappeared, complete recovery resulting. To be sure, one case of tetanus does not indicate very much, but at least we have offered another possible way of administering antitoxin that may be the long-sought one. There is no doubt that, with the great potential possibilities that lie in tetanus antitoxin, as shown by its very active neutralization of free toxin, there should be some way of getting better results than have been obtained so far. It is to be hoped that the intraneural route will be given the thorough trial it deserves in view of the futility of all other methods of administering antitoxin, except, perhaps, the intraspinal method advocated in this country by Luckett,[2] which is also in the experimental stage.

## ALKAPTONURIA.

The characteristics of the urine in alkaptonuria, a condition first described by Boedeker in 1859, are briefly as follows: When voided it has a normal appearance, but rapidly acquires a deep-brown color and ultimately becomes black on exposure to the air. The brown color is greatly intensified by alkalies, its development being accompanied by the absorption of oxygen. The urine reduces Fehling's solution with the aid of heat, the mixture at first being of an inky-black color. It reduces ammoniacal silver-nitrate solutions in the cold. The bismuth test for sugar yields negative results. The urine does not ferment, and it is inactive to polarized rays. Ferric chlorid solution produces a transitory bluish-green color. Linen moistened with the urine turns a deep-brown color on exposure to the air.

The condition is congenital in the vast majority, if not all, of the cases. In a good many cases a history was obtained that the individual's urine in infancy stained the napkins a dark-brown color. Alkaptonuria persists throughout life. That it is rare is demonstrated by the fact that A. E. Garrod states that only 40 cases had been reported up to 1902. Four of these were reported from the United States. It predominates in males. Of the 40 cases, 29 were males and 11 females. The anomaly is likely to make its appearance in two or more brothers and sisters whose parents are normal, and among whose forefathers there is no record of its having occurred. There is only one recorded instance of alkaptonuria having been transmitted from an affected parent to a descendant. This was from a father to a son, and occurred in one of the American cases.

Although Boedeker gave the name "alkapton" to the substance producing the interesting urinary changes characterizing this anomaly, it remained for Baumann and Wolkow, in 1891, to demonstrate that they were due to the presence of homogentisic acid (Homogentisinsäure, $C_8H_8O_4$). This acid has been found in practically all the cases reported subsequent to that date and in the urine of some of the cases previously reported, and is now conceded by all observers to be the cause of the condition. Lead homogentisate is easily obtained by heating the urine nearly to the boiling point and adding five or six grams of neutral lead acetate to each 100 c.c. of urine and allowing it to cool for twenty-four hours. The lead salt crystallizes out in the form of brownish stellar-shaped acicular crystals, watery solutions of which give all the reactions of the original urine. Baumann, Wolkow and Embden believe that the homogentisic acid is derived from tyrosin. They have shown that when tyrosin is fed by mouth to an alkaptonuric nearly the whole of it is excreted as homogentisic acid, although the acid is not excreted in the urine when tyrosin is ingested by a healthy person. Beyond the fact that tyrosin and homogentisic acid are both aromatic acids, the two have nothing in common, and the conversion of the former into the latter involves a shifting of the hydroxyl groups on the benzene ring; in other words, a simultaneous oxidation and reduction within the molecule. Baumann and Wolkow believed that this conversion was due to bacterial activity in the intestinal canal, and suggested that there might be a specific bacterium in such cases. There is no definite experimental evidence to support this view.

A. E. Garrod, who has been much interested in the subject, has probably offered the true explanation of this curious anomaly. As a result of his investigation he finds that a very large percentage of the cases, concerning which he has been able to collect data, occurred in individuals who are the offspring of the marriage of first cousins who do not themselves manifest the peculiarity. He points out that in this respect it resembles albinism and possibly also cystinuria. He has advanced the view that alkaptonuria is a "sport" or alternative mode of metabolism, congenital in origin and persistent throughout life. In favor of this view is the fact that each individual excretes from day to day a very constant amount of the hemogentisic acid, the variations being within narrow limits and easily explained by fluctuations in the amount of proteid food taken from day to day. The average daily excretion of the acid has ranged between 2.6 grams in a child three and one-half years old and 5.9 grams in a young man of eighteen. One would reason, therefore, that alkaptonurics suffer from some inherited metabolic defect, and it seems probable that this defect is closely related to the metabolism of tyrosin.

### SYPHILIS IN ANTHROPOIDS.

In a former number[1] we noted editorially the reported success of Metschnikoff in infecting the chimpanzee with syphilis. Recently Metschnikoff and Roux[2] have given a concise statement of their observations, which are most interesting and which may be of importance in furthering the study of syphilis.

The first chimpanzee, a female, was infected with "syphilitic virus." After twenty-five days a hard sore developed, which Fournier and others were willing to consider of syphilitic nature. A month later about fifteen papules appeared on various parts of the body, and remained until the death of the animal, which occurred fourteen weeks after the inoculation was made. A pneumococcus was cultivated from the heart's blood, and it is supposed this organism gained entrance through a gingivitis and caused death. Before the animal died, however, a second chimpanzee was inoculated on the penis from the now subsiding chancre of chimpanzee number one, and on the thigh with the fluid from a papule. Thirty-five days later an erosion, which grew into a rather large ulcer, appeared on the penis, as well as on the thigh of the second animal. The lesion had reddened and indurated borders, and the neighboring lymph glands were enlarged. Fournier's comment was that "the form of these lesions gave altogether the impression of a superficial chancre of the skin." The enlarged lymph glands persisted, the animal eventually developed a cough and snuffles and died forty-five days after the first symptoms appeared. Supposedly an influenza-like bacillus precipitated death.

The features of this work which suggest syphilis chiefly are the length of the incubation period, the character of the primary sores, and the secondary eruption preceded by the second incubation period, in the case of the first ape. The enlarged lymph glands are also of some significance. Metschnikoff and Roux appear to entertain no doubt that they have produced syphilis in these animals, which are so closely related to man. We must remember, however, that other investigators assert that they have produced primary and secondary syphilis in various animals with this or that organism, which had been cultivated from syphilitic lesions. We have already discussed[3] some of these investigations. The scientific world appears to have accepted none of these results so far. The names of Joseph and Piorkowski are now behind a bacillus which they are strenuously trying to establish as the cause of syphilis. Other competent observers claim that this organism is a constant habitant of the normal urethra. It would now be in order for Joseph and Piorkowski to inoculate a few chimpanzees with their bacillus, as men are not available for the purpose.

The work of Metschnikoff and Roux is significant, but these two experiments, naturally, can not be taken as conclusive. Further work is strongly indicated. The animals are, unfortunately, rare and expensive, difficult to obtain and stand captivity poorly, but they should be forthcoming for this work. Here is an opportunity for French philanthropy.

### PURE MILK IN INFANT FEEDING.

The report[4] of the investigation that has been carried out by Drs. Park and Holt, under the auspices of the Rockefeller Institute for Medical Research, on the use of pure and impure milk among tenement children in New York City, is worthy of careful study. The outcome of the inquiry illustrates the extreme complexity of the conditions surrounding infant feeding and the importance of approaching the matter without preconceived opinions. In some respects the report may be held to emphasize an aspect of infant feeding that has not always been put to the fore in discussions. The importance of carrying out investigations of this character under actual tenement-house conditions rather than in institutions, or among the homes of the well-to-do, is shown by the remarkably concordant character of the results obtained through the co-operation of a considerable number of workers along clinical and bacteriologic lines.

Two or three features of the report stand out so conspicuously as to deserve special mention. The dangers from the use of raw milk in summer for infant feeding have been often insisted on, but they have rarely been so conclusively demonstrated. The milk used for the comparative tests was distinctly above the average as regards bacterial contamination, but in spite of this fact its employment in a raw condition was followed by illness in a large proportion of cases, while the same milk, when given after pasteurization, proved relatively wholesome. The facts presented on this head are so convincing that there seems no escape from the conclusion that the use of heated milk in summer, *irrespective of the initial bacterial content*, must be considered as by far the most important agent in diminishing infant morbidity and mortality. In the course of the investigation some difference was noticed between the amount of illness and mortality among children fed in hot weather with different kinds of milk, i. e., cheap "store" milk, condensed milk, pure bottled milk and breast milk. As already stated, however, the influence of the degree of contamination of the milk was quite overshadowed by the effects of heating. "The effect of bacterial contamination was very marked when the milk was taken without previous heating, but, unless the contamination was very excessive, only slight when heating was employed shortly before feeding."

---

[1] The Journal A. M. A., vol. xli, p. 971.

[2] Deutsche med. Wochenschrift, 1903, No. 50, p. 943. Briefly abstracted in The Journal, Jan. 9, p. 135.

[3] The Journal A. M. A., vol. xli, p. 261.

[4] Medical News, Dec. 5, 1903, p. 1066.

Other conclusions of considerable interest rather from the exact data by which they are buttressed than from their novelty, are that, during cool weather, the health of the infants observed was not appreciably affected either by the kind of milk or by the number of bacteria the milk contained. Children over three years of age showed no susceptibility at any season of the year to the use of milk containing even large quantities of bacteria. The bad sanitary surroundings so often found in tenement-house districts are apparently not in themselves a potent factor in contributing to infant mortality, although indirectly they may lead to laxity and indifference in matters of feeding. The authors remark on this head: "It is not, therefore, merely by better housing of the poor in large cities that we will see a great reduction in infant mortality." Great stress is laid on the necessity of educating mothers in the common civilized methods of the care of infants, and the point is made that this must be accomplished by personal association instead of by tracts and leaflets.

In brief, the report indicates that the use of heated milk and the instruction of the tenement-house mother in the ordinary methods of infant feeding as regards quantity, regularity, etc., are the reform measures that at present can be most hopefully undertaken. In its truly objective method of approaching the problem, as well as in its utilization of the co-operative plan of work, this investigation must rank as one of the most important studies yet made of the causes and modes of prevention of infant mortality in cities.

## UNION PRACTICALLY SECURED IN NEW YORK.

We print elsewhere in this issue a telegram announcing the acceptance and adoption by the Medical Society of the State of New York of the report of the conference committee on the union of the society with the New York State Medical Association. This will be glad news for all who appreciate the conditions that have prevailed in the Empire State for over twenty years. It means the solution of a problem that has long been recognized as a difficult one, and puts an end to a strife that has not been a credit to the profession. The thanks of the medical men of the whole country should be extended to those in both organizations, who have in recent years been striving to bring about this happy consummation. To those on the outside who do not know all the intricacies of the problem, it has appeared as though its solution was an easy matter, but the difficulties of the situation were real. As we understand it, the New York State Medical Association will be merged with the Medical Society of the State of New York, and the latter will amend its charter, reincorporate and will adopt the plan of organization recommended by the American Medical Association, subject to minor changes to suit local conditions. A bill has passed the legislature of the State of New York and has been signed by the governor, permitting the state society to enter into this consolidation plan.

## THE DOCTOR IN POLITICS.

THE JOURNAL has always emphasized the importance and advisability of the physician exercising his duties as citizen, and has repeatedly called attention to the influence he can exert for good on the community and profession. It has somehow become almost traditional in our profession that active citizenship and the pursuit of scientific medicine are incompatible. The brilliant examples which show that eminence in medicine is not always inconsistent with the fulfillment of the highest duties of citizenship and with the most exalted functions in the state, have apparently been taken only as the exceptions that emphasize the rule. In an address in our last issue, Dr. C. A. L. Reed takes up this subject in his own forcible and convincing way. He shows that civic duties are not to be neglected, if the physician is to fully meet the demands made on him by the public which trusts in him to guide them on matters relating both to their physical welfare and to the profession of which he is a member. The physician, as Dr. Reed says, is in touch with the public pulse as well as with individual opinions of his fellow-citizens, and he can influence these opinions as no one else can. His power for good, even in the most unobtrusive ways, seems hardly limited. It is not necessary for the physician to be a partisan, though he certainly has a right to his own convictions, but entirely aside from political partisanship, he can influence the public will and legislation on matters on which his special means of information and training qualify him to give expert opinions and valuable advice. If physicians would generally exercise this privilege, using their influence where they can affect public sentiment in the right direction, the results would be something that we have long been wishing for, and many evils that now curse the public and embarrass the profession in efforts for the public's welfare, would be suppressed or completely done away with. We have neglected our privileges too much. It is not, however, by individual work alone that the best results are to be obtained, but through organized effort. Much has been done already even in the desultory way in which medical men have worked for results, and it indicates how much more can be done with systematic and organized effort. We have had lessons enough to show us what can be done if the effort is made in the right way. In the early history of our country, as Dr. Reed points out, the medical men were the counselors, not only in medical matters, but in general affairs of the state. There were 22 physicians among the members of the Provincial Congress of Massachusetts in 1774 and 1775, and 5 physicians—a very respectable percentage of the whole considering the number in the country at the time—were members of the Continental Congress and signers of the Declaration of Independence. Since that time the medical profession has suffered, not only in public estimation, but also in political power, and it is time that we endeavored to bring about a change that will give to us something of the consideration which our forefathers received. This can be done only by organized effort.

### THE FOOTBALL FATALITIES AND INJURIES OF 1903.

Last spring we made arrangements for the collection of statistics regarding fatalities and injuries from the Fourth of July celebrations. The results which we presented were startling, for they showed a much larger fatality and a greater number of injuries than had been thought possible. Last summer we made similar arrangements for gathering the statistics regarding fatalities and injuries resulting from football. While the results of this game are not as bad and the fatalities not as numerous as are those from Fourth of July celebrations, at the same time they are sufficient to call attention to this vigorous sport and to influence one to make the query, "Does it pay?" Almost all our universities and schools now have football teams which engage in series of matches. College pride and college spirit are developed and improved by this game, and honest rivalry in manly sports and athletic exercises is encouraged, all of which is to be commended. A little more than twenty years ago the faculty of a university which now has a distinguished record in football, called before it a student who had been guilty of attempting to introduce to the students the Rugby game, and severely censured him because he was attempting to introduce a brutal sport. A professor of another university was widely quoted not long since as declaring that within the last ten years only twenty-three men had died from the direct results of the game of football in the colleges. If the statement be authentic, 1903 was a most unfortunate year for the devotees of the game. The fatalities and injuries of last year, however, were probably not more numerous or more grave than in recent years. While we do not wish to be considered as opposing legitimate athletic sports, we believe that in this particular game the human wreckage far outweighs the good resulting from three or four months of athletic exercise and training. Our statistics show that there occurred 35 deaths[1] during last year, and over 500 severe accidents to players. Beside these 35 deaths, there were 11 cases of spinal injuries, followed by paralysis, which in most cases seems to have proved permanent, and, consequently, worse than death. Sprains, contusions and scalp wounds have not been included in the list, although reports show that many of these injuries that were at first considered trivial finally resulted seriously. There were 343 fractures, most of them of the bones of the leg and forearm. There were 91 cases of fracture of the clavicle, 19 fractures of the femur and 4 of the skull. It is, of course, impossible to estimate accurately the number of permanent injuries received in these accidents, but when we consider that many of the fractures were compound, and 19 of them of the femur, we must believe that in this class alone the percentage of permanent injuries could not be very low. We can, without exaggeration, say that at least 50 deaths or permanent total disabilities resulted from the football games of 1903.

### THE ALBANY DIPHTHERIA STATISTICS.

The medical profession, and indeed the world at large, are now so thoroughly convinced of the efficacy of antitoxin in the treatment of diphtheria that new statistics can do little more than remind us of the security of our position in regard to the treatment of this disease. Nevertheless, it can not be said that we have yet learned all there is to know about the subject. The health office of Albany, N. Y., has recently, through Dr. Craig,[1] reported the diphtheria statistics of that city for the years 1901, 1902 and 1903. It was attempted to ascertain certain facts concerning all cases of diphtheria reported to the health office by the physicians of the city, whether or not the cases received antitoxin, and the results of the treatment. Unfortunately the day of the disease on which antitoxin was administered was not obtained. During this period there occurred a remarkable decrease in the number of cases from 632 in 1901, 356 in 1902, to 194 in 1903. One can not be certain that this is due to the use of antitoxin alone. Experience tends to show that the virulence and prevalence of diphtheria and other acute contagious diseases may vary greatly in succeeding years. That the antitoxin is of influence in limiting the number of cases can not be doubted seriously however. Cutting short the course of disease in a case, and the injection of a prophylactic dose into one who has been exposed to infection, must exert a potent influence in this direction. That the use of antitoxin should become more general was to be expected. Of the Albany cases, 81.6 per cent. in 1901 and 86 per cent. in 1903 received antitoxin. It is surprising that the percentage of mortality of the total number of cases has remained the same for the three years, about 7 per cent. This is not important, however, since in 1901 about eighty-two patients in every hundred received antitoxin, and in 1903 eighty-six, which slight increase would not affect the percentage mortality seriously. There is another important factor in this connection: A certain number of neglected cases will always be found in the crowded districts of cities, and among Eddyites and faith healers, where physicians are not called at all or not until it is too late; the deaths of such cases help to keep up the percentage of mortality, although the number of cases and ratio of deaths decrease among the more intelligent. One of Dr. Craig's conclusions is that "the medical profession is using mature judgment in the selection of cases for the use of antitoxin, the milder cases being permitted to go on to recovery without the use of antitoxin and the more severe cases, including the mixed infections, are given the benefits of protective inoculation." We are not willing to accept it as the opinion of the physicians of Albany that antitoxin should be withheld from any case of diphtheria, be it ever so mild. Aside from the fact that the danger to the community is lessened by shortening the course of the disease, the interests of the patient require the neutralization of the toxin. One needs only mention the possibility of diphtheritic paralysis to show that the indications for the administration of the antitoxin in liberal amounts are mandatory.

THE JOUR

[1] Albany Medical Annals, January, 1904.

---

# Medical News.

## ILLINOIS.

**Personal.**—Dr. and Mrs. Carey Culbertson, Piper City, have returned from a seven-months' stay abroad.

**Smallpox.**—A case appeared at Berwyn, Cook County, last week.——Springfield is now free from the disease.——An epidemic is said to be raging in New Athens.

**Hospital Staff Election.**—At the annual meeting, January 19, of the staff of St. Mary's Hospital, Quincy, the following officers were elected: President, Dr. John A. Koch; vice-president, Dr. John K. Reticker, and secretary-treasurer, Dr. F. T. Brenner.

**Canton Epidemic Subsiding.**—Inspectors from the State Board of Health have returned from a visit to Canton, and report that only a few cases of typhoid fever still exist, and that there seems to be no danger of a further spread. About 125 cases have been reported, with 17 deaths. At present the disease is confined to ten dwellings. The local health authorities, aided by the State Board of Health, are taking all measures practicable to put an end to the disease. All wells in the city have been condemned. Every possible effort is being made to cause a disinfection of excreta, and all infected houses will be thoroughly disinfected. The city council has appropriated the funds necessary to carry out the work of inspection and disinfection.

### Chicago.

**New Michael Reese Hospital.**—The committee now announces that it has received subscriptions for more than $200,000 of the $300,000 required to erect a new fireproof building.

**Ancker Not to Come to Chicago.**—It is now reported that Dr. Arthur B. Ancker has withdrawn his acceptance of the position of superintendent of the Presbyterian Hospital, Chicago, and his resignation as superintendent of the City Hospital, St. Paul, Minn.

**Deaths of the Week.**—During the week ended January 23, 517 deaths were reported, 49 less than for the preceding week, and 34 less than for the corresponding week of 1903. The annual death rate was 13.81 per 1,000. Pneumonia caused 106 deaths; consumption, 66, and heart disease, 47.

**New Children's Hospital.**—The Maurice Porter Hospital is to be torn down and replaced by a new building to accommodate sixty children. Mrs. Julia A. Porter has given $75,000 for the work. The present hospital was founded in 1882 by Mrs. Porter as a memorial to her son. At first it had 12 beds, but later 31 beds. The new building is to be a modern fireproof structure, with every facility for the care of sick children. The six requirements of the Children's Hospital Association, which will be specially followed, provide for an observation department, where children are kept two weeks before admission to the wards; an isolation department, laboratory facilities, pure milk supply, bedside and didactic instruction for nurses, and 1,000 cubic feet of air for each patient.

## MARYLAND.

**Railway Hospital.**—The contractors of the Wabash road are erecting a first-class hospital at Little Orleans for the use of the men engaged in tunneling and other heavy work in that section.

**Will Let Well Enough Alone.**—The Medical and Chirurgical Faculty decided at a meeting, January 20, not at this time to agitate the state medical law. Although defective, it was feared that tampering with it by the legislators might render it still worse. Application will be made to the legislature for $50,000 for two years to build a new medical hall, now imperatively needed.

**Registration of Nurses.**—A bill has been prepared for presentation to the legislature by the Maryland State Society of Graduate Nurses, providing for state registration of nurses, twelve members nominated by the society and appointed by the governor to serve as the examining board. The applicant must deposit a fee of $5. Those registered may use title "R.N." The act does not forbid nursing by ordinary nurses.

### Baltimore.

**Rush Medical Club.**—The Rush Medical Club of the University of Maryland will on February 4 celebrate its fifty-fourth anniversary.

**Sewerage Bill Introduced.**—The Baltimore City Sewerage Bill was introduced into the legislature, January 20. It provides $10,000,000 for the construction of the system.

**Smallpox.**—The British steamer *Parthenia* arrived in port last week with two cases of smallpox on board. The men and nurse were taken to Quarantine Hospital, and the ship and contents fumigated. The detention barracks at quarantine are complete. They consist of four wards, each accommodating 100 persons.

**Alumni Meet.**—The General Alumni Association of the University of Maryland held its annual meeting, January 21. An address on "The History of Dentistry and the School of Dentistry" was made by Dr. F. J. S. Gorgas, dean of the School of Dentistry. Dr. Eugene F. Cordell read a Latin university ode. B. Howard Haman, LL.B., was elected president and Dr. Eugene F. Cordell, secretary-treasurer.

**Deaths Reduced.**—There were only 188 deaths last week, 249 having occurred in the corresponding week of 1903; 27 were from pneumonia and 24 from consumption. The annual death rate per 1,000 was 17.70, the colored rate being, as usual, double that of the whites. Pneumonia is unusually and apparently increasingly fatal. A report from one of our leading hospitals shows a mortality of 40 per cent. of late cases.

## MASSACHUSETTS.

**Smallpox on Steamer.**—A case of smallpox was found among the firemen of the S. S. *Pomeranian* on her last arrival at Boston Harbor, and was quarantined on Gallop's Island.

**Physicians Will Inspect Schools.**—The board of health of Malden has appointed five local physicians as special agents to inspect schools and schoolhouses twice each week for the prevention of contagious diseases and the promotion of the health of the children.

**Police as Lodging-House Inspectors.**—The Boston police department has detailed two inspectors to devote their time to a daily inspection of the lodging houses of the city to be sure that the laws are complied with, especially the regulations of the board of health.

**State Hospitals Overcrowded.**—Further evidence of the extreme overcrowding of the state insane hospitals is contained in the annual report of the State Board of Insanity. With a total of 8,610 patients, an increase of 339 in the year, 1,753 are obliged to sleep on beds in corridors and day rooms.

**Limit Water Pollution.**—The Supreme Court has affirmed that the rules of the Metropolitan Water Board are valid in the restrictions they may place on dwellers on the water-shed. The case in question was of one James Dorr, a mill owner at Holden, whose mill polluted a tributary of the Nashua River.

**Many Cases Treated.**—At the quarterly meeting of the Boston Dispensary, it was reported that 6,936 new cases had been treated at the central office and 2,282 visits made outside, an average of 297 cases treated each day. In the districts 3,217 patients received 6,088 visits, making a total number of cases cared for by the physicians of 10,153. A new district has been established in Charlestown.

**Against Antivivisection.**—Protests against the antivivisection bill—house bill No. 174—in the legislature are to be based on the facts that the passage of the bill will prevent boards of health from making necessary experiments; the detection of bubonic plague, glanders, hydrophobia and similar diseases; the recognition of tuberculosis; the testing of disinfectants; the study of serum reactions of typhoid and paratyphoid, and the further investigations of bacteria.

**Mortality and Morbidity.**—During the seven weeks ended January 23 there were reported to the Boston City Board of Health 1,536 deaths, 7 less than for the same period last year and an average weekly mortality of 18.96 per cent. less. There were reported 452 cases of diphtheria, with 34 deaths; 291 of scarlet fever, with 21 deaths; 66 of typhoid fever, with 15 deaths; 1,077 of measles, with 19 deaths; 242 of tuberculosis, with 173 deaths. Pneumonia caused 272 deaths; whooping cough, 6; heart disease, 161; bronchitis, 55, and marasmus, 15; 260 infants under 1 year and 409 under 5 years of age died, while 359 deaths of individuals over 60 years old were reported.

**Death Rate of New England.**—Dr. Samuel W. Abbott, secretary of the State Board of Health, in a paper read before the American Statistical Association in Boston on "The Decrease of Consumption in New England," reported that the mean annual death-rate of New England for the past 50 years is 17.6 per 1,000, of which approximately 10 per cent. has been due to phthisis. The death rate from the latter is distinctly less, in the counties farthest from the seashore. Fifty years ago the mortality among women was fully 45 per cent. greater than that among men. During this period the mortality among both sexes has decreased, and is still decreasing, and now the mortality among women is even less than among men. He attributed the decrease to early diagnosis, better sanitation and more out-of-door life. Deaths from heart, kidney and brain diseases have increased, perhaps because more people survive phthisis, for these deaths are more among older people.

## NEBRASKA.

**Personal.**—Dr. B. O. Young, Lincoln, after a year in East Africa, has settled in Bluefields, Nicaragua.

**Treble Size of Hospital.**—Plans are being prepared for the enlargement of Clarkson Hospital, Omaha, which is to be trebled in size. The work on the new buildings is to be commenced in the spring.

**To Be on Cottage Plan.**—The new hospital for the insane to be erected at Norfolk is to be built on the cottage plan, which, the committee decided, was the most sanitary, desirable and inexpensive plan.

**Medical Society of the Missouri Valley.**—The semi-annual meeting will be held in Lincoln, March 24, under the presidency of Dr. A. D. Wilkinson, Lincoln. A symposium on pneumonia will be a feature of the program.

## NEW YORK.

**Communicable Diseases.**—The board of health of Lockport has closed the public and parochial schools and business colleges, also the theaters. Men will be set at work fumigating all public places and street cars because of the smallpox.——There are 33 cases of scarlet fever at Dunkirk.——Smallpox has abated at North Tonawanda.

**Personal.**—Dr. W. J. Fleming, Troy, has been appointed physician in the department of charities and correction.——Dr. William Hailes, Jr., has been appointed consulting surgeon. Dr. Edgar Van [illegible] surgeon; Dr. Sautter, assistant attending [illegible] Albert Vander Veer, surgeon-in-chief, and [illegible] attending surgeon, in the Albany Hospital.

**Needs of State Hospitals.**—The eleventh annual report of the state charities aid associations has been forwarded to the State Commission in Lunacy. It states that on Oct. 1, 1903, there were in the various state hospitals for the insane, 2,666 patients in excess of the capacity of those institutions. The building operations now under way will provide accommodations only for the overcrowding existing at the present time and make no provision for the future. Estimating the annual increase at 700 for the state more accommodations must soon be made. There are two ways of providing for these patients: First, by enlarging the existing hospitals, and second, by building new hospitals. At Utica, Willard, Hudson River, Middletown, Binghamton, King Park and Manhattan, the accommodations for acute cases are unsatisfactory, and each of these hospitals should be equipped with a reception pavilion. At Binghamton and Gowanda, by acquiring more land, 1,350 more patients could be cared for. In large cities psychopathic or reception hospitals could be built for the curative treatment of the acutely insane or for the preventive treatment of incipient cases, and large hospitals on the colony plan in the country for the acute and chronic cases. The association estimates the requirements for 1904 to be appropriated by the legislature at $6,710,000. It is urged that a larger allowance of milk and eggs for patients be permitted. Cases of pulmonary tuberculosis might perhaps be prevented if the milk and eggs that are now furnished after the patients develop the disease were provided earlier. The per capita cost of food at present is but 15 cents a day.

### Buffalo.

**Hospital Needed.**—Health Commissioner Greene has again petitioned the board of aldermen for a new quarantine hospital. The present hospital is said to be unfit for human habitation. Bonds have been issued and a site selected for the new hospital, and there should be no excuse for further delay.

**Personal.**—Dr. Eugene A. Smith has been appointed surgeon of the Fourth Brigade, N. G., N. Y., with the rank of lieutenant-colonel, vice Dr. Floyd S. Crego, resigned.——Dr. Joseph Burke has been made a surgeon-in-chief of the Lackawanna steel plant hospital at Stony Point.——Dr. William C. Krauss has been elected president and Dr. Vertner Kenerson, secretary, of the Emergency Hospital staff.

**Opticians Not Physicians.**—The Buffalo Academy of Medicine has adopted resolutions on the proposed bill to give opticians medical standing (see The Journal, January 23, p. 255). They call attention to the very decided harm that can be done to patients unless the person who prescribes glasses for them has a knowledge of medicine as well as of optics, and express the sentiment of the academy as unalterably opposed to giving the privilege of the practice of medicine to any persons not qualified for this responsibility by a knowledge of the fundamentals of medicine, to wit, anatomy, physiology, chemistry, pathology, physics and hygiene as demanded by the state examining boards.

### New York City.

**Increases Tuition Fee.**—Columbia University College of Physicians and Surgeons has increased the annual tuition fee from $200 to $250, because of increased cost of instruction. This is in force beginning July 1, 1904.

**Presentation to Lederle.**—The employes of the health department, on January 18, presented to former Health Commissioner Ernst J. Lederle a solid silver tea service, a gold match box and half a dozen porcelain cups and saucers, the presentation being made by Dr. Herman M. Biggs.

**Society Election.**—The annual election of the Medical Society of the County of Kings, held January 19, resulted as follows: President, Dr. John E. Sheppard; vice-president, Dr. James W. Fleming; secretary, Dr. William S. Hubbard; associate secretary, Dr. William C. Woolsey; treasurer, Dr. Onslow A. Gordon; associate treasurer, Dr. John R. Stivers; directing librarian, Dr. James M. Winfield, and censors, Drs. Henry G. Webster, James P. Warbasse, William F. Campbell, William F. Dudley, and Walter C. Wood, all of Brooklyn.

**New Medical Society.**—The East Side Physicians' Association of the City of New York was organized, January 15, with the following officers: Dr. Ignatz M. Rottenberg, president; Drs. Maurice J. Burnstein and Frederic N. Wilson, vice-presidents; Dr. Nathan Friedman, secretary; Dr. Maurice Caspe, treasurer; Dr. Sigmund A. Tarler, chairman of ways and means committee; Dr. William S. Gottheil, chairman of committee on ethics; Drs. Robert Abrahams, Abram Brothers and Max Landesmann, trustees, and Drs. Maurice M. Berger, Julius Solow, Waldemar Dorfman, Pierre A. Siegelstein, and Isidor Ritter, committee on admission.

**Instruction in Special Lines.**—Cornell University Medical College has inaugurated special instruction and lectures by some of the subordinate professors and assistants, who are conducting more or less specialized lines of research. In addition, these lectures will present summaries as well as detailed knowledge of all the advances made in these different branches. As illustrations may be mentioned, in the department of general surgery, Professor Kammerer on "Intestinal Obstruction." and Prof. A. B. Johnson on "The Surgical Disorders of the Breast"; in general medicine Dr. Conner on "The Ductless Glands," and Dr. Camac "The Practical Aspects of Infection and Immunity." These lectures will be delivered before the fourth and third year classes of the college. Some of the subjects, however, are of such general interest that invitations will be sent to all members of the faculty and practitioners who may be interested.

## OHIO.

**Personal.**—Dr. Wilfred J. Taylor, Dayton, has been appointed physician to the Montgomery County Infirmary.——Dr. Francis Alter, Toledo, has gone abroad for a year.

**New City Hospital.**—On January 20 a fully attended meeting was held in the Cincinnati Hospital, consisting of the medical staff, the board of medical advisers, the hospital commission, and the members of the board of public service, to decide on plans for the new city hospital. The consensus of opinion was that the cottage plan in vogue at Johns Hopkins and many of the large European hospitals would be the best.

**Societies and Elections.**—Montgomery County Medical Society.—At the annual meeting the following officers were elected: Dr. John C. Reeve, Jr., president; Dr. Henry S. Kimmel, vice-president; Dr. Wilfred J. Taylor, secretary; Dr. D. C. Sichliter, treasurer; and Dr. Duff W. Greene, censor, all of Dayton. The secretary's annual report showed a total of 278 practitioners, or about one to 480 of the population. There were 34 new registrations in the county during the year.

Cincinnati Society for Medical Research.—On January 21 this society elected the following officers: President, Dr. David I. Wolfstein; vice-president, Dr. A. Knight; secretary-treasurer, Dr. Samuel I. Iglauer.

Dayton Academy of Medicine.—The academy has elected the following officers: Dr. Daniel B. Conklin, president; Dr. William A. Ewing, vice-president; Dr. Matthew Porter, secretary; Dr. William A. Burns, treasurer; Drs. William C. Marshall, Herbert C. Haning and Clifton L. Patterson, censors, and Drs. Edwin M. Huston, Richard S. Gaugher and A. H. Dunham, entertainment committee.

Academy of Medicine of Toledo and Lucas County.—At the annual meeting the following officers were elected: President, Dr. John A. Wright; vice-president, Dr. Charles Betts; recording secretary, Dr. Charles P. Wagar; financial secretary, Dr. Pringle G. Tait; treasurer, Dr. Willis W. Grube; censors, Drs. Herbert E. Smead and William J. Gillette, and member library board, Dr. A. L. Steinfeld.

Clinton County Medical Society.—At the annual meeting, held December 30, the following officers were elected: Dr. Allen T. Quinn, Wilmington, president; Dr. Samuel B. Lightner, Sabina, vice-president; Dr. Eldorado C. Briggs, Wilmington, secretary, and Dr. Rodney T. Trimble, New Vienna, delegate to state society. The society was reorganized under new constitutions in May, 1903, and has received a charter from the state society.

Medical Officers' Association of the Ohio National Guard.—The medical officers of the national guard of the state met at Columbus, January 11, and effected an organization, electing the following officers: President, Surgeon-General Edmund C. Brush, Zanesville; vice-president, Surgeon-Major Fred C. Weaver, Dayton; secretary and treasurer, Surgeon-Major Trevanion V. Dupuy, Dayton, and executive committee, Surgeon-Captains James H. Wright, New Lexington; Sterling B. Taylor, Columbus, and Herrick, Cleveland.

Canton Medical Society.—This society held its annual meeting, January 5, and elected the following officers: President, Dr. David F. Banker; vice-president, Dr. Edward S. Folk; recording secretary, Dr. Charles A. Crane; corresponding secretary, Dr. George F. Zinninger; treasurer, Dr. Frank Da Hinden, and censors, Drs. Charles E. Schilling, Frank W. Gavin, and Edward O. Morrow. The society held its second annual banquet January 8. Dr. Edwin Ricketts, Cincinnati, delivered an address on "Infection of the Biliary Output." About 70 physicians were present.

## CANADA.

**Toronto University Expenses.**—The estimates of Toronto University for the current year have been prepared in readiness for presentation to the Ontario legislature, now in session. They call for an expenditure of $150,663.50, exclusive of the departments sustained by the government.

**Sensible Treatment of Antivaccinationists.**—The Antivaccination League of Toronto interviewed Premier Ross last week and presented their views in favor of making vaccination optional. Premier Ross told the deputation to go before the Provincial Board of Health and try to persuade them to recommend the legislation.

**Ontario Statistics for December.**—The December death rate in Ontario was on a level with the average. There was a total of 2,141 deaths. Contagious diseases numbered: Smallpox, 13 cases, no deaths; scarlet fever, 231 cases, 20 deaths; diphtheria, 473 cases, 71 deaths; measles, 14 cases, one death; whooping cough, 8 cases, 4 deaths; typhoid fever, 120 cases, 24 deaths. There were 146 deaths from tuberculosis.

**The Typhoid Situation in Montreal.**—Typhoid fever was the cause of nine deaths in Montreal during the week ended January 16. The deaths from all causes during that week were 122, an average rate. There are now between 120 and 130 cases of typhoid fever in the Montreal hospitals, and no new cases can be taken into either the General or the Royal Victoria. The epidemic appears to be practically over. Only two new cases have been reported in Westmount during the past four days, this making the total in that suburb 77 since the epidemic started. The Quebec Board of Health sent out an official circular to all Montreal physicians requesting their co-operation in quelling the outbreak.

**Annual Report, Royal Victoria Hospital, Montreal.**—Jan. 1, 1903, there were 188 patients in the Royal Victoria Hospital, Montreal. During 1903, 2,911 were discharged, of whom 1,397 were well, 914 improved, 165 not improved, 293 not treated, and 142 died. There were remaining in the hospital, Dec. 31, 1903, 208. Of the 142 deaths 38 took place within forty-eight hours of their admission. Deducting these the death rate has been 3.57 per cent. In the out-patient department the total number of patients treated was 4,308. The number of visits of these patients aggregated 23,638. The income for the year amounted to $140,368, while the ordinary expenditure amounted to $120,419. The total cost per patient per day was $1.62½.

**Personal.**—Dr. T. J. Moher, assistant superintendent of the Institution for the Feeble-Minded, Orillia, Ont., has been made medical superintendent of the Asylum for the Insane, Brockville, Ont., in place of the late Dr. Murphy.——Dr. Peter H. Bryce, secretary of the Ontario Board of Health, has been appointed inspector of immigration of the interior. He will probably be succeeded on the board of health by Dr. C. A. Hodgetts, who for some time past has been provincial health inspector.——Prof. W. D. Halliburton, F.R.S., professor of physiology in King's College, London, England, delivered a lecture, January 22, to the medical faculty and students of Toronto University, on "Degeneration and Regeneration of Nerves," with lantern slide illustrations.

**Annual Meeting Western General Hospital, Montreal.**—At the annual meeting of the Western General Hospital, Montreal, last week, the reports showed that the number of patients treated during 1903 was larger than ever before. After deducting the cases which terminated fatally within 48 hours of admission, the death rate was only 3 per cent. The report also stated that a new hospital building was becoming more necessary every day. Those treated in the hospital numbered 600; in the outdoor department, 7,560, an increase of 990 over the previous year. The average number of days' stay in the hospital was 18.3. Dr. G. H. Matthewson was elected secretary, and Drs. F. R. England and F. W. Campbell medical representatives on the board of governors.

## FOREIGN.

**Sixth International Congress of Physiology.**—Brussels will welcome this congress Aug. 30 to Sept. 3, 1904. Communications should be addressed to Dr. Slosse, Institute Solvay, Parc Leopold, Brussels, Belgium.

**Decrease of Malaria at Rome.**—The *Riforma Medica* proudly states that the death rate at Rome is now one of the lowest in any city. The mortality from malaria has fallen from 650 in 1881 to 76 in 1901. As the population has increased during this period by 170,000 inhabitants, the mortality quotient from malaria has dropped from 21 to 1 per 10,000 inhabitants.

**Sardou, the Playwright, a Medical Student.**—Victorien Sardou it seems was a medical student at one time, and relates that he and his mates made a special study of hypnotism and hysteria long before Charcot. He believes that the phenomena of hypnotism and hysteria explain all the magic and witchcraft of the ages. His play, "La Sorcière," in which Sarah Bernhardt is starring at present, is based on these memories of his days as a medical student.

**French Congress of Gynecology, Obstetrics and Pediatrics.**—The fourth periodical congress with the above title is announced to convene at Rouen, April 5 to 10, 1904. Professor Richelot of Paris will preside over the general sessions, Guillemet of Nantes over the section for obstetrics, and Kirmisson over pediatrics. The secretary is Dr. A. Martin, 6 Place de la Cathédrale, Rouen; subscription, $4. The congress is open to all physicians, philanthropists, medical students and midwives.

**Chantemesse, the New Inspector-General of the French Sanitary Service.**—Dr. Chantemesse, professor of experimental and comparative pathology at the Paris Faculté de Médecine, has been made inspector general of the sanitary service, in the place left vacant by the recent death of A. Proust. He has for years taken an active part in the campaigns against epidemic diseases, against plague in Spain, cholera in Egypt and Portugal, and typhoid fever in France, either personally or by consultation. Jules Renault and P. Faivre have been appointed inspectors under him.

**Proportion of Deaths to Attendance at Theater Fires.**—The *Gazette Méd. de Paris* states that in a theater panic and fire about one out of every three spectators perishes. This was the proportion at the Brooklyn Theater fire in 1876, with 400 victims; at Nice in 1880, with 65 victims; at the Ring Theater at Vienna in 1881, with 600 victims; at Smolensk in 1883, with 380; at the Opera-Comique at Paris in 1887, with 131; the Exeter Theater in England, with 127 victims, in 1887; at the Oporto Theater in 1888, with 80, and at the Iroquois Theater in Chicago, where 573 perished.

**Discontinuance of Indian Medical Record.**—This journal, published in Calcutta, stops with the fifty-second number of its twenty-fourth volume. It was formerly published by Dr. J. R. Wallace, and since his death the executors of his estate have continued it. They now announce that it is necessary to discontinue. The journal has been the exponent of the Anglo-native medical element, as contrasted with the official service. One of the noteworthy stands it took was in opposition to the for-revenue-only opium report. It was one of the best of our Indian exchanges, and we regret that it is no longer to be published.

**Swedish Medical Association Prize.**—This prize of $270, for 1903, was awarded to Prof. M. G. Blix of Stockholm for his research on the temperature of the muscles. No communications were received in competition for the Alvarenga prize. Among the foreigners elected members of the association during the year were Nicholas Senn of Chicago, N. R. Finsen, B. Bang, I. Pawlow of St. Petersburg, Zuckerkandl, Waldeyer and L. Meyer, T. Rovsing, A. Krogius and several other prominent Scandinavians. The association prize for 1904 will be awarded for some medical theme. Prof. P. J. Wising will resign as editor of the society journal, *Hygiea*, next June.

**Northern Congress of Surgery.**—This congress of the surgeons of the northland will be held at Göteborg, August 9 to 11, 1904. Four questions have been appointed for discussion, with addresses as follows: "Functional Tests of the Kidneys," addresses by T. Rovsing and by J. Nicolaysen; "Treatment of Extra-uterine Pregnancy," addresses by L. Meyer and O. Boije; "Early Operation in Appendicitis," addresses by A. Krogius and F. Bauer, and "Indications for Operation in Affections of Biliary Passages and Pancreas," with addresses by H. Ström and G. Naumann. The latter is the secretary of the congress, his address being: Viktoriagatan 2a, Göteborg, Sweden.

**Admission to International Congresses.**—The national committee for Great Britain has passed resolutions to the effect that international medical congresses shall in future be limited to physicians who apply for membership. Scientists whose names are presented by the national committees may also become members. These were the restrictions adopted at the Paris International Medical Congress, but the Madrid Congress disregarded them and opened its doors to a promiscuous throng. The above resolutions drawn up by the British committee have been forwarded to the executive committee of the approaching International Medical Congress to be held at Lisbon.

**Progress for Women Physicians in Sweden.**—In January, 1901, the women physicians of Sweden presented a petition to the king asking that women be allowed to compete for the various official medical positions, which had hitherto been restricted to male candidates. After long consideration King Oscar has issued a decree, dated Nov. 6, 1903, which grants nearly all the demands of the petitioners. The only medical positions from which they are still excluded are those in the railway service and some minor posts. The decree further states that if a woman in an official medical position marries this step shall be accepted as implying resignation of her position.

**First International Congress of School Hygiene.**—This is to be held at Nuremberg, April 4 to 9. Addresses are to be made on "What Has Ophthalmology Done for the School Children, and What Has It Yet to Do?" by H. Cohn of Breslau; on "The Present Status of School Hygiene in Norway," by A. Johannesen of Christiania; on the "Hygiene and Personal Illnesses of the Teachers from the Standpoint of Their Relations to Their Pupils," by Le Gendre of Paris; on "Organization of the Public Schools According to the Natural Capacity of the Children," by Sickinger of Mannheim; on the "Task and Training of School Inspectors," by Liebermann of Budapest; on "Prevention of Infectious Diseases in Schools," and on "Suicide Among School Children," by Eulenburg of Berlin.

**Baccelli Leaves the Italian Cabinet.**—For two years Baccelli has been minister of the department of public instruction or of agriculture, and has accomplished some notable reforms along various lines while in office. He has now returned to his beloved clinic at Rome, and the occasion was celebrated by his friends with much rejoicing. The legislation adopted by his efforts to combat malaria, pellagra, etc., will have far-reaching effects, as also the legislation he secured to prevent child labor. He loses no opportunity to proclaim his opinion in regard to the necessity for combining medicine and politics, and urges medical men to enter political life. Experienced physicians are far better able to decide many of the questions that press for solution than lawyers or professional politicians, he believes, and deplores the general neglect of these opportunities.

**New German Postgraduate Organ.**—The committee in charge of the semi-official, extensive postgraduate courses now organized in most of the German cities from the central headquarters in Berlin, has founded an organ, the *Zeitschrift f. ärztliche Fortbildung*. E. v. Bergmann and M. Kirchner, with R. Kutner, form the editorial staff. The chief aim of the review will be the publication of comprehensive lectures delivered in the various courses. The first number has appeared, and publishes an appeal from the minister of public instruction calling on those in charge of the courses to pay special attention to training those who attend in the diagnosis and treatment of venereal diseases, and also to impress on them the all-importance of prophylactic warnings and advice to the public, to urge the necessity for avoidance of venereal disease and for its prompt treatment when acquired.

**Anglo-American Medical Association.**—A photograph of the members of this association is reproduced in the *Berlin and Continental Herald*, Dec. 12, 1903, thirty-five members being presented. Among them are many familiar faces from Chicago, New Orleans, and other cities. The association was reorganized in October, with Dr. J. H. Honan, now a resident of Berlin, president; and Dr. J. Cheston King, Atlanta, Ga., secretary and treasurer. Its object is to impart information to the English and American physicians coming to Berlin to study, to direct and advise regarding the post-graduate work in the university, clinics and hospitals, and to give valuable hints and suggestions, the result of the experience of those who have been longer in Berlin. A meeting is held every Saturday night, and an address is usually given by some eminent man, such as Ewald, Hoffa and Oppenheim. Dr. Ewald appears in the photograph mentioned.

**Laboratory for Curie.**—A prophet is not without honor save in his own country, but after other countries do him honor, his own compatriots usually look on him with different eyes. This was exemplified in the case of Ramon y Cajal, whose famous researches were conducted with the most modest resources and means until an international prize was bestowed on him, after which the Spanish government appropriated funds and a special laboratory for his further research. Since one of the Nobel prizes was awarded to Curie and Becquerel, France is heaping honors on them, and has taken steps to supply Curie with a new laboratory. The minister of public instruction has appealed to the parliament for an appropriation to found a new professorship, a chair of general physics, for him. He has declined to be decorated with the cross of the Legion of Honor, which was conferred on him at once, and it is more than probable that he will decline the professorship, as his time is already occupied.

**Alumni Reunion at Mexico.**—The alumni of the National Medical School of Mexico, who commenced their course twenty-five years ago, gathered at Mexico, January 7, for their first reunion. Out of a total of 94 only 34 per cent. are still living, and some of these were unable to attend. In scarcely more than twenty years of professional career death has claimed 66 per cent. As a souvenir of the occasion each wrote in an album some thoughts on the life of the physician. One wrote that "The physician has to carry not only his own burdens but those of other people"; another, "Medicine is most beautiful in theory but horrible in practice"; another, that he longed for a physician who "could cure him of the necessity for curing others." Others wrote on the great contrast between their early ideals of the life of the physician and what they have found it in reality. One commented that the soldier "dies for his country, but the physician lives for it and works that others may live for it too."

---

## CONSOLIDATION IN NEW YORK.

### The Society Approves the Plan for Union.

*(By Telegram from Our Special Correspondent.)*

Albany, N. Y., Jan. 26, 1904.

At the first session of the Medical Society of the State of New York, beginning here to-day, the first order of business following President Bristow's address was the report of the committee of conference appointed last year to act with a like committee from the New York State Medical Association looking to the union of the two bodies. The report was an able review of the year's work, including an account of the permissive act which was passed by the general assembly, and approved by the governor, to overcome the legal difficulties in the way of union The report concluded by recommending the adoption of the complete plan of organization of the American Medical Association for the government of the joint body, with only such changes as may be found to be necessary to adapt it to local conditions Dr Bristow had made an earnest plea for unification in his address, and after able addresses of endorsement by Drs Jacobi, Roosa, Potter, McDonald and Park, and without a word in opposition, the report of the committee was adopted with much enthusiasm Representatives of the association are here in cordial co-operation with the society people, and it apparently only remains for that body to act for the union to be completed.

## Correspondence.

### Sugar Metabolism and Diabetes—A Question of Priority.

Chicago, Jan. 22, 1904.

*To the Editor*:—In an able editorial published in a recent issue of The Journal (1903, p 1480) you call attention to Cohnheim's discovery that the pancreas mixed with muscle tissue possesses the power of destroying sugar, and you properly emphasize the fundamental importance of this finding inasmuch as it aids in interpreting the rôle of the pancreas in sugar metabolism and diabetes You also say, "Of course this does not preclude the possibility of a similar combined effect with substances in other tissues of the body where sugar is burned" As a matter of fact, another investigator, working simultaneously with Cohnheim, discovered that pancreas and liver combined also possessed sugar-destroying powers. You lay particular stress in this editorial on the fact that the pancreas alone, or the different tissues of the body alone, can not destroy sugar, whereas the addition of pancreas to different organs probably bestows this power on them, and you say: "Why it had not occurred to any one that it might be the work of the two together is the chief mystery."

I wish to call your attention to two reports of experimental work that I published in 1902 In these I showed conclusively that a mixture of pancreas extract and hemoglobin possesses the power to a marked degree of destroying sugar (and that incidentally in this process the hemoglobin is converted into bile acids and bile pigments, a conversion that takes place only in the presence of sugar) Commenting on this discovery, I say in one of these articles ("Some Experiments on the Formation of Bile Acids and Bile Pigments,' *Phila. Med Jour*, 1902, p 143), "A considerable proportion—of the pancreatic ferments —is secreted internally and is poured into the blood and lymph-stream to perform an important function in intracellular digestion—viz, proteolysis and glycolysis" In the other paper ("An Experimental Investigation into the Causes and Treatment of Diabetes," *Am Jour Med Sci*, 1902, p 669), I say in referring to these experiments, "a determination of the sugar before and after showed that a considerable quantity of the sugar had been destroyed, in other words, trypsin (I use this term for an alcoholic precipitate of pancreas extract) in the presence of hemoglobin, possesses glycolytic powers"

The principle, therefore, of the combined action of pancreas and an albuminoid body in promoting sugar destruction was established at that time, and until proof to the contrary is forthcoming, I do not consider it at all improbable 'that the hemoglobin contained in the muscle and liver tissues employed by the investigators mentioned is the substance that is destroyed by pancreas, while at the same time some sugar is burned up in the process

I am writing you this, anent another very able and very true editorial that you published some months ago, in which you decry the tendency on the part of certain European writers to ignore American contributions to science, and in which you charge them with unpardonable ignorance of our American literature.

Alfred C. Croftan.

### Depressant Drugs and Sudden Death.

Greenville, Ohio, Jan. 22, 1904.

*To the Editor*:—I believe that the reasoning in your editorial on "Depressant Drugs and Sudden Deaths" (The Journal, Jan. 16, p. 177), is at fault when you say that "a portion of the decrease in the number of sudden deaths from heart disease to population, has been ascribed definitely—and with considerable plausibility—to a certain cause," which, in substance, you say is that, owing to steps taken by the Board of Health of New York City to prove that a certain coal-tar product was being adulterated by the addition or substitution of acetanilid, and owing to threatened exposure and prosecution the substitution had abated to the extent of reducing the death rate from heart disease from the ratio of 1.31 in a thousand in 1902 to 1.28 per thousand in 1903. It seems more plausible to ascribe this decrease in mortality to the awakening of the public generally, and of physicians especially, to the fact that all of the coal-tar products are dangerous to life and a menace to health when used indiscriminately as heretofore.

Substitution is held in abhorence by the medical profession, which, ever ready to encourage any legitimate means to suppress sophistication in medicine, should not stop in its research when it has found one adulterated article, but should search with renewed vigor for everything that is likely to be adulterated with anything injurious to health.

It occurs to me that it would be interesting to have the statistics of other cities so that we could study the comparison. In a paper read at the meeting of the American Pharmaceutical Association at Mackinac Island, last August, G. M. Beringer gives us the analyses of 182 samples of this coal-tar product, obtained from seven cities in the United States, and of nine samples obtained from Newark, N. J., not one was adulterated, while of the sixty samples obtained in New York City, 50 were pure, 7 grossly adulterated and 3 contained traces of adulterants Baltimore shows the largest per cent. of adulteration, for out of 45 samples 18 were adulterated, so that accordingly we should find the death rate from heart trouble to be greater in Baltimore than in New York, and in the latter city greater than in Newark If, as the manufacturers assert, more than five thousand druggists of the United States are stocked with a spurious product, how is it possible for any physician who prescribes this article to have any assurance that his prescription will be filled properly?

It would be better for the public if our profession would teach it to look on proprietary medicines generally as being protected by a wilful perversion of law, and an attempt to substitute for the old patent and trademark system, a system of unlimited monopoly, preventing competition, instead of inducing manufacturers to improve methods of manufacture for the purpose of excelling one another in producing the same article of a better quality or at a lower price

Philip Dickes, M D.

### Firm Desires to Purchase Fraudulent Testimonials.

Flint, Mich., Jan. 23, 1904.

*To the Editor*:—I received this morning a letter, of which the following is a copy:

Chicago, Jan 22, 1904

*Dr C. B Burr, Flint, Mich*

*Dear Doctor*:—Your name has been handed us with a few other thoroughly reliable physicians in the United States, and referred to as well known throughout your part of country, and for this reason we are making you the following splendid proposition

We are now ready to furnish to the medical profession a new electric medical bath machine on which we secured patents Sept. 30, 1903 This new therapeutic (sic) instrument is admitted by medical experts to be the best physician's medical battery ever put on the market It was invented by an electric genius, and is no doubt considered the most perfect instrument of its kind ever placed on the market, and we guarantee it in every respect

We are just printing a new catalogue and in it we would like to have a few testimonials from some reliable physicians throughout the United States As we have got but five days before this book goes to press we have decided to give each of these physicians one of these outfits as per enclosed illustration, absolutely free, on receipt of the enclosed testimonial plainly signed in your own hand writing.

On receipt of this testimonial we will ship you one of these physician's outfits absolutely free.

Trusting that you will give this your prompt and immediate attention, and thanking you in advance for this favor, we remain,

Respectfully yours, U. S. STANDARD ELECTRICAL WORKS.
Per F. J. Osius, Pres.

Enclosed with the letter was the following, which it was hoped I would sign and return:

November 17, 1903.

*U. S. Standard Electrical Works, Chicago, Ill.*

*Gentlemen:*—I am pleased to recommend your Electric Bath Machine. I have used one for the last few weeks and will say that I could not afford to be without it. Please ship me another by return express and greatly oblige, Very truly yours,

Enclosed also was a cut of the machine for which the lying endorsement was requested. I shall respond to the communication as follows:

*United States Standard Electrical Works:*

Your letter of the 22d inst. is received. I am perfectly astounded by it. Is it possible that you expect a *reputable physician* who *has never seen your bath* to sign a letter dated Nov. 17, 1903, stating that he recommends it and that he has "used one for the last few weeks?" You say that on receipt of a testimonial for which the form is prescribed, one will be sent without cost. The proposition seems to me wholly corrupt and I think it my duty to give it publicity in THE JOURNAL of the American Medical Association.

C. B. BURR.

Very truly yours,
C. B. BURR.

## Organization in Iowa.

IOWA CITY, IOWA, Jan. 22, 1904.

*To the Editor:*—In behalf of and in justice to the medical profession of Iowa, I submit the following corrections. Dr. McCormack, in his "Plea for Unification" (THE JOURNAL, Jan. 16, 1904, p. 167), uses the following language:

> It is true that in nearly every state where this plan of organization has been proposed, as was natural and to be expected, academic and purely theoretical objections have been made to some feature of it, usually to the council, the house of delegates or to coincident membership. Such objection has always been made in advance of a trial of them, *and they have been confined almost entirely to states which have been practically without organization heretofore. Conditions in Iowa illustrate this point well.*

I have italicized what seems to me a totally unjust and probably unintentional use of Iowa as an example, which, as it stands, is open to interpretation the furthest possible from the truth of the case. We assert, for the medical profession of Iowa, that it has been not only well organized, but that in proportion to the population it has been the best organized and the most harmonious in its associations of any state in the Union. Its state society numbers 805 members, all (except 15, with more than thirty years' membership) having entered as delegates from county societies. Iowa has 543 members of the American Medical Association, a number exceeded only by New York, Pennsylvania, Ohio and Illinois. Nor are the objections in Iowa of the nature alleged by Dr. McCormack; there has been no objection to the principles of the original report of the committee on reorganization, as made by Dr. McCormack, at St. Paul in 1901. There have been and are objections to the validity of the alleged adoption of the "standard" at Sioux City, April 17, 1903, and to the "standard" as representing the principles of the St. Paul report. C. M. HOBBY.

## Fifteenth International Congress of Medicine.

Dr. John A. Wyeth, New York City, has sent us a letter which he has received from Prof. Miguel Bombarda, secretary-general of the International Congress of Medicine to be held at Lisbon in 1906. Dr. Wyeth expresses the hope that the unpleasant experiences of our delegates at Madrid will not deter us from taking an interest in the Lisbon congress. He suggests that it would be well for THE JOURNAL of the Association to inaugurate this movement by printing at this time this invitation.

A translation of the letter referred to is as follows:

LISBON, Dec. 22, 1903.

*Sir and most honored confrère:*—At the last international congress at Madrid, Lisbon was designated as the place of meeting of the Fifteenth International Congress of Medicine, and the medical profession of Portugal, appreciating the great honor conferred on it, accepted with pleasure the decision of the representatives of the various countries gathered at Madrid and set about the work with the greatest enthusiasm. The executive committee and the committee on organization have already been appointed, and the various sections of the congress now being formed will complete the organization. Following the precedence of former congresses the executive committee has decided to establish in all the countries which will send delegates to Lisbon, subcommittees or bureaus of information, being convinced that with the hearty co-operation of the profession the Fifteenth Congress will achieve the end for which this international scientific gathering was intended, viz.: the advancement of medical science. For this reason I appeal to your aid in organizing the bureaus of correspondence and of information in the United States.

MIGUEL BOMBARDA, Secretary-General.

# Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

### PASTORAL MEDICINE—THE BUSINESS SIDE OF PRACTICE

CHICAGO, Dec. 22, 1903.

*To the Editor:*—I would like to see in your Minor Comments Department what you think in regard to the addition to the medical course in colleges of lectures in what might be called pastoral medicine analogous to those on pastoral theology in divinity schools. The latter covers the relation of the minister to his flock collectively and individually, to his fellow clergymen, to church property, to types of human nature, etc., covering a number of things relating to the success of his work. It seems to me that we who are students ought to have the benefit of lectures by an experienced man with a broad outlook on human nature and with the ability to handle the questions relating to the physician's getting on in the world, having granted a reasonable scientific equipment. Such things as location, buying a practice, relations to other physicians, to politics, requirements for office, location of office, how to make a professional call or how not to make one, are a few of the things that might be covered. It seems to me the young physician might be headed off from a great many blunders in this way.

E. P. S. MILLER ('05, P. & S.).

ANSWER.—Our correspondent has touched on a matter that has always seemed to us of great importance. The first duty of a medical school is, of course, to impart a thorough and scientific knowledge of medical matters. But it might well go a little further and instruct the young physician regarding the right way to put his knowledge to practical use as a means of earning a livelihood. To be sure, each man has to work out his own salvation. No amount of teaching can tell him how or when to make a professional call. He learns by experience; or if he have not the right make-up he never learns, always blunders and is a failure. But many fundamental principles as to the practice of the art could be imparted to students, that would tend to broaden their views as to their life work, make it appear more as a profession and less as a trade, save them from many serious mistakes and perhaps save them from that disastrous termination of many a brilliant career, the degradation into a sordid money maker. At least an elective course, consisting of lectures by a competent man, should be given in every college, to afford to the student the opportunity of learning concerning these matters that are of such practical importance. In addition to the subjects referred to by our correspondent such topics might be considered as the ethics of medicine, fees, that curse "commissions," medical societies, medical literature, malpractice, the physician's recreation, etc. Some colleges provide one or more lectures, but none, so far as we know, recognizes the importance of such a course of lectures.

### DOES INGESTED FORMALDEHYD HARDEN THE LIVING TISSUE?

WEBB CITY, MO., Jan. 13, 1904.

*To the Editor:*—Considering the well-known effect of formaldehyd hardening tissues, the question of the action of the drug on the epithelium of the kidney tubules following the administration of remedies containing the drug suggests itself to me. Has there been any report showing the effect, as found postmortem, on the kidneys of patients who have, during life, taken urotropin, formin, cystogen or other preparations containing formaldehyd?

L. C. CHENOWETH.

ANSWER.—So far as we know, there have been no reports to show that urotropin, etc., cause any permanent changes in the kidneys. The exact place in the urinary tract where urotropin forms formaldehyd does not seem to be known definitely. It may be that the formaldehyd does not have the chance to act as such on the cells of the kidney. Then, again, the dilution may be so great that while the antiseptic properties are still apparent, yet no cellular and reactive changes are produced. Investigations on persons who have habitually used foods, etc., preserved by formaldehyd may be of value. The Department of Agriculture experiments on humans under Dr. Wiley's supervision may add some facts. Coleman (*Med. News*, Aug. 29, 1903.) has collected and reported a number of cases of temporary toxic effects, strangury, hematuria, gastric and intestinal disturbance, etc., following the use of urotropin, which he attributes to idiosyncrasy, interference with the usual disposition of the formaldehyd in the body, or in the liberation of an unusual amount of formaldehyd. In all the cases the discontinuance of the drug was followed by rapid disappearance of the symptoms, which were altogether exceptional. Toxic effects from the drug as ordinarily given are very rare.

### INFANT DEATH RATE AND SCHOOL HYGIENE

SIOUX CITY, Jan. 21, 1904

*To the Editor:*—1. Can you give me the death rate of children from birth to at least three years old, especially where the cause is mostly due to feeding? Or what proportion of all children born die before the third year is reached? 2. Can you refer me to some article on ventilation of public schools? MILTON DAILY.

ANSWER.—1. The average death rate of children, as given in Newsholme's "Vital Statistics," varies from about 100 to 300 per thousand births in the different countries during the first year of life. The "Vital Statistics Report" of the United States Census Bureau gives the death rate for the year 1900 in the first year of life as 103.2; and 85.3 added to this number during the second and third years make a total of 278.5 under three years of age per thousand of population. The registration area in this country, however, is so small and the vital statistics so imperfectly reported through the greater portion that this can not be taken as the actual average for the whole. The death rate of children under three years of age would probably average not less than 250, and possibly higher for the first three years of life. The fact that the registration areas include the large cities where infant mortality is high must be considered.

2. We know of no recent article especially devoted to school ventilation; various works, like that of Morrisson's, published in 1887, are to be had through any book seller. But the subject is treated of in general works on hygiene like Chapin's "Municipal Sanitation," Egbert's "Hygiene," etc.

### LITERATURE ON ILLEGITIMACY.

CHICAGO, Jan. 23, 1904

*To the Editor:*—In answer to the inquiry of J. E. D. of Detroit (THE JOURNAL, Jan. 23, p. 256), I beg leave to state that the most satisfactory treatise on illegitimacy is the little book of Leffingwell (E. H. Colegrove, 65 Randolph St., Chicago. Price, $1.00.) He shows, much to the surprise of the casual observer, that illegitimacy prevails in certain sparsely settled, mountainous districts of Scotland to a greater extent than elsewhere in the world. His explanation, that the inhabitants are the descendants of pirates and that hereditary influence is the etiologic factor, has never been satisfactory to me. I have always maintained, and my views have been pretty generally upheld by sociologic students of experience, that there is a more likely explanation. The absence of prostitutes in these districts, the inadequate knowledge of sex relationship, which unfortunately is almost universal, and the misdirection, through faulty or deficient education, of the domination of the sexual instinct on the part of the male, are, to my mind, factors of chief importance in the consideration of illegitimacy.

DENSLOW LEWIS.

### THE ETHICS OF REPORTING AN IMAGINARY OPERATION AS HAVING BEEN PERFORMED.

HUMBOLDT, TENN., Jan. 18, 1904.

*To the Editor:*—Is a physician justified, under any circumstances, in writing an article for a medical journal in which he asserts that he has performed an operation, giving technic and results, when in fact he has performed no such operation, but has only conceived the idea that the operation would be applicable to the condition stated? Please publish this with your reply in THE JOURNAL for the benefit of any who may be concerned. Yours in the interest of science and truth. SIDNEY THOMPSON, M.D.

ANSWER.—We do not know to what article our correspondent refers, but his question seems to be answered in the asking.

### TRAINING SCHOOL FOR MALE NURSES.

DR. N. N. SALLUME, Toledo, Ohio, inquires where there is a hospital or other institution where male nurses are trained.

## Marriages.

GIOVANNI B. BRUNO, M.D., to Miss Marie Lagorio, both of Chicago, January 18.

HENRY CLAY GEMMILL, JR., M.D., Indianapolis, to Miss Helen Bringhurst of Philadelphia, January 12.

HUGH C. BEAZLEY, M.D., Bowling Green, Ky., to Miss Carrie B. Redd of Hopkinsville, Ky., January 20.

SAMUEL L. EDWARDS, M.D., Memphis, Tenn., to Miss Lillian Urbansky, at St. Marys, Kan., January 6.

HOWARD DAVIS LEWIS, M.D., Baltimore, to Miss Katherine Gray Blackshire, at Baltimore, January 14.

U. S. GRANT SPARKS, M.D., to Miss Kate Garuch, both of Mantua, N. J., at Camden, N. J., December 19.

GEORGE ARCHIBALD HOGAN, M.D., Bessemer, Ala., to Miss Myra Clark Gaines of Northport, Ala., January 27.

JAMES H. BANKS, M.D., Lincoln, Ill., to Miss Maude M. Wendell of New Holland, Ill., at Lincoln, January 13.

ROBERT W. COCHRAN, M.D., Madison, Ind., to Miss Leonora Livingstone Howard of Johnson City, Tenn., January 12.

## Deaths.

### EDMUND ANDREWS, M.D.

Dr. Edmund Andrews, scientist, pioneer in surgery and in medical education in the west, and student to the end of his life, died in Mercy Hospital, Chicago, January 22, aged 79.

EDMUND ANDREWS, M.D.

He was born in Putney, Vt., April 22, 1824, and there and in Rochester, N. Y., received his preliminary education. He was from the first devoted to botany and geology. At the age of 17 his family moved to central Michigan, and he entered the University of Michigan, Ann Arbor, where his work in mathematics and natural science was especially notable. He was also honored by being made president of his college literary society, and was graduated with the degree of B.A. in 1849.

He entered the office of Dr. Z. Pitcher, Detroit, in 1850, and attended lectures in the Medical Department of the University of Michigan. At the end of his first year he was made demonstrator of anatomy; received his degree in medicine in the following year, 1851, and was then made lecturer in comparative anatomy. By honesty, care and system he dispelled the common apprehension regarding dissections while occupying this position. He received his degree of master of arts in 1852 from the university, and two years later was made professor of comparative anatomy. He was one of the founders of the Michigan State Medical Society, and in 1853 began the publication of the *Peninsular Journal of Medical and Collateral Sciences.*

In 1855 he was appointed demonstrator of anatomy in Rush Medical College, but resigned after one year and devoted himself to practice, especially to surgery. Soon after his arrival in Chicago he aided in founding the Chicago Academy of Science, and was its first president, serving several times in this capacity. A short time after this he, in connection with Dr. Horace Wardner, established a charity dispensary, and a private dissecting room, where he taught a class in anatomy. He was one of the founders of the Chicago Medical College, and was its first professor of surgery. This latter position he held actively or emeritus up to the time of his death. He was also surgeon to the Mercy Hospital. When the Civil War broke out he was made surgeon of the First Illinois Light Artillery, but after a year was obliged to resign by reason of illness incurred in the service. He was the first to make and keep complete medical records of the sick and wounded in war, and his records were accepted by the surgeon general and formed the basis on which records of that office have since been kept. He was a pioneer in practical antisepsis, and was the first man in the west to employ Lister's method after its exploitation.

He was for many years a member of the American Medical Association, Michigan State Medical Society, Illinois State Medical Society, the Chicago Medical Society, the American Association for the Advancement of Science, the Chicago Academy of Science, Wisconsin Academy of Science, etc. For a number of years he was a trustee of Northwestern University. He contributed largely to medical literature. He collected and published statistics of 92,815 cases of ether anesthesia and 117,078 cases of chloroform anesthesia, showing the relative risk in the use of these two agents.

He was a lifelong member of the Presbyterian church, and a constant contributor to religious periodicals, his chief topic being the harmony of science and religion.

Although he had suffered from enlarged prostate and cystitis for two or three years he attended to his professional work until the day before he went to the hospital for operation. A vesical calculus was discovered January 13, and was removed three days later. He reacted well from the operation, and had been able to move about the room for three days when, on January 22, he had a sudden attack of vertigo, and was assisted back to his bed by the nurse. He had embarrassed respiration, which was relieved by oxygen, but, notwithstanding all efforts, he died in about an hour.

Outside of his work in medicine, Dr. Andrews was a geologist of repute, and his work on the early glacial history of North America has been very largely quoted. His papers on geologic subjects have been published in the Proceedings and Transactions of the Chicago Academy of Science and in Silliman's Journal. Dr. Andrews was one of America's great surgeons, not only by reason of his skill, but also because of his quick perception and adoption of improved methods. Dr. Andrews was married in 1850 to Miss Eliza Taylor of Detroit, who died in 1875; in 1877 he married her sister, Mrs. Frances M. Barrett, who survives him. He leaves two daughters and three sons, two of the latter, Drs. E. Wyllys Andrews and Frank T. Andrews, being of the medical profession.

---

**Nels N. Glim, M.D.** Hamline University, Minneapolis, 1898, a member of the American Medical Association, and secretary of the Ashland County (Wis.) Medical Society, died at Ashland, January 15, from general peritonitis following acute perforative peritonitis, for which operation was performed January 5.

**William H. Ireland, M.D.** University of Pennsylvania, Philadelphia, 1867, some-time president of the Camden city and county medical societies, and a life member of the state medical society, died at his home in Camden, N. J., from pneumonia, January 12, aged 60.

**Jefferson Williamson, M.D.** Cleveland Medical College, 1852, one of the founders of Wapello County Medical Society, died at his home in Ottumwa, Iowa, January 16, aged 76. The county society, at a special meeting, passed resolutions of eulogy and regret.

**Henry Plummer, M.D.** Medical College of Ohio, Cincinnati, 1861, died suddenly in his office in Harrodsburg, Ky., January 20, from heart disease. He had served as president of the Central Kentucky Medical Society and of the Mercer County Medical Society.

**Pollock F. Hyatt, M.D.**, died at Jersey Shore, Pa., January 17, aged 68. During the Civil War he was surgeon of Carver Hospital, Washington, D. C., and for five years prior to the Spanish War he was United States consul at Santiago, Cuba.

**Frederick Follett Comstock, M.D.** Bellevue Hospital Medical College, New York, 1873, health officer of Ilion, N. Y., for several years, died at his home in that village, January 12, from Bright's disease, after an illness of six weeks, aged 54.

**Alexander Douglas Bryden, M.D.** Indiana, 1898, assistant surgeon, U. S. Army, in the Spanish-American War, of Honesdale, Pa., died at the home of his brother in Carbondale, Pa., January 13, from nephritis, after a long illness, aged 35.

**Hugh Hendrixon, M.D.** Cleveland Medical College, 1870, of Columbus, Ohio, a member of the American Medical Association, died at Grant Hospital in that city, January 18, from cancer of the stomach, aged 70.

**Edmund S. Hanna, M.D.** Jefferson Medical College, Philadelphia, 1853, for many years a practitioner of Pittsburg, Pa., died at his home in East Orange, N. J., from apoplexy, January 17, aged 76.

**Benjamin G. Dysart, M.D.** Jefferson Medical College, Philadelphia, 1859, formerly brigade surgeon in the Confederate service, died at his home in Paris, Mo., January 17, from pneumonia, aged 70.

**Sydney Smith Thomas, M.D.** Toronto University Medical College, 1868; Bellevue Hospital Medical College, N. Y., 1872, died at his home in St. Anne, Ill., January 20, from uremia, aged 66.

**Samuel T. Purcell, M.D.** Homeopathic Medical College of Missouri, St. Louis, 1866, died at his home in Glasgow, from hemorrhage of the lungs, January 7, after a short illness, aged 80.

**Francis Woodley Harrell, M.D.** University of Maryland School of Medicine, Baltimore, 1879, Baltimore, died in New York City, January 19, from double pneumonia, aged 44.

**Schuyler C. Elliott, M.D.** Homeopathic Hospital College, Cleveland, 1886, died at his home in Kansas City, Kan., from paralysis, after a short illness, January 14, aged 39.

**John W. Martin, M.D.** College of Physicians and Surgeons, Baltimore, 1890, died at his home in Unionport, Ohio, January 10, from tuberculosis, after a long illness, aged 40.

**Royal H. Hardman, M.D.** National Medical College, Washington, D. C., 1897, died suddenly at his home in White Earth, N. D., January 12, from heart disease, aged 36.

**A. Tennyson Sanders, M.D.** Medical College of Ohio, Cincinnati 1897, died, January 11, at his home in Leesburg, Ohio, from Bright's disease, after a lingering illness.

**Robert E. Jenkins, M.D.** Louisville Medical College, 1898, died at his home in Belmont, N. C., January 9, from typhoid fever, after an illness of two weeks, aged 28.

**E. R. Manning, M.D.** Missouri Medical College, St. Louis, 1897, local surgeon of the Texas Central Railway, died at his home in Stamford, Texas, January 14.

**John H. Ginley, M.D.** Homeopathic Hospital College, Cleveland, 1862, died at his home in Coopersville, Mich., January 18, after an illness of one week, aged 75.

**Rachel A. Dickey, M.D.** Woman's Medical College of Pennsylvania, Philadelphia, 1867, of Philadelphia, died in New London, Md., January 3, aged 79.

**James Porter Henry, M.D.** Transylvania University, Lexington, Ky., 1843, died at his home in Independence, Mo., January 13, after a short illness, aged 84.

**John Frank Lyngar, M.D.** Missouri Medical College, St. Louis, 1875, died at his home in Greenfield, Mo., January 14, from heart disease, aged 60.

**George Perry Cook, M.D.** New York, 1846, once assistant physician at Bloomingdale Asylum, died in Brattleboro, Vt., January 3, aged 83.

**H. K. De Armond, M.D.**, of Huntersville, N. C., died at the home of his daughter in Mount Gilead, N. C., January 10, from paralysis, aged 82.

**John H. Scally, M.D.** College of Physicians and Surgeons, Baltimore, coroner of Baltimore County, died at Towson, January 21, aged 33.

**Joseph Marshall Staunton, M.D.** Geneva (N. Y.) Medical College, 1857, died at his home in Charleston, W. Va., from uremia, aged 84.

**Lycurgus A. Dickson, M.D.** Jefferson Medical College, Philadelphia, 1855, died at his home in Desha, Ark., January 19, from paralysis.

**Harvey B. Godfrey, M.D.** University of Minnesota, College of Medicine and Surgery, Minneapolis, 1902, of Black Duck, Minn., died recently.

**Joseph C. Ridings, M.D.** St. Louis Medical College, 1872, of Cairo, Mo., died in an epileptic seizure at Kansas City, Mo., January 15.

**Ernest S. Foster, M.D.** Washington University School of Medicine, Baltimore, 1869, died at his home in Louisburg, N. C., January 11.

**Margaret G. Coleman, M.D.** Penn Medical University, Philadelphia, 1858, died at her home in Williamsport, Pa., January 9, aged 82.

**Henry C. Ahlborn, M.D.** New York Homeopathic Medical College and Hospital, 1866, died at his home in Boston, January 9, aged 79.

**Simeon Deming Hart, M.D.** Ohio Medical College, Cincinnati, 1844, died at his home in Marietta, Ohio, January 21, aged 85.

**Frederick Kuithan, M.D.** University of Berlin, Germany, 1853, died, January 14, at his home in Nauvoo, Ill., aged 70.

**Charles P. White, M.D.** Howard University, Washington, D. C., 1898, died at his home in Richmond, Va., November 16.

**Samuel D. Coffin, M.D.** Miami Medical College, Cincinnati, died at his home in Whittier, Cal., December 25, aged 77.

**Thomas J. Ketchum, M.D.** Castleton (Vt.) Medical College, 1847, died recently at his home in Pittsford, Vt.

**John K. Patterson, M.D.** Jefferson Medical College, 1868, died at his home in Philadelphia, January 14.

**John M. Kauffman, M.D.**, retired, died suddenly, January 11, at his home in Winchester, Va., aged 70.

**Perry McElvain, M.D.** Illinois, 1877, died at his home in Alto Pass, Ill., Nov. 13, 1903.

### Death Abroad.

**F. Jolly, M.D.**, director of the clinic for nervous and mental affections at Berlin, died there, January 4, aged 59. Death was due to perforation of an aneurism into the pericardium, in the midst of apparent health.

## Miscellany.

**Von Behring's Research on Milk for Infants and Prevention of Tuberculosis: Correction.**—In the abstract on page 277 with the above title in THE JOURNAL of Jan. 23, 1904, the reference to previous communications from von Behring should have read: See previous articles in THE JOURNAL, xl, pages 1178 and 1266, and xli, pages 814 and 994.

**Some Effects of Tobacco.**—J. A. Henton White reports several cases in which the poison from smoking produced symptoms which were concentrated on either the respiratory, the cardiac, or the alimentary system. These exaggerated symptoms all occur in a modified form in seasoned and seasoning smokers who exceed their dose. They also all point to there being such a condition as hereditary incapacity to smoke. In subjects whose alimentary canal is upset, the pain is described as being of a peculiar grinding character. Neuralgia of the thoracic and humeral varieties is another symptom, produced especially by Havana cigars, whether these symptoms are due to a neuritis or a more central affection is disputed—possibly both may occur together or separately.—*Birmingham Medical Review.*

**Cataract from Iodin Intoxication.**—Dr. G. Corda of Pisa describes, in the *Annali di Ottalmologia*, xxxii, 5-6, 1903, a case of intoxication from the use of potassium iodid taken on account of a tendency to obesity. The patient was a mechanic, 43 years old, always robust, and the amount ingested in the course of seven days was only 1.5 gm. The third day he noticed pains in the soles of the feet, extending into the legs, and by the seventh day he was affected with lachrymation, photophobia and spasmodic closure of the lids, with a cataract-like formation in both eyes, like a semi-transparent disc in the center, which explained the dimness of vision accompanying the blepharospasm. On suspension of the drug the symptoms rapidly subsided and vision was normal again by the end of a week or two. [In the case of cataract formation after the use of naphthalin, reported in THE JOURNAL, xxxix, p. 926, 1902, the zonular cataract did not subside after the suspension of the drug, but persisted with vision much reduced.—ED.]

**Dangers from Lightning.**—The *Gazette Méd. de Paris*, in an editorial, October 27, discusses the loss of life from lightning in recent years and prophylactic measures. The annoyance from the rain during a thunder storm is a concrete evil, while the danger from lightning is problematic, consequently individuals will probably continue to seek shelter under trees in the future as in the past, notwithstanding the warnings of the profession. But at least they can scatter and not all huddle under one tree. The human body is a good conductor for electricity, and this attraction, plus that of the tree, is increased by the mass of bodies grouped at one spot. Another point to be borne in mind is to refrain from bringing farming implements, guns, swords, etc., under the same tree under which the bearer is sheltered. In any event they should not be retained in the hand. It is a familiar experience that four-footed animals are injured more severely by lightning as a rule than bipeds, human or others.

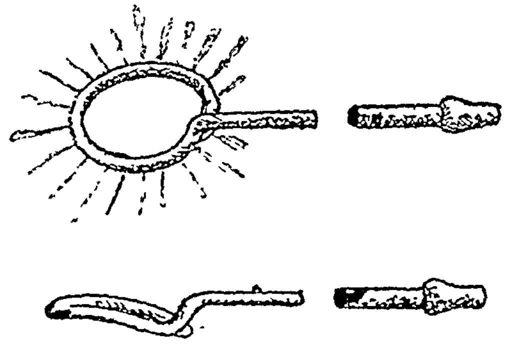
**Transient, Relative Aortic Insufficiency.**—Popoff has observed a number of cases of insufficiency of the aortic valves accompanied by weak and accelerated heart action with a tendency to aneurismatic dilatation of the aorta, in which the symptoms subsided and even entirely disappeared as soon as the heart action was regulated and the dilatation of the aorta diminished. In the *St. Petersb. Med. Woch.*, xxvii, 45-7, he says the insufficiency may be of the valves or of the ostium, and may be transient or chronic, the former the precursor of the latter unless cured. It is extremely important to be able to differentiate the transient form and institute proper treatment. The inconstancy and changeability of the sounds must not mislead the clinician suggesting a pericarditis or other affection. Treatment must be directed to the underlying arteriosclerosis and the cure of the tendency to aneurismatic dilatation, as also of the conditions which have entailed extra work on the heart, bronchial affections causing severe coughing, etc., gastrointestinal autointoxication, constipation, leading to upward pressure of the diaphragm and efforts in defecation, and all factors that bring over-fatigue of mind or body, or cause disturbances and weakening of the heart action, congestion in the aorta, etc.

**Non-Surgical Treatment of Rupture of the Uterus.**—Privat docent D. Popoff advocates leaving to Nature the task of repairing the rupture and describes two cases treated on this principle. The necessity of transporting the woman to a hospital is thus avoided. Both his patients were about 32 years old and working women, multiparæ. The rupture was complete in each case and was treated by immobilizing the uterus by pressure on the abdomen, forcing it down and thus favoring healing of the rupture. In one case iodoform gauze was inserted in the vagina and in the other a strip was worked up behind the point of the rupture to prevent prolapse of the intestines and omentum, with care not to allow any of the gauze to interpose between the lips of the wound. In order to avoid manipulations in the abdomen he was obliged to perform decapitation of the fetus in one case. The patients were dismissed quite restored to health, the twenty-ninth and thirty-first days. The healing proceeded without fever and without any therapeutic measures in the first case; in the other there was slight temperature the seventh day only, and a few hot douches were given on account of a plastic exudate noted on the tenth day. Klien states that the mortality was only 25 per cent. in 12 cases of rupture in the posterior wall which he has collected, while it was 60 per cent. in 15 cases of rupture of the anterior wall, 49 per cent. in 35 cases of lateral, and 40 per cent. in 5 of almost circular rupture. The length of time that has elapsed before treatment is commenced is an important factor for the prognosis of the cases operated on, but this can usually be disregarded in case of non-operative treatment. If the operation is undertaken in the first two hours the results are most favorable; after this period the mortality is twice or thrice as high. His communication in the *Allg. Med. Ct.-Ztg.*, lxxii, p. 440, is a careful study of the entire subject.

**Improved Technic of Extracting Foreign Bodies from the Brain.**—Dr. G. Holzknecht of Vienna, the expert for medicolegal *x*-ray cases, announced at his local medical society, June 19, that he has devised a method by means of which a foreign body in the brain can be extracted as easily as a pebble can be taken out of a glass of water. He remarks that fifty different methods of locating foreign bodies in the brain have been published, but none to date have proved infallible. By his method the patient is examined with two Roentgen tubes, one under his head as he lies on the operating table, and one at the side. After the foreign body has been carefully located with the first tube a small flap of periosteum and bone is cut and raised, care being taken to have this flap made at the most accessible point where such a flap and the following procedures will do the least injury. The patient is then arranged so that the shadow of the foreign body falls in the exact center of the flap. A pair of special forceps are then mounted in the "harpoon forceps" and applied to the skull in such a way that the shadow of the forceps falls in the center of the flap as a mere point, thus coinciding with the shadow of the foreign body. The instrument is then inserted into the brain on this same axis, to the point where the foreign body is supposed to lie, its progress controlled by the shadows cast by the second Roentgen tube, which is lighted up for the purpose. He has found that with a good technic it is possible to see in this way shot or fragments as small as 1 mm. in diameter, and with a little practice, to feel the contact of the forceps with the foreign body. The instrument is inserted on the path which the foreign body must follow in being extracted, and if the foreign body is not wider than the diameter of the narrow forceps no further damage is done.

**Silicosis.**—Dr. George T. McWhorter, Riverton, Ala., delivered an address before the faculty and students of the Medical Department of the University of Alabama, at Mobile. The Mobile County Medical Society was also invited, and many members attended. The subject was "Silicosis," and the paper described an epidemic of the disease among the workers in a factory near Riverton, where pure, white silica is reduced to an impalpable powder for use in the arts, especially for the glazing of fine porcelain. Every object within the building and within a large radius outside was covered with the white dust. Trees, shrubbery and grass seemed covered with snow. From a tall chimney intended to carry the dust away a cloud arose that resembled white steam, and trailed away into the distance, depositing the microscopic, gritty particles in every direction at the veering of the wind. In this dusty atmosphere twenty-six working people were employed. Within two years sixteen were dead and two more in bad health, with symptoms similar to those of the fatal cases. The history of the remaining eight is unknown. Dr. McWhorter saw ten of the fatal cases, and was credibly informed that the others were similarly affected. He stated that there was no necessity for the murderous process that had proved so fatal at that place, as there was a wet process which absolutely removes all danger. Silica is not poisonous in any sense of the term, but its particles, however small, are too irritating to delicate mucous membranes for permanent contact to be wholesome. Tuberculosis was not present in any of these cases, though the irritated bronchial membranes would have provided a favorable nidus for the tubercle bacilli had they been present in the atmosphere. Riverton is not a town, but merely a postoffice, with a few stores and residences at long intervals, and its other conditions aid in rendering a tubercle infected atmosphere almost impossible. There were no night sweats or hectic fevers, no hemorrhages or other symptoms of tuberculosis.

**Continuous Irrigator for Treatment of Ophthalmia Neonatorum.**—Prof. A. Galiani of Salerno, Italy, thinks that the ravages of this affection are due in many instances to inadequate treatment. He believes that the eye should be cleansed every fifteen to twenty minutes in the first acute stage, and he has invented a little apparatus for the purpose. As seen by the illustration it is a loop of silver tubing, perforated around the edge and shaped like the edge of an artificial eye to fit deep into the conjunctival culs-de-sac. It is easily inserted into the eye and the swollen lids hold it firm. A rubber bulb is filled with physiologic salt solution and the connecting tube attached to the projecting end of the silver tube. By compressing the bulb the fluid is all forced out into the eye. It escapes where the lids are slightly lifted by the entering tube. The rubber tube and bulb are then removed and the silver tube left in place all day, the irrigations being repeated every fifteen to twenty minutes. A bayonet catch fastens the rubber tube and the parts together. Every two hours he substitutes a weak solution of phenic acid for the salt solution. The presence of the tube in the eye does not cause any irritation and does not interfere with external application of tepid compresses. In the evening the silver tube is taken out and sterilized by boiling. After two or three days the swelling of the lids subsides, the secretion is materially diminished and the infant commences to open its eyes. The tube is then discarded and 2 per cent. silver nitrate instilled morning and night. The use of this continuous irrigator will certainly prevent damage of the cornea if applied in time, but if first seen too late the irrigator should be used until the secretion has nearly entirely subsided. He concludes his description of the apparatus in the *Annali di Ottalmologia*, xxxii, 7-8, 1903, by recommending it particularly for diplococcus conjunctivitis with lesions of the cornea.



**The Painful-Point Theory and Treatment of Nervous Gastro-Intestinal Disturbances.**—Dr. Cornelius of Meiningen proclaims that in every case of purely nervous gastro-intestinal disturbances it is possible to discover one or more peripheral points which are painful on pressure and which explain the syndrome observed. He has been able to cure them by massage of these painful points, and also to induce the disturbances by manipulation of the painful points during an interval of calm. Pressure on these painful points may induce a nervous diarrhea in certain subjects, hemorrhage from hemorrhoids, or severe gastro-intestinal disturbance. In treatment he seeks for these painful points in the interspaces and over the abdomen, and when found he massages and manipulates them until they cease to be painful, when the troubles they have been causing will also disappear. He differentiates the painful point from an inflammatory process by the response to the application of cold which soothes the latter but increases the irritation in the purely nervous cases. Cornelius read a summary of his views at the last Naturforscher Congress, and his communication is published in full in the *Klinisch-therap. Wochft.*, Nos. 35 and 41, 1903. He has established seven laws that govern these painful points, including the law that when the pain from a point radiates in a certain direction another painful point will be discovered at the end of the radiation. Also that mechanical treatment of a painful point will invariably banish its sensitiveness and with it the pain which emanates from it. The paroxysms of pain which manifest themselves at these painful points may be the result of any one of a number of stimuli originating within or out of the organism and not necessarily a pathologic irritation. He attributes the painful points to some induration or cicatrix left by some external or internal affection, which injures or compresses the nerve. The nervous strain of our civilization tells in time on these points of lessened resistance. Massage at these points restores them temporarily or permanently to normal and they no longer interrupt the course of the nerve current. Treatment should aim to soothe the over-excited nervous system as a whole and to mechanically smooth out the "knots" in the nerve.

# Book Notices.

The Practice of Obstetrics. Designed for the Use of Students and Practitioners of Medicine. By J. Clifton Edgar, Professor of Obstetrics and Clinical Midwifery in Cornell University Medical College. With 1,221 Illustrations, Many in Colors. Cloth. Pp. 111. Price, $6. Philadelphia: P. Blakiston's Son & Co. 1903.

This book is the most pretentious work on obstetrics issued in English in recent years; in many respects it is encyclopedic in character. From Edgar's long experience as a teacher, and his originality in producing many of our best models and devices for practical obstetric pedagogy, we might expect to find much of his inventive genius exemplified in his book. Its scope is broad; the refinement of classification under appropriate headings so extensive that it may well serve as an invaluable reference volume for the practitioner. We feel that so much is embodied within its pages that it is not so suitable for student reading as other smaller text-books on the same subject. The volume is divided into ten parts and an appendix; each part is divided into numerous subdivisions, which again are divided by many subheadings. The subheadings offer a ready means of reference, and in nearly all instances unquestionably enhance the clearness of the subjects. We would call attention to certain topics, however, which are, to our mind, injuriously affected by the classification before us. In the part devoted to "Physiological Labor" we find "Occiput Posterior" discussed under the subdivision of "Vertex Presentations"; under "Pathological Labor," subdivision "Faulty Position," we find "Persistent Occiput Posterior"; again, in the part devoted to "Pathological Labor," under the caption of "Faulty Attitude," we find the discussion of brow and face presentations, and Naegele and Litzmann's obliquities; under "Fetal Dystocia from Faulty Position," we find "Persistent Mentoposterior Position." We think this arrangement implies too strongly that the several forms are distinct obstetric entities, while in reality they are but aberrancies from the normal mechanism for the several presentations. This interferes considerably with the sequence of thought. We believe that a complete exposition of the subjects of occiput posterior, brow, face, etc., more lucidly and more comprehensively could be included under their appropriate headings. In the same manner we feel that perineal lacerations should receive their operative consideration in direct sequence to the discussions of their cause and prophylaxis. While we dissent to the arrangement in parts, too high praise can not be accorded to most of the chapters—the handling of the subjects is judicious, practical, and with the conservatism needed in a work for the general practitioner and student. We can not too strongly commend the careful scientific discussions of the following subjects, which are yet eminently practical: the diagnosis of pregnancy, the calculation of the probable date of confinement when data are wanting, which is germane to the sections dealing with fetometry. The section on cephalometry includes the methods of Ahlfeld, Perret, Dubois, Müller, and the use of the Roentgen ray, which are adequately stated, and, so far as known, have not collectively appeared in American text-books on obstetrics. The investigation of the pregnant and parturient woman by palpation, mensuration, auscultation and inspection is fully given. The complete elucidation of the subject of pelvimetry very appropriately is given under the routine examination of the pregnant—to relegate this most important subject to the consideration of contracted pelves implies that such measurements are essential only in dystocic conditions, whereas their true value may be adduced by the obstetrician only when he uses pelvimetry as a routine. The discussion of obstetric surgery is fully represented by all the modern operative procedures; the technic for each operation is fully described. The book is replete with illustrations, most of which are new and truly illustrative of the text. Many of the cuts are accompanied by a schematic drawing which depicts in detail the companion picture. These are interspersed freely through the volume, but are especially instructive in the purely clinic illustrations, as are also those showing the details of the mechanisms of labor. A very few cuts might well be dispensed with in succeeding editions, e. g., pictures of the containers of chlorid of lime and baking soda; the representation of an ordinary glass catheter which well could be replaced with a picture of the details of an aseptic catheterization; *en' passant*, it would be well to call attention to the grave danger of the use of a glass catheter during labor. As this book is a work pre-eminently for collateral reading, its value would be greatly enhanced if a full reference list of the literature were appended in subsequent editions. The work of the illustrator has been unusually good, as is the typographical make-up; the binding, however, is wretchedly poor, a serious fault in a reference book, which this is supposed to be.

Aromatici e Nervini. Nell'Alimentazione. I Condimenti, L'alcool (Vino, Birra, Liquori, Rosolii, ecc.); Il Caffè; Il Thè; Il Guarana; La Noce Di Kola, ecc. Sull'Uso Del Tabacco da Fuma e da Fiuto. By Dott. Adriano Valenti, Dell'Instituto Farmacologia Della R. Universita di Pavia. Cloth. Pp. 64. Milano: Ulrico Hoepli. 1904.

This is another of the convenient little Hoepli manuals; it appears to cover its subject of neurotic drugs and beverages fairly well. The larger portion of it is given to the subject of alcohol, on which the author's opinions are conservative. He remarks that it is not a direct food, but is a systemic poison, but that in its milder diluted forms it is of use. He would, however, forbid or restrict its use by women and youths. Other substances are also treated in more or less detail, and the work reviews the physiology of aromatic and nervine drugs in a general way. To one familiar with Italian, it will be a convenient little reference work. A curious fact is that the author has apparently not got hold of Atwater's researches, though he quotes Chittenden, and the book, therefore, is not absolutely up to date, but in other respects it seems to be a satisfactory treatise for its compass.

A Manual of Surgical Treatment. By W. Watson Cheyne, C.B., M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London, and F. F. Burghard, M.D., M.S. (London), F.R.C.S., Teacher of Practical Surgery in King's College, London. In Seven Volumes. Volume VII. The Treatment of the Surgical Affections of the Rectum, the Liver, Pancreas and Spleen, the Genito-urinary Organs, the Breast and the Thorax. Cloth. Pp. 559. Price, $5.75 net. Philadelphia and New York: Lea Brothers & Co. 1903.

Volume VII completes a very extensive work, previous volumes of which have already been mentioned in these columns. This volume, whose field is outlined above, is one of the best of the series. It follows the general plan of dealing chiefly with the subject of treatment and the methods described are those which the experience of the authors approves. Special attention is given to details of after-treatment. A complete index of the work would have been a very desirable addition. As it is, one must consult the index of each volume until the subject sought is found. The work abounds in practical matter, and is one of which the authors may well feel proud.

A Compend of Pathology, General and Special. A Student's Manual in One Volume. By Alfred Edward Thayer, M.D., Professor of Pathology, University of Texas. Second Edition, Containing 131 Illustrations. Leather. Pp. 711. Price, $2.50. Philadelphia: P. Blakiston's Son & Co. 1903.

This work is a second edition of two previous compends on pathology by the author, and includes a new chapter on the nervous system and several additional illustrations; a general revision has also been made. The treatment of the subjects is, naturally, brief, but the illustrations are numerous and the text is generally good. In a few instances, however, the definitions are rather brief, and might have been bettered in some respects; for instance, the author speaks of dementia paralytica as a "peculiar cortical lesion associated with gradual loss of memory," which gives a somewhat erroneous idea of the subject. Taken altogether, the statements are fairly clear. The make-up of the work, with its flexible binding and gilt edges, is excellent.

The Fifth Annual Report of the Indiana State Board of Medical Registration and Examination for the Year Ending Dec. 31, 1902. Cloth. Pp. 270. Indianapolis: Wm. B. Burford. 1903.

The Indiana board has issued its official register of physicians, together with its state laws and a summary of the laws of other states. The book is well arranged, and seems to contain all the information that can be asked on the subjects. It is a state document, published under authority, and may, therefore, be considered official. It has evidently been compiled with great care, and is a valuable reference work not only for Indiana physicians, but also for medical journals and others who have to do with the questions of medical registration and education outside of the state.

How to Attract and Hold an Audience, A Popular Treatise on the Nature, Preparation and Delivery of Public Discourse. By J. Berg Esenwein, A.M., Lit. D., Professor of the English Language and Literature in the Pennsylvania Military College. Cloth. Pp. 272. Price, $1.00. New York: Hinds & Noble.

The art of oratory and public speaking is one which the most of us think we can acquire without special care or training. How much we are mistaken in this many of us have to realize when we come to the actual trial. This little work aims to be suggestive, and the advice given is for the most part safe and judicious. The work will be of value to anyone who intends to engage in public speaking either as an amateur or in a professional way, and especially if only to meet an occasional call.

Doctor Joseph Leidy; A Portrait. Etched by James S. King, Newark, N. J. Engraved Surface 13½x16 Inches. Limited Edition of 150 Copies. Printed on Imperial Japan Vellum Paper and Signed by the Artist. Price, $15. Philadelphia: William J. Campbell.

The above is a very excellent reproduction of a portrait etched by King, and is well worthy of a place in any physician's office. The portrait represents the highest type of such work. Dr. Leidy was one of the leading figures among medical men of this country during the early and middle years of the nineteenth century, and left a name that was revered by all who knew him or his work, and such will be glad of an opportunity to obtain such an excellent portrait of him as is here presented.

Nurses' Guide to Surgical Bandaging and Dressings. By William Johnson Smith, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich. Cloth. Pp. 167. Price, $0.75. Philadelphia. J. B. Lippincott Co. 1903.

The size of this book is such that it can be put in the dress pocket (if nurses have such), but with the size of print it contains a large amount of information, much of which seems likely to be useful and valuable to nurses. The illustrations are instructive and the text is clear. Some of the information seems rather superfluous.

The Four Epochs of Woman's Life. Maidenhood, Marriage, Maternity, Menopause. By Anna M. Galbraith, M.D., Author of "Hygiene and Physical Culture for Women," Fellow of the New York Academy of Medicine. With an Introductory Note by John H. Musser, M.D., Professor of Clinical Medicine, University of Pennsylvania. Cloth. Pp. 247. Price, $1.50 net. Philadelphia, New York, London: W. A. Saunders & Co. 1903.

Dr. Galbraith has fairly satisfactorily treated this difficult subject as it may be described advantageously to lay readers. Her advice is practical and the book is to be recommended.

# The Public Service.

## Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ending Jan. 23, 1904:

McCulloch, C. C., Jr., Reynolds, Fred. P., Woodson, Robt. S., Hallock, H. M., Newgarden, Geo. J., Straub, Paul F., Stark, Alex. N., Lynch, Charles, and Kulp, John S., captains and asst.-surgeons, ordered to report in person to Major Wm. H. Arthur, surgeon, president of examining board for promotion, Army Medical Museum building, Washington, D. C., about March 14, 1904, for examination for promotion.

Chamberlain, W. P., asst.-surgeon, relieved from duty at Cabana Barracks, on withdrawal of troops from Cuba, and ordered to Manila, P. I., for duty.

Bevans, Jas. L., asst.-surgeon, relieved from duty at Morro Castle, Santiago, Cuba, on withdrawal of troops and ordered to Fort Barrancas, Fla., for duty.

Kirby-Smith, R. M., asst.-surgeon, relieved from duty at Fort Barrancas, Fla., and ordered to Manila, P. I., for duty.

Hansell, H. S., asst.-surgeon, relieved from duty at Fort Monroe, Va., and ordered to Manila, P. I., for duty.

Shockley, M. A. W., asst.-surgeon, having reported at San Francisco, en route to Manila, P. I., is assigned to temporary duty at Post Hospital, Presidio of San Francisco.

Stiles, Henry R., asst.-surgeon, order relieving him from duty in the Division of the Philippines, is revoked.

Woodson, Robert S., asst.-surgeon, granted two months' leave of absence about February 1.

Patton, I. W., asst.-surgeon, granted thirty days' leave of absence.

Enders, William J., contract surgeon, has been granted two days' leave on completion of duty at Fort Delaware, Del., before proceeding to his new station, Fort Morgan, Ala.

Baird, William T., contract surgeon, has been granted two months' leave of absence from Fort Bliss, Texas, to take effect about February 1.

## Navy Changes.

Changes in the medical corps of the Navy, week ending January 23:

Moore, A. M., surgeon, retired, detached from the Naval Recruiting Station, Chicago, and ordered home.

Wilson, G. B., surgeon, detached from the *Wabash* and ordered to the Naval Torpedo Station, Newport, and to additional duty in attendance on naval and marine officers.

Gardner, J. E., surgeon, ordered to the *Wabash*.

Lumsden, G. P., surgeon, detached from the Naval Torpedo Station and ordered to the Naval Recruiting and Marine Recruiting Stations, Chicago.

Wentworth, A. R., surgeon, detached from the *Albany* and ordered to the *Solace*.

Crandall, R. P., surgeon, detached from the *Wisconsin* and ordered to the *Oregon*.

Guest, M. S., P. A. surgeon, detached from the *Oregon* and ordered to the *Albany*.

Webb, U. R., asst.-surgeon, detached from the *Annapolis* and ordered to the Naval Station, Cavite, P. I.

Bishop, L. W., asst.-surgeon, detached from the Naval Hospital, Yokohama, Japan, and ordered to the *Annapolis*.

McClanahan, R. K., asst.-surgeon, ordered to the Asiatic Station via steamer sailing from San Francisco February 1.

## Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Jan. 22, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, Jan. 3-10, 3 cases.
District of Columbia: Washington, Jan. 9-16, 1 case.
Georgia: Darien, Jan. 15, 2 cases.
Illinois: Jan. 9-16, Chicago, 5 cases; Danville, 7 cases; Freeport, 1 case, imported.
Indiana: Evansville, Jan. 9-16, 4 cases.
Massachusetts: Lawrence, Jan. 9-16, 1 case.
Michigan: Grand Rapids, Jan. 9-16, 1 case.
New Hampshire: Nashua, Jan. 9-16, 1 case.
New Jersey: Trenton, Jan. 9-16, 7 cases.
Ohio: Jan. 8-15, Cincinnati, 3 cases; Cleveland, 1 case; Dayton, Jan. 9-16, 1 case.
Pennsylvania: Jan. 9-16, Johnstown, 1 case; Philadelphia, 58 cases, 24 deaths; Pittsburg, 8 cases, 3 deaths; Reading, Dec. 11-18, 1 case; Williamsport, Jan. 2-16, 2 cases, 1 death.
South Carolina: Charleston, Jan. 9-16, 4 cases.
Tennessee: Jan. 9-16, Memphis, 19 cases; Nashville, 2 cases.
Wisconsin: Milwaukee, Jan. 9-16, 34 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Dec. 26-Jan. 2, 6 cases, 1 death.
Brazil: Pernambuco, Nov. 15-30, 33 deaths; Rio de Janeiro, Dec. 6-20, 124 cases, 63 deaths.
Canada: New Brunswick, McAdam, Jan. 9, 1 case.
Great Britain: Dec. 26-Jan. 2, Birmingham, 1 case; Edinburgh, 3 cases; London, 4 cases; Manchester, 3 cases; Newcastle-on-Tyne, 1 case; Bradford, Nov. 21-Dec. 5, 1 case; Glasgow, Dec. 27-Jan. 8, 92 cases, 9 deaths.
Netherlands: Amsterdam, Jan. 2-9, 4 cases.
Russia: Moscow, Dec. 5-12, 1 death; St. Petersburg, Dec. 12-26, 58 cases, 1 death.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Dec. 6-20, 1 case, 1 death.
Jamaica: Kingston, Dec. 26-Jan. 2, 1 case, 1 death.
Panama: Panama, Jan. 2-10, 1 case, 1 death.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Dec. 6-20, 38 cases, 28 deaths.
India: Calcutta, Dec. 12-19, 15 deaths.

CHOLERA.

India: Calcutta, Dec. 12-19, 28 cases.
Turkey in Asia: Kerbela, Dec. 12, 50 cases daily.

# Medical Organization.

## Florida.

Duval County Medical Society.—At the recent annual meeting, this society reorganized on the standard plan, and elected the following officers: Dr. Robert H. McGuiness, president; Dr. Edward N. Liell, vice-president, and Dr. Jay H. Durkee, secretary and treasurer, all of Jacksonville.

## Illinois.

Ottawa (La Salle County) Medical Society.—This society reorganized, at its annual meeting, January 17, on the standard plan, and elected the following officers: Dr. Edmund W. Weis, president; Dr. James N. Downs, vice-president, and Dr. William A. Pike, secretary.

## Kansas.

Crawford County Medical Society.—This society was organized on the standard plan at Pittsburg, January 7, with an initial membership of 25. The following officers were elected: President, Dr. E. Orlando Sloan, Pittsburg; vice-president, Dr. Andrew J. Dodds, Fleming; secretary, Dr. Hugh B. Caffey, Pittsburg, and treasurer, Dr. Asbury C. Graves, Pittsburg.

### Maryland.

Progress.—County medical societies in affiliation with the Medical and Chirurgical Faculty of Maryland, which is the state society, have been formed in all but four of the counties. It is proposed to complete very shortly the work in these counties.

### Mississippi.

Jones County Medical Association.—Physicians of the county met at Ellisville and organized this association, with the following officers: President, Dr. Sidney O. Smith, Ellisville; vice-president, Dr. Henry G. McCormick, Laurel, and secretary and treasurer, Dr. Troy M. Sexton, Laurel.

### South Dakota.

South Dakota (Ninth District) Medical Society.—The physicians of the Black Hills district of Western South Dakota met at Lead, January 18, and organized on the standard plan, with the following officers: Dr. Adelbert H. Bowman, Deadwood, president; Dr. Charles W. Hargens, Hot Springs, vice-president; Dr. Alfred G. Allen, Deadwood, secretary; Dr. Frank S. Howe, Deadwood, treasurer, and Drs. G. Hayward Coburn, Deadwood, William W. Torrence, Deadwood, and John W. Freeman, Lead, censors.

## Society Proceedings.

### CHICAGO MEDICAL SOCIETY.

*Regular Meeting, held Jan. 20, 1904.*

The President, Dr. R. B. Preble, in the Chair.

### SYMPOSIUM ON DIETETICS.

#### The Dietetics of Atonic Dilatation of the Stomach.

Dr. Fenton B. Turck read this paper, in which he divided the mechanical work of the stomach into (1) distention with food; (2) expulsion, and (3) relaxation. He illustrated how increased tension or resistance, under some circumstances, causes atony and dilatation as the result of prolonged overwork and exhaustion of the gastric muscle, etc. In determining the exact regimen of dietetics in atonic dilatation, all symptoms and conditions must be subordinated to the one central indication, namely, the restoration of the exhausted gastric muscle; this effort is not only for the nutrition of the patient, but for the prevention of bacterial growth and the resulting toxins which produce many of the grave symptoms. It may be necessary to lessen the total amount of food for a period, and undernourish the patient, thus giving rest to the diseased organ at the expense of the whole organism. The gain here is twofold: First, food is better digested, and, second, it is not robbed of its nutritive value by bacterial growth.

Theoretically, a liquid diet is most advantageous; practically, finely divided solid food is best, properly prepared, with appropriate amount of liquid, sufficient to aid the stomach to macerate the mass and inject it into the intestines.

In connection with diet, lavage is often of value, as are also galvanic and faradic electricity, general baths, exercise and drugs.

#### Diet in Hyperchlorhydria.

Dr. B. W. Sippy, after describing the condition and its symptoms said that in the treatment of the condition diet is all-important; but etiology must be taken into account in each case. The following causes were mentioned: Hasty eating, improperly prepared food, overeating, certain ill-defined disorders of the nervous system, nervous shock, worry, fatigue, ulcer, alcohol and tobacco.

Fortunately, by close attention to diet alone most cases may be satisfactorily treated. The diet should fulfill the following indications: First, mechanical, chemical and thermal irritation of sensory and secretory nerves of the stomach by food and drink must be reduced to the minimum. Second, food should contain a liberal quantity of albumin to combine with the excessive hydrochloric acid. Third, the diet must be sufficiently nourishing. Fulfillment of indications is simple. All foods should be taken in a state of fine subdivision, and great care given to thorough mastication. Meat should be scraped or finely teased apart. Potatoes and all vegetables should be given in as near purée form as possible. Pickles, potato salad, fried potatoes, coarse nuts, radishes and similar coarse articles; also coffee, spices, sharp condiments, mustard, pepper, vinegar, acids and alcoholic drinks; also hot and cold food and drink should be avoided. The diet should be a mixed one. In the beginning of the treatment a liberal quantity of albumin in the form of lean meat should be given, because it is non-irritating and combines a maximum quantity of hydrochloric acid. Fat in the form of butter and cream is well tolerated, and tends to reduce the quantity of acid secreted. Because the excessive acidity quickly inhibits the action of the ptyalin, the starches should be restricted moderately at first or given in dextrinated form, as zweibach or toast. The following plan may be adopted in most cases with success: For a man weighing 160 pounds, during the first week or ten days one-third pound of rare steak, well cooked, veal, mutton, lamb, chicken, or turkey; sixty grams of toast or zweibach, a glass of milk and cream, equal parts; an ounce of butter, and, if desired, a soft egg or a hard-boiled egg grated for each of the three meals a day. If constipation is present, stewed apples, prunes or figs may be added to the diet. As a rule, little discomfort aside from a slight fullness is experienced. A powder of calcined magnesia and sodium bicarbonate, equal parts, ʒss, may be given after meals, at the time discomfort appears. A gain of two and three pounds will usually be recorded during the first week. The diet is then enlarged. Rice, oatmeal, well-cooked vegetable purée, stale bread may gradually be substituted for toast, and after four or five weeks a normal diet may be resumed. The patient should be instructed to avoid certain-named articles, and at the first intimation of an attack the restricted diet should be resumed for a few days.

#### Dietetics in Diabetes.

Dr. A. C. Croftan's paper on this subject will appear in The Journal.

#### Dietetics in Bright's Disease.

Dr. Arthur R. Elliott confined his discussion to a consideration of the most important recent advances in this field of research. Among substances excreted with difficulty in nephritis are urea, inorganic sulphates, creatinin, urine pigments, hippuric acid, phosphates and, under certain circumstances, water. He therefore excludes, on account of urea and inorganic sulphates which they contain, all proteid foods over and above the amount necessary for purposes of systemic nutrition; on account of creatinin, meat extracts and broths; on account of urine pigments, foods containing hemoglobin. On account of phosphates, he advises that calcium carbonate be given in medicinal doses several times daily, when the patient is taking milk freely, in order to arrest the phosphoric acid in the bowel, when it remains in combination with calcium. On account of the hippuric acid which they contain, he excludes certain green vegetables, cranberries and fruits containing kernals (prunes, plums, etc.).

On account of uric acid and alloxin bodies, he excludes all glandular organs used as foods, i. e., kidneys, liver, sweetbreads; also coffee and all malt beverages. Alcohol is also forbidden, save for medicinal purposes.

Milk still remains the staple article of diet in acute nephritis. The more nearly the disease approximates the acute form, the more exclusively should milk be used as the chief source of proteids. Exception is taken to exclusive milk diet in acute nephritis, owing to the poverty in iron, and the large quantity (three to four liters) necessary to furnish the nutritive calories needful for systemic purposes. It is advised, therefore, to enlarge the milk regimen by the addition of simple farinaceous foods and modify the milk by the addition of sterile cream in the proportion of one to four of milk. Of this mixture, one and one-half to one and three-quarters liters a day is allowed the patients with acute nephritis. As convalescence progresses, the diet is gradually extended. Full normal diet should not be permitted until all signs of nephritis have disappeared in the urine. Exclusive milk diet is inapplicable to the treatment of chronic nephritis, owing to the nutritive deficiencies and unfavorable influence on pulse tension. During the stage of dropsy in acute nephritis water is one of the substances excreted with difficulty by the kidneys. As the case improves, the fluids may be increased.

In chronic interstitial nephritis the vegetarianism of some clinicians is to be condemned, on account of its bulk, nutritive deficiencies, and high content of water. Meats are a necessary part of the diet in this disease, and it is a matter of indifference whether white or red meat is taken. We must, nevertheless, strictly confine the amount of proteid food within certain fixed limits, corresponding to 100 grams of albumin. It should never be forgotten that every patient with interstitial nephritis also has heart disease, and that high tension and cardiac failure are constantly menacing elements. Consequently the simple rules of cardiac hygiene, of which moderate sized meals and limitation of fluids are among the most important, must be enforced.

## Therapeutics.

**[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]**

### Herpes Zoster.

Brodier, according to an abstract in *N. Y. and Phila. Med. Jour.*, recommends the following general and local treatment of herpes zoster: The eruption should be protected from friction by means of ointments, powders or alcohol dressings. The affected areas may be painted with picric acid or silver nitrate solutions. As an ointment to relieve the pain and to act as a protective, one of the following combinations is recommended:

| | | | |
|---|---|---|---|
| ℞. | Acidi borici | gr. xv | 1 |
| | Pulv. amyli | | |
| | Zinci oxidi, āā | ʒss | 2 |
| | Liq. petrolati | ℥ss | 15 |

M. Ft. unguentum. Sig.: Apply locally; or:

| | | | |
|---|---|---|---|
| ℞. | Cocainæ hydrochlor. | gr. iii | 20 |
| | Liq. petrolati | ʒvi | 24 |

M. Ft. unguentum. Sig.: Apply locally.

After opening the phlyctenules, a simple aseptic powder may be dusted on thickly and a bandage dressing applied, renewing it daily without washing the lesion. If the vesicles become infected the following antiseptic powder will be of value.

| | | | |
|---|---|---|---|
| ℞. | Acidi borici | | |
| | Iodoformi, āā | gr. lxxv | 5 |
| | Pulv. amyli | ℥i | 30 |
| | Zinci oxidi | ʒiii | 12 |

M. Sig.: Apply locally. If the pain proves to be troublesome one-third of a grain of the cocain may be added to one of the foregoing. In aged individuals, according to the author, the pain caused by herpes is sometimes agonizing. Under such circumstances the following pill is advised internally:

| | | | |
|---|---|---|---|
| ℞. | Ext. hyoscyami | | |
| | Ext. stramonii | | |
| | Ext. belladonnæ, āā | gr. 1/10 | 006 |

M. Ft. pilula No. i. Sig.: One such pill four times a day. The insomnia, if present, may be relieved by moderate doses of chloral hydrate or the bromids. Gelsemium, aconite or acetanilid may be given internally to relieve the severe neuralgia which frequently follows herpes.

### Radium in Treatment of Cancer.

According to W. J. Morton, in the *International Jour. of Surgery*, radium can be applied in a practical manner in the treatment of carcinoma of the throat or uterus. Radium gives forth emanations similar to those of a Crookes tube, and may be held in small glass tubes, which can be easily introduced into those cavities where it has been impossible to introduce the Crookes or the *x*-rays.

### Mercury Hypodermically in Syphilis.

The following combination of mercury with chloretone is recommended by S. P. Collings, in *Interstate Med. Jour.*, in the treatment of syphilis:

| | | | |
|---|---|---|---|
| ℞. | Hydrarg. bichloridi | gr. viiss | 50 |
| | Sodii chloridi | gr. iv | 25 |
| | Aquæ | ʒi | 4 |

M. Ft. solutio (gently heating); et adde:

| | | | |
|---|---|---|---|
| | Chloretone | gr. viiss | 50 |
| | Aquæ destil. | ʒv | 20 |
| | Alcoholis (absolute) | gtt. xv | 1 |

M. Dissolve the chloretone in the five drams (20.00) of water, add the alcohol and finally the solution of mercury. Sig.: Shake well, filter and inject ten drops every four or five days, increasing the dose as indicated.

### Calcium Chlorid as a Hemostatic.

Bartignon, in *Courier of Med.*, recommends the use of calcium chlorid as a hemostatic in hemorrhages from whatever source, and especially in hemophilia. In his experience it surpasses in efficiency, perchlorid of iron, antipyrin, ergotin, and does not disturb the stomach as do some of the preparations just mentioned. He employs it combined as follows:

| | | | |
|---|---|---|---|
| ℞. | Calcii chloridi | ʒi | 4 |
| | Syr. opii | ℥iii | 90 |
| | Aquæ | ℥iv | 120 |

M. Sig.: The entire amount to be taken in twenty-four hours, in divided doses.

### Expectorants and Inhalations for Cough in Children.

In the treatment of coughs in children, Augustus Caillé, in the *Post Grad.*, recommends expectorants to aid Nature in expelling the secretions, particularly in feeble children and very old people. Ipecac, ammonia, benzoic acid, camphor and potassium iodid are given as good examples. However, when the cough has its origin in the nasopharynx salt water or albolene spray is indicated or local cauterization with a 2 per cent. solution of silver nitrate. When the origin of the cough is located lower down in the respiratory tract the author employs the following combinations:

| | | | |
|---|---|---|---|
| ℞. | Tinct. opii camph. | ʒii | 8 |

Sig.: Five to fifteen drops in sugar water once or twice at night to check the cough in a child.

The foregoing is recommended for use only in urgent cases.

The following may be substituted:

| | | | |
|---|---|---|---|
| ℞. | Tinct. opii camph. | | |
| | Vini ipecacuanhæ, āā | ʒii | 8 |

M. Sig.: Five to fifteen drops at one dose, to be repeated once during the night if necessary as a sedative and expectorant for a child; or:

| | | | |
|---|---|---|---|
| R. | Liq. ammon. anisati | ʒii | 8 |

Sig.: One-half a drop to five drops in sugar water several times a day for children as an expectorant; or:

| | | | |
|---|---|---|---|
| ℞. | Ammon. chloridi | ʒss | 2 |
| | Tinct. opii camph. | ʒi | 4 |
| | Syr. pruni virg. | | |
| | Aquæ, āā | ℥i | 30 |

M. Sig.: One teaspoonful every three hours for adults, to check cough; or:

| | | | |
|---|---|---|---|
| ℞. | Potassii iodidi | | |
| | Tinct. opii camph., āā | ʒi | 4 |
| | Liq. ammon. anisati | ʒss | 2 |
| | Syr. tolutani | ʒvi | 24 |
| | Aquæ q. s. ad | ℥iv | 120 |

M. Sig.: One-half to one teaspoonful three or four times a day, as an expectorant for children and adults; or:

| | | | |
|---|---|---|---|
| ℞. | Camphoræ (tritæ) | gr. ss | 03 |
| | Acidi benzoici | gr. ii | 12 |

M. Sig.: To be taken in sweetmeats three times a days as an expectorant for children.

He recommends, also, terebene and terebene hydrate in any form of chronic bronchitis as an expectorant, the dose ranging from two (.12) to five (.30) drops in syrup or sugar or given in the form of an inhalation. As to inhalations, the various saline antiseptic and balsamic inhalants, as vapors and sprays, are of little value as compared with the soothing effects of breathing pure mountain or seashore air. It is of value, in private practice, to moisten the air of the sick room by evaporating water from an open vessel or croup kettle over a flame to which one of the following preparations has been added: Terebenthina, oil of eucalyptus, compound tincture of benzoin, terebene, or creosote. According to the author the value of oxygen inhalations is overrated.

The foregoing stimulants and expectorants are of value in overcoming dyspnea of cardiac or pulmonary origin.

In the treatment of the cough in acute bronchitis, Comby, in *Twentieth Cent. Pract. of Med.*, states that opium preparations should never be given for fear of paralyzing the lungs and lessening the reflex cough by means of which the bronchial tubes are kept open. He does advise emetics, purgatives, such as ipecac, calomel, and scammony.

Revulsion should also be carried out by means of cups, mustard plasters or tincture of iodin. Sprays are of value and the room should be saturated with antiseptic vapors. Brandy or rum should be given if there is much depression. The limbs should be well protected, if necessary, with cotton, and the child isolated. In chronic bronchitis, in addition to the local treatment, the author recommends cod liver oil, iodids and sulphur preparations internally.

### Variola (Smallpox).

The following combinations are of value, according to *Jour. des Pract.*, in the treatment of smallpox:

| | | | |
|---|---|---|---|
| ℞. | Hydrarg. chloridi corros. | gr. 3/4 | 05 |
| | Lanolini | | |
| | Liq. petrolati, āā | ʒii | 8 |

M. Ft. unguentum. Sig.: Apply locally.

As an antiseptic spray for the eruption the following combination is recommended:

| | | | |
|---|---|---|---|
| ℞. | Hydrarg. choloridi corros. | | |
| | Acidi tartarici, āā | gr. xv | 1 |
| | Alcoholis | gtt. lxxv | 5 |
| | Spts. etheris sulphurici q. s. ad | Oi | 500 |

M. As a spray locally to the affected areas two or three times a day, protecting the eyes with gauze while using the spray.

As an eliminant, the following combination is recommended as of use in the early stages of smallpox:

| | | | |
|---|---|---|---|
| ℞. | Ammon. acetatis | ℥ss | 15 |
| | Aq. menthæ pip. | ℥iii | 90 |
| | Aquæ destil. | ℥ii | 60 |

M. Sig.: One tablespoonful every hour.

In the hemorrhagic cases the following combination is of value:

| | | | |
|---|---|---|---|
| ℞. | Calcii chloridi | ʒiss | 6 |
| | Solutionis gum arabic (30 per cent.) | ʒx | 40 |
| | Tinct. cinnamomi | ʒiiss | 10 |
| | Syrupi acaciæ q. s. ad | ℥v | 150 |

M. Sig.: The entire amount to be taken in twenty-four hours in divided doses, a tablespoonful being taken at each dose.

### Lotion for Cracked Nipples.

The following combination has been recommended in the treatment of cracks or fissures in the nipples:

| | | | |
|---|---|---|---|
| ℞. | Acidi carbol. | gtt. xv | 1 |
| | Aq. laurocerasi | | |
| | Glycerini, āā | ʒi | 4 |
| | Sol. acidi borici (saturated) | Oi | 500 |

M. Sig.: Apply freely to the affected areas.

### Some of the Uses of Carbolic Acid.

Pure carbolic acid, according to W. J. Krausi, in *Merck's Archives*, can be applied to any part of the body or the openings of the body if it is immediately followed by its antidote, alcohol. It may be used on varicose or indolent ulcers with excellent results if followed up immediately by alcohol. The hypodermic injection of a 3 per cent. solution of carbolic acid in and around the bases of furuncles, carbuncles or malignant pustules, gives very satisfactory results, relieving the constitutional symptoms and hastening repair. In pruritus, carbolic acid applied locally followed by alcohol gives instantaneous relief. In lymphangitis, the same treatment along the line of lymphatic inflammation is of great benefit. Erysipelas can be prevented from spreading by the application of pure carbolic acid, and when the skin begins to turn white the alcohol should be applied, followed by the application of gauze steeped in a 1 per cent. carbolic acid solution. In this way, according to the author, the temperature may be reduced to normal and no internal medication may be necessary.

The following combination is serviceable in relieving the itching *in the dry form of eczema:*

| | | | |
|---|---|---|---|
| ℞. | *Acidi carbol. (pure)* | ʒii | 8 |
| | *Glycerini* | ʒiv | 15 |
| | *Aquæ* | Oi | 500 |

M. Ft. lotio. Sig.: Apply locally for the relief of the itching.

In specific ulcers repeated application of the following will produce healthy granulations at the base of the ulcer:

| | | | |
|---|---|---|---|
| ℞. | Acidi carbol. | gr. xv | 1 |
| | Alcoholis | ʒiv | 15 |
| | Glycerini | ʒi | 4 |
| | Aquæ q. s. ad | ℥iv | 120 |

M. Sig.: To be applied locally.

In urticaria the following combination is recommended:

| | | | |
|---|---|---|---|
| ℞. | Acidi carbol. | ʒi | 4 |
| | Acidi borici | ʒiv | 15 |
| | Alcoholis | ℥ii | 60 |
| | Aquæ | Oi | 500 |

M. Ft. lotio. Sig.: Apply locally.

In tinea tonsurans, tinea favosa, and tinea versicolor a solution containing equal parts of carbolic acid (5 per cent. solution) and glycerin is of value.

## Medicolegal.

**Evidence of Right to Practice—Suing Married Woman.**—The Supreme Court of Georgia holds, in the case of Trentham vs. Waldrop, that where a physician brings an action against a patient to recover for professional services, and alleges that he is a duly licensed, practicing physician, and this allegation is denied by the party sued, a certificate of the clerk of the superior court of the county of his residence, showing that such physician duly registered prior to the year 1895, in compliance with the provisions of Section 1479 of the civil code, is prima facie evidence of his right to practice medicine. Where, in such an action, it appears that the party sued was a married woman, having a separate estate, and the physician testifies that she, before the services were rendered, agreed to be herself responsible for payment for them, while the party sued pleads and testifies that she made no such special contract or promise, there is such a conflict in the evidence as should be submitted to the jury, and it is error to direct the jury to find in favor of the party sued on this issue.

**Physicians Appointed by Court as Witnesses.**—The Supreme Court of Washington holds, in the personal injury case of Smith vs. City of Seattle, that an instruction was properly refused which was requested to the effect that two physicians who had been appointed by the trial court as a commission to make a physical examination of the party injured were witnesses neither in behalf of the one side nor the other, and this fact the jury might take into consideration in determining their credibility, interest in the result of the case, and the weight to be attached to their testimony. The Supreme Court says that while it was true that the physicians in question had been appointed by the court to make the examination, yet they testified as witnesses called by the city. To have given the instruction would have been for the court to say, inferentially at least, that the jury were at liberty to give greater credence to the testimony of these witnesses because they had been selected by the court. This would have been clearly erroneous. Their testimony must be subjected to the same tests as that of other witnesses, and it would have been error for the court to distinguish it as being subject to any different rule.

**Sufficiency of Reporting Births by Mail.**—The case of the Department of Health of the City of New York vs. Owen was brought to recover from a physician $100 penalty for an alleged failure to report facts relating to the birth of a child, as required by the city charter. The physician testified that he made a written copy of his register of the birth, and mailed it, inclosed in a properly addressed, postage-paid envelope, to the department within ten days after birth. The only testimony on behalf of the department to indicate that this report was not received was given by the assistant register of record, who testified, in substance, that he had personal charge and control of the records of births; that they were received by him personally; that he made a search of the records of the department for a certificate of the birth in question; that there was no such certificate there; and that the usual custom prevailing in the department as to notification by a physician of a birth was that such notice, as a general rule, was mailed and sent through the postoffice. From this evidence, the Appellate Term of the Supreme Court of New York says, the conclusion followed that the physician's report, having been duly mailed, was received by the department, as its testimony on this point did not go so far as to amount to a denial that it was received. The fact that it may not have been among the records of the department at the time search for it was made was not evidence that it was not received there by mail in due course. It may have been received, and afterward lost or mislaid. But it was contended that even if this report was mailed by the physician, still the statute was violated; it being claimed that the report should have been taken personally to the office of the health department and left there. The court holds that this construction of the statute could not be sustained. It says that the statute does not require the physician to report a copy of his register as "notice" to the health department, in order for it to protect itself against an invasion of any of its rights. The report is required in order that a public record may be made from it, and there appears to be no good reason why the information required by the statute can not be imparted to the health department as certainly by mail as by requiring physicians to attend personally at the department for the purpose of handing in these reports. There seems to be no public necessity calling for the construction of the statute in the manner urged by the department. If it were so construed, there would, in all probability, be more failures of physicians to make their reports in person at the department than there are now when they may adopt the more convenient method of mailing those reports. Furthermore, the court says that the statute which was the basis of this action was penal in its nature, and its terms should not be enlarged by judicial construction, while the legislative intent as expressed in the statute could be effectively accomplished without the interference of the court.

**Liability for Services Rendered Smallpox Patient.**—The Supreme Court of Georgia says that, taking the evidence in the case of Smith vs. Hobbs, an action for professional services, most strongly against the party suing and most favorably for the one sued, it appeared that the party sued and other members of his family were afflicted with smallpox in the city of Gainesville; that the city authorities caused his house to be quarantined, and sent the party suing as a physician to treat him and other members of his family, all this being done without consulting the party sued; that the latter at no time employed the physician, or agreed to pay for the services rendered to him, but simply received the services as rendered, acting on the assumption that, as the city authorities had taken control of his premises, and had sent a physician whom he had not employed, and who was not his family physician, they intended to provide for all of the expenses incident to the treatment of the disease with which he and other members of his family were afflicted. There was evidence for the party sued authorizing the jury to find that at the time the services were rendered the conduct and sayings of the physician were such as to indicate to him that the physician did not intend to hold him liable for the services so rendered. This was the case taken most favorably for the party sued. Of course, there was evidence to the contrary, and which, the court says, would have authorized a finding for the physician. But the jury rendered a verdict in favor of the party sued; and the court holds that the evidence authorized it. In Sections 1472-1474 of the political code it is provided that, when smallpox has appeared in any city, the city authorities are empowered to provide a suitable hospital for those afflicted with the disease, and to furnish them with medical and other attention; and also authorizing the city authorities to provide quarantine regulations to prevent the spread of the disease, but not to require any person to leave his home and go to the hospital when he is properly provided for and quarantined elsewhere at his own expense; the act providing that the city shall not pay the expenses of any person so situated. The court holds that the provision that the city shall not pay the expenses of a person quarantined and provided for at his own home is applicable only in cases where a suitable hospital has been provided, and the person afflicted has been given an opportunity to be carried there, and has insisted on being treated at home. The party sued had a right to show that he was not liable, and evidence that another was liable for the account sued on was a proper matter to be considered by the jury in determining the liability of the party sued. It was not necessary that there should be any special plea setting up that the city was liable to authorize evidence of its liability for the purpose of showing non-liability on the part of the party sued. The city was not a party, and the judgment in this case would not bar a suit against it to recover the amount of the claim, though the question of whether the city was liable, the court says, was not involved in this case and was not passed on.

4 Hallucinations of Vision. Howard F. Hansell.
5 *An Unusual Form of Tuberculous Disease of the Chest. J. N. Hall.
6 *Operation for the Radical Cure of Inguinal Hernia in Young Children. Pearce Kintzing.

1.—See also §85 below.

2. **Congenital Intra-uterine Poliomyelitis and Neuritis.**—The case reported by Fränkel and Onuf is given in detail and includes the study of several thousand careful sections. The child was four years old, had luxation of the right radius and of the left hip, motor disturbances of all four extremities, bilateral wrist-drop, drop-foot, disturbances of speech and of facial innervation. Cranial innervation was asymmetrical, the face being drawn to the left side. Other than the seventh, the cranial nerves were normal. The patient died from malignant diphtheria. After autopsy a careful microscopic examination was made, which had been so delayed that histologic interpretation was to some extent embarrassed. The causes of the condition are discussed at length. The authors rather favor the probability of congenital, intra-uterine poliomyelitis and neuritis with a suggestion of lead poisoning as a cause.

5. **Tuberculosis.**—Hall reports two personal observations and refers to one reported by a brother physician in which there were temporary manifestations of tuberculosis, hemorrhage, tuberculous sputa, loss of flesh with bronchial and laryngeal symptoms, but an absolute lack of physical signs or permanent disability. He does not believe that the pus and bacteria came from the lung proper, nor does he accept the suggestion of a small cavity, from which they might have occasionally

escaped. He thinks we can best account for the conditions by assuming a slow, chronic tuberculous ulcerative process in the bronchial glands.

6. **Inguinal Hernia in Children.**—Kintzing speaks of the hopelessness of expectant and mechanical treatment in many of these cases and describes the operation which he has performed. The youngest patient was one and a half years old. In this case the sac of the hernia and the tunica vaginalis testis were continuous, and the various elements which go to form the cord were spread out on the sac, as though forming an integral part of it. It was necessary, therefore, to first free the sac up to and well within the internal abdominal ring, then to slit it up within a short distance of this point, to free and return its contents to the abdominal cavity. After separating the vas deferens and its vessels and ligating the supernumerary veins, the sac was ligated at as high a point as possible, and one thread left long for transplantation of the stump. This transplantation is best done by passing a long-curved needle downward and inward through the transversalis fascia toward the conjoined tendon, and drawing the stump behind and against this structure. His plan has been to draw up the downward continuation of the sac, until the upper orifice of the scrotum is reached; then to cut off at this point the cuff-shaped expansion which has formed the hernial sac, leaving a tongue-shaped process to which is attached the cord as above described. In his experience, the remaining portion which drops back into the scrotum, even though much thickened, has taken care of itself without producing trouble. The omentum contained in the sac was, of course, freed and returned or removed as deemed necessary. The suturing was done in the usual manner, and the dressing retained by a plaster-of-paris spica around the thigh and the crests of the ilia, kept on about four weeks. This style of dressing prevents movement of the parts, and yet the child can be kept out in the fresh air.

10 *Some Subjective Hints of the Morphin Habit. William Lee Howard.
11 *Hemorrhagic Diseases and Their Allies in the Light of Modern Pathology. F. L. Wachenheim.

7. **The Social Evils of University Life.**—Wilson points out the dangers from gonorrhea and syphilis, especially to students, and the impolicy—to say nothing of the wickedness—of being other than pure in life.

9. **Incontinence of Urine.**—Cumston's article describes the various forms of acquired incontinence in women and the operations for its relief.

10. **The Morphin Habit.**—Howard gives certain diagnostic hints as regards the morphin habit, and calls attention to the necessity of keeping any suspicion from the patient. Watch the conditions, especially if in the afternoon, to see whether she is under the effect of the drug. If she comes complaining of a distressed feeling, ill health, irritability, etc., treat the condition, but insist that the treatment must be continued for weeks, laying considerable emphasis on the importance of seeing the patient at a certain time. Make an appointment for the next day at an early hour. The next day the appointed hour passes, and when the patient finally arrives, her excuses must be accepted. Again notice the general attitude of the patient. It may or may not vary with that noticed the day before, but the treatment must be the same. The physician must find out as to the conditions in the morning, as to the appetite, slowness of rising, etc. The patient is again late on the third day. Then he should appear at the house the next morning at a reasonable hour, with the excuse that he could not keep the office hour, and not wishing to have the day pass without seeing her, he called. It is probable that he would be told that she is not yet down and "Will he wait?" He may be detained half or three-quarters of an hour when she appears with every evidence of a hasty and careless toilet, moist skin, pale face and vapid, filmy eyes, and he is now satisfied that he is on the right track. The small amount of the drug taken will probably require her to ask to be soon excused, but after this the observer must see her under different conditions, e. g., at night when she is under the drug's control, and compare the two conditions. Make another engagement for an early hour, and if it is not kept, you will realize how impossible it is for her to recognize the value of time or promises. It is not much use to note the condition of the pupils, for the patients become expert in the use of atropin. A urinary examination may be advised, only to find that other samples have been substituted. The statements of the intimates of the patient should be sought but taken guardedly. If all accounts agree that the morale of the patient is gradually changing, she being careless of her statements, of engagements and of her sense of relationship to others, we can come to the conclusion that we are dealing with a user of morphin.

11. **Hemorrhagic Diseases.**—Wachenheim sums up his arguments as follows:

> We find that hemophilia, congenital or acquired, is a toxinemia with secondary autoimmunization to a quasi normal function; *that* the scorbutic affections are chemical autointoxications, hemorrhagic *only because* the blood is especially involved; and that the *purpura* rheumatica group is only a manifestation of ordinary rheumatism or sepsis. *After this* exposition of their very diverse nature, it seems clear that the old class of the hemorrhagic diseases has become obsolete, should be relegated to the domain of historic medicine, and cease to appear in our monographs and text-books to further puzzle the student and physician. . . . . . Winckel's disease, melena neonatorum, paroxysmal [illegible] allied clinical pictures must be regarded not [illegible] but as *symptom groups*; like the other outward [illegible] they have been placed among the hemorrhagic diseases; their proper position is under the various heads of sepsis, congenital syphilis, malaria, autointoxications, and so on, according to the individual case.

### New York Medical Journal.

*January 16.*

12 Psychic Healing, or, Properly Speaking, the Treatment of Disease or Supposed Disease by Mental Influence. Edward Wallace Lee.
13 *The Relation of Early Diagnosis and Treatment *to the* Prevention of Tuberculosis. F. M. Pottenger.
14 Simple *and Inexpensive* Apparatus for Lifting and Moving Helpless Patients. Frederick H. Sawers.
15 *Concerning the Accuracy of Percentage Modification of Milk for Infants. (Concluded.) David L. Edsall and Charles A. Fife.
16 *Some Investigations of a Bacterial Treatment of Tuberculosis. (Continued.) Stephen J. Maher.

13. **Tuberculosis.**—In order to detect tuberculosis, Pottenger says it is not necessary to wait until the bacillus appears in the sputum. If the physical signs and other diagnostic characteristics fail, the tuberculin test can be used with confidence and safety. Too much importance, however, must not be laid on physical signs, but careful attention be also given to the clinical history. While the disease is pure tuberculosis, it consists of nothing more than a few tubercles, leucocytes and proliferated-fixed cells, with very slight local irritation and slight general constitutional disturbance. Later, as the tubercles multiply, the whole disease changes. There is congestion with exudation, and a pneumonic process supervenes, cavities form and other germs enter, making a mixed infection, with all the symptoms of consumption. Tuberculosis is curable, but as regards consumption no one has been empowered with the ability to generate new cells, and without this, absolute cure can not be secured, though the condition may be arrested. Both, however, should be treated. Tuberculosis patients, he says, are apt to be indiscrete—waste their time and energy on fruitless treatments. The profession is not doing its duty in not telling them the nature and extent of their case, and they are often borne up by fallacious hopes of cure; whereas, in 80 per cent. of cases, if treated in the beginning under proper conditions, cure can be expected. Hygienic treatment is insisted on. He believes in the use of tuberculin, but it must be understood that serums have their specific action on tuberculosis and not on consumption. The advantages of sanatorium treatment are extolled as giving the best chance of recovery, and removing the patient from the danger of infecting others.

15. **Milk Infection.**—The general conclusions which Edsall and Fife consider justified are:

> 1. Milk modifications, under the best conditions, will often vary 0.2 per cent., occasionally 0.3 per cent. from the prescribed formulæ, with modifications of medium strength. With low modifica-

tions, the error will be correspondingly less; and with high modifications, correspondingly somewhat greater.

2. Home modifications are, within the limits just mentioned, trustworthy, if they are made by a clear-headed and careful person, from milks and creams of a chemical composition that is known to be reliable.

3. If the composition of the milks and creams used is not known, or if one can not be sure that the modifier is careful and clear headed, home modifications are likely to vary greatly from the formulæ prescribed.

4. Laboratory modifications appear from our figures to be satisfactorily accurate; and unless the milks and creams, as well as the person doing the modifying at home, can be fully trusted, laboratory modifications, when available, are much more reliable than home modifications.

While the most satisfactory method would be to have a thoroughly competent person make the modifications at home, it is necessary that a perfectly clear-headed mother or nurse should accomplish this. The authors are somewhat doubtful as to the accuracy in many cases, and nothing should be left to judgment or memory. There is a great advantage in using milks and creams that are under constant professional control and certified as being reliable. He advises occasional control tests of milk modifications done at home, by the physician or an assistant, as keeping them up to a proper point of accuracy.

16. **Tuberculosis.**—Maher gives a history of his method as practiced in the Seton Hospital, at Spuyten Duyvil, where he has used the cultures on some 60 cases, a number of which are reported with decidedly striking results. No compulsion was used in securing the patients and no promises of cure were made. Only the harmlessness of the method was assured. The larger number of the cases have not been under observation long enough to enable him to speak positively as to results, but an encouraging number show evidence of improvement. Some of the cases he reports are certainly rather remarkable.

19 Some Cases of Intussusception. Franklin G. Balch.
20 *The Bicycle as a Therapeutic Agent. Luther H. Gulick.
21 *Mercuric Cyanide as a Surgical Disinfectant. Charles Harrington.

17. **Cardiac Displacement.**—The possibilities of cardiac displacement in its different forms such, for example, as complete dextrocardia and mirror heart without general visceral transposition, are discussed by Stone. So far as he can find, no case of mirror heart has been put on record, though Graanboom has reported one of congenital dextrocardia with a peculiar arrangement somewhat suggestive as far as the appendages are concerned. He goes over the various forms of acquired changes, and says we must remember that in case of displacement, the heart tends to move as a mass to the right or left, and that rotation is very rare. When found, it is accompanied by exceptional conditions or is brought about by the presence of contracting adhesions; that practically in all cases the visible cardiac impulse to the right of the sternum is caused by the base of the heart and not by the apex; that extreme displacement may take place without the slightest discomfort, and that sudden death occurring in cases of large pleuritic effusions is not due to the cardiac displacements.

20. **The Bicycle.**—According to Gulick, the bicycle is a useful therapeutic agent where it is desired to increase the general organic functions of the circulation, respiration and digestive tract. Its advantages are that it exercises the large muscle masses by a great number of small efforts, that it is automatic and calls for no great neural expenditure, is taken in the open air, and, in proportion to the work done, there is little consciousness of fatigue. It is available anywhere, and with it there may be the advantages of varied scenery and good companionship.

21. **Mercuric Cyanid.**—Harrington has experimented with silk threads impregnated with 24-hour-old cultures of pus microbes, then subjected to the influence of a 1/1000 solution of pure mercuric cyanid. After varying periods of contact they were withdrawn and planted in sterile bouillon and incubated for twenty-four hours. The results were striking, and the conclusion he reaches is that the practical value of mercuric cyanid in the strength recommended is nil, and that it can not destroy all known species of pus organisms within three hours, and in double that strength accomplishes nothing within thirty minutes. It can, therefore, hardly be classed among the effective germicides.

22 *The Serum Treatment of Typhoid Fever. Max Einhorn.
23 *The Roentgen or Tri-ultra-violet Rays, Their Nature, Application and Dermatologic Effects. Francis Le Roy Satterlee, Jr.
24 *X-ray Dermatitis as Influenced by Idiosyncrasy. A. D. Rockwell.
25 *Liquefied Air. A. Campbell White.

22. **Typhoid Fever.**—Einhorn first notices the history of the serum treatment of typhoid, reviewing the statements of Jez, Widal and others, and gives his own experience. He employed the antityphoid fever serum of Jez and Tavel of the Berne Board of Health. He chose to use the injection method rather than to give it by the mouth, though in a few cases he also tried it in that way. As soon as the diagnosis of typhoid was made, usually with the positive Widal reaction, 6 to 12 c.c. of serum were injected daily until the temperature remained under 100 F. The cases chosen were all medium, grave and severe hospital cases. The total number of patients was 10. The details and temperature curves are given. He finds from his study that in most cases the disease did not appear to be materially shortened, but a marked reduction of the fever usually occurs, either the day after the first or after the second injection. The remission is one or two degrees lower, and the general condition, especially the sensory and nervous symptoms, were most improved. Some grave complications, like sleeplessness, headache, restlessness, delirium, etc., disappeared almost entirely. The treatment was usually begun from the ninth to the fifteenth day. He thinks still better results would be obtained with earlier recourse to the serum. While the series is small, he thinks the cases indicate that the serum treatment temporarily reduces the fever and improves the general condition so that the patients go on to more rapid recovery and safer convalescence. He has not observed any dangers connected with the injections. There was never any serious trouble. In two cases only a passing erythema of the skin was observed at the point of injection. In one case chills used to follow after quarter to half an hour. Abscesses were never observed. He favors the treatment and believes that we will yet have still better effects from a more potent serum.

23. **The Roentgen Rays.**—Satterlee gives the history of and the theories that have been offered in regard to the Roentgen rays, the character of the tubes, etc., and notices their value as a diagnostic and curative agent. He criticises the opinion that the Roentgen ray is a positive diagnostic agent as distortions have occurred, but this does not detract from its general value as an important factor in the diagnosis, especially in locating conditions. The rays have been used in some of the most formidable diseases that affect mankind, such as lupus, carcinoma, enlarged glands, phthisis, rodent ulcer, etc., and while time has not yet sufficiently elapsed to show the absolute permanency of some of the cures, yet enough has been discovered to show their value. In many cases it may be necessary to produce dermatitis, while in others a few treatments will bring about effective results. He thinks the promises for the future are still better than have been the results of the past and present.

24. **X-Ray Dermatitis.**—Rockwell calls attention to idiosyncrasy as affecting the probability of *x*-ray dermatitis, and reports cases showing susceptibility. He thinks we should never fail to interrogate as to idiosyncrasy, such as to sunburn, ivy poisoning, from eternal applications, before using the *x*-rays. In one case in his experience, where no appreciable dermatitis was produced, the slightest exposure caused the most unpleasant sensations of burning and itching, and the patient was likewise specially subject to ivy poisoning. Advanced malignant cases are another matter—the burn may be of small value relatively; but in simple, uncomplicated skin affections the production of a dermatitis of the second or third degree may be regarded as worse than the disease.

25. **Liquefied Air.**—White describes liquefied air and its properties, calling attention to its value as a local anesthetic

and for treatment in inflammatory conditions. He thinks in inflammatory processes, where application of cold is desirable, the condition can be better and more pleasantly managed with liquefied air applications than in any other way, using exposure to the vapor from liquid air, or soaking a towel in the liquid, and quickly and intermittently applying it to the part, or rolling a glass bulb containing the liquid over the part, etc. To produce an inflammation or stimulating effect, the liquid air must be applied directly and intermittently to the skin. In chronic indolent ulcerating surfaces, by spraying just sufficient to freeze for a second only, a good healthy granulating surface will be obtained, and foreign growths can be destroyed in the same way. The air inflammation subsides quickly and responds readily to hot boracic acid or carbolic fomentations. A nevus or birthmark, if judiciously treated, can be removed by this more quickly and with less pain than by any other method. The greatest danger to be avoided is excessive freezing, which may produce inflammations as severe as those destroyed. Hemorrhage is not likely to occur even in very vascular nevi or hemorrhoids. In the treatment of carbuncle, not too far advanced, liquid air seems to act as a specific. In all cases of carbuncle less than 3 inches in circumference it was aborted in one hour after a thorough freezing. In larger ones he sprayed the cavity after a crucial incision, with prompt healing. He recapitulates as follows:

> In liquid air we have the nearest approach to absolute zero ever obtained, excepting liquid hydrogen, which is many degrees colder and is liquefied by the assistance of liquid air. If there is any therapeutic value in cold we certainly have it in liquefied air, 312 degrees below zero, and from this we can obtain any desired temperature above that point. If there is any therapeutic advantage in having a dry cold, we have it in liquid air, for in anything colder than 32 degrees below zero no moisture can exist. That moist cold is more destructive to the tissues than dry cold is an accepted fact. If it is desired to produce a local anesthesia by cold, we have no means of obtaining the result equal to liquid air, for it is dry, rapid, thorough, clean, and under perfect control. That circulatory changes can be produced by the extremes of temperature, that of liquid air and the human body, is self evident, and experiments in this direction have demonstrated its therapeutic value both in the production and reduction of inflammation, according to the method of its use. Being nothing but the air we live in, reduced to a low degree of temperature, and free from the usual pollutions of the atmosphere, it surpasses all other applications previously in use for the removal of all growths of benign or malignant character, because its application is practically painless, its action more rapid than electrical methods, and there is no systemic effect whatever following its local use.
>
> If there is any value in the therapeutic use of oxygen, we have it in its most concentrated form in liquid air, from which it has been demonstrated we obtain liquid oxygen, and oxygen of much higher percentage and purer quality than obtained in any other way.

He says if the medical profession really understood liquid air and its physical properties, its therapeutic value would at once appeal to them.

26 *Gonorrhea in Women. Palmer Findley.
27 *A Few Considerations on the Etiology and Pathology of Cutaneous Cancer. (Concluded.) A. Ravogli.

**26. Gonorrhea in Women.**—Findley reviews the facts in regard to gonorrhea, its latency in certain instances, and describes the condition as it occurs in the female. He believes in the use of simple cleanliness in the acute stages, later using antiseptic solutionss to the urethra, such as 10 per cent. protargol solutions daily, curetting the uterus and applying pure formalin on a swab. If pus accumulates in the appendages it should be removed, though much may be done to facilitate absorption by conservative methods. The abdomen should never be opened during the acute stage. If the pain and toxic absorption demand interference, the abscess must be drained through the vagina or not at all.

**27. Cutaneous Cancer.**—Ravogli concludes thus:

> 1. Carcinoma is an inoculable disease. 2. Precancerous keratosis, superficial and deep cancers are identical. 3. Carcinoma in its origin is the result of a parasite. 4. The poisonous properties of this parasite are revealed on the cells, at first in a limited area, later on in the general system.

31 A Morphological Study of the Blood of Certain Fishes and Birds, with Special Reference to the Leucocytes of Birds. Ernest K. Cullen.

**30. Ascending Renal Infection.**—Sampson has studied the subject of ureteral infection and finds that the normal anatomic structure and the physiologic action of the ureters indicate that their function is not only to carry urine to the bladder, but also to prevent fluid from passing backward, and that under normal conditions it is impossible for the latter to take place, but cases have been reported where an apparent reflux has occurred. The infecting organism may be conveyed, he says, from the bladder to the kidney through the general circulation or the vesico-utero-ovario-renal anastomosis, through the ureteral blood vessels, the lymphatics or through the lumen of the ureter by injuries to the intravesical portion, by extension of an inflammatory process from the bladder along the ureteral walls, which is probably the most frequent, by organisms traveling up the ureter, especially when the current is interfered with by a stricture or something occluding the lumen of the ureter, by a reflux of urine from the bladder into the ureters, by intravesical pressure, reverse peristalsis, or by suction of air when the patients are examined in the knee-breast posture through an open cystoscope. This reflux may be considered as an etiologic factor in the causation and maintenance of renal infection only when the intravesical portion of the ureter is diseased, thus impairing its function, or when some ureteral abnormality exists. Two accessory etiologic factors of great importance must be considered: 1. An injured kidney with lowered local resistance, most frequently due to ureteral stricture from cystitis or calculi. 2. General ill health of the patient, that is, lowered general resistance. Both of these may so influence the function and resistance of the organism that it is no longer able to destroy or excrete that which under healthy conditions would have been done away with. He asks why autogenous renal infection does not occur more frequently, and why organisms are not found more often in the urine and in the blood of healthy individuals.

33 A Memoir of Desault. Charles G. Cumston.
34 Unusual Sources of Poisoning. William Davis.
35 Congenital Dislocations of the Hip. A. C. Baker.

**32. Exophthalmic Goiter.**—Schwyzer reports five cases operated on with good results. He thinks surgery offers the only good and reasonable hope in serious cases; that even in the milder cases, medical treatment can not promise anything definite. He asks why, then, even in moderate cases, if the treatment is unsatisfactory, should we not prefer an operation which in competent hands is only slightly dangerous and which, beside being a better guarantee for a more lasting cure, saves so much time and anxiety. He thinks the transitory or atypical forms or cases lacking a cardinal symptom ought not to be included as surgical cases, and only cases with distinct exophthalmic goiter should be considered. Otherwise the surgeon would run the risk of being charged with having operated on cases of simple thyroidism so often found in adolescent patients. But only in mild cases where internal treatment is satisfactory or operation is refused is internal medicine to be depended on. In all others surgical measures are advisable and preferable.

36.—See summary in The Journal A. M. A., Nov. 21, 1903, p. 1266.

37. **Pyroplasmosis Hominis.**—Wilson and Chowning give a full review of the spotted fever of Montana and its probable etiology. They see a direct relation between its occurrence and the active season of the *Spermophilus columbianus*, which probably harbors the ticks that give rise to the disease. The arguments are given in detail.

39. **Paratyphoid Fever.**—Wells and Scott give the histories and a study of five cases which indicate to them that paratyphoid infections are accompanied with quite different changes from those from typhoid. On the other hand, there is little characterizing this infection from other septicemias anatomically, however much it may differ clinically. The most constant change was the splenic enlargement which was present in all five. It seems to be the same as that of typhoid or ordinary septicemia. The microscopic findings are similar, and the anatomic changes are simply those of septicemia with splenic swelling and occasionally non-specific ulcerations in the intestine. The total escape of Peyer's patches seems to indicate some essential difference between the typhoid and paratyphoid organisms.

53 *A Tentative Suggestion Regarding the Nature and Character of X-rays. M. L. Heidingsfeld.

48. **Peculiar Inclusions in Lupus-Like Tissue.**—The case presented by Bowen was one that exhibited symptoms suggesting blastomycosis, but the lesions resembled tuberculosis more than anything. Pathologic examination showed bodies similar to those described by other observers in tuberculous tissue, but it was not possible to prove that it was a case of tuberculosis. The nature of the peculiar bodies could not be determined. There was no evidence of calcareous degeneration or that the bodies bore any relationship to elastic tissue. It was difficult to avoid the suspicion that they were parasites.

53. **The Character of the X-Rays.**—The theory of the *x*-ray here advanced by Heidingsfeld is that it consists of minute particles of platinum in a very high state of "radiant" excitation, emanating from the enclosed disc, and moving with sufficient velocity to readily penetrate the circumscribed glass enclosure and all opposed soft and fairly hard substances. This, he thinks, will explain all the physical and physiologic phenomenon. To confirm it, the detection of platinum *at the* point of ultimate deposition *must be* insured, and this is left for future study. A careful estimation of any loss of platinum from the disc after careful consumption of the tube, preferably with repeated exhaustions, would be also confirmatory, but less absolute proof.

57 *The Causation and Treatment of Eclampsia. A. Lapthorn Smith.
58 Artificial Dilatation of the Cervix Uteri with Report of a New Instrument. Frank A. Higgins.

54. **Hymen Intactus.**—Cumston calls attention to the medicolegal bearings of the subject: the necessity in all cases of noticing the normal physical conditions of the hymen, as well as the question of its actual integrity or otherwise. The possibility of coitus without rupture of the hymen should be remembered and its shape, the resistance, etc., should be considered.

57. **Eclampsia.**—Smith holds that eclampsia is due to anemia of the corpora striata or to such other brain centers as *control muscular movements*. This anemia is caused by a spasm of the arterioles, but every capillary in the body is probably likewise affected, those of the kidneys included, and the spasm-producing toxin—not necessarily urea—rapidly increases in a vicious circle. The arterioles of the brain tighten up, causing disorders of vision and headache. The circulation of the blood through the kidneys comes to a stop, as well as that in the brain, the patient loses consciousness, and convulsions begin. The treatment which he considers best is to administer one-half or three-quarters of a grain of morphin within three minutes of seeing the case, and ten drops of veratrum viride hypodermically following in five minutes and repeated every ten minutes until the convulsions stop and the pulse comes down to 40. Then he gives a quart of salt solution by enema, to be quickly absorbed as the kidney arterioles relax. The water will rush into them, and in half an hour there will be a copious secretion of poison-laden urine. No chloroform or chloral will be needed, and no forced delivery. The best way is to allow the woman to fall into a quiet slumber. This occurred in half an hour in his three cases. The physician can then go home. There will be a normal labor and probably a dead fetus in a day or week. He says you may get a fright when the pulse comes down to 40, but there is nothing to fear. He has not been able to find or hear of a case of eclampsia treated in this way, but without chloroform or chloral, that died. He thinks *chloroform administration* is enough of itself sometimes to cause the death of the patient.

59 *When Not to Prescribe Cylinders for Astigmatic Eyes, and When to Prescribe Them for Non-astigmatic Eyes. N. C. Steele.
60 *Is Double Operation for Senile Cataracts Justifiable? Howard F. Hansell.
61 *Notes *on* Some of the Newer Methods and Drugs in Ocular Therapeutics. Methylbromid of Atropin, Dionin, Subconjunctival Injections, *Jequiritol. Albert B. Hale.*
62 A Deviometer Attachment to the Skeel Perimeter. David W. Wells.

59. **Astigmatism.**—From a study of the subject, Steele *concludes that many cases* with low degrees of astigmatism with the best meridian horizontal, or nearly so, should not have the astigmatism corrected, at least not fully corrected, in lenses for near use only. This does not apply, he says, to lenses to be used for all purposes such as are generally worn by *persons under forty*, nor does it apply to simple cylinders of low degree, nor to lenses in properly selected pantoscopic frames. It applies, however, to cases where the refraction tests indicate the near use of spherocylinders with cylinder axis horizontal, because it is *chiefly* the increased converging power of the vertical meridians of spherical lenses and the spherical part of spherocylindrical lenses as used in near work that produces the condition discussed. He is guided by the following suggestions in cases of astigmatism with the best meridian horizontal in prescribing near *lenses*: If the astigmatism is of low degree with best meridian horizontal, he entirely omits the cylindric element of the lens. In high degrees of astigmatism he omits a part of the cylindric element, thus undercorrecting the absolute amount of astigmatism shown to exist by the usual tests. He depends on the spherical lenses or the spherical part of the spherocylindrical lenses to correct all or a portion of the astigmatism.

60. **Senile Cataract.**—Hansell has performed the double operation in five cases of senile cataract, and his experience inclines him to increase the number as suitable opportunities arise. He believes the double operation is justifiable when the vision of each eye is so diminished that the patient is de-

barred from his usual occupation and is consequently unable to earn a living, both cataracts being ripe enough to warrant extraction. In other words, that either lens might be operated on with equally good chances of a favorable result when nothing in the patient's physical or mental state might militate against recovery; when the cataracts are not secondary to local or general disease, and when extraction of the first lens is accomplished without accident or indications of complications should operation on the second eye be attempted. The surgical shock, he says, is hardly worth considering. The real suffering, nervousness, confinement to bed, etc., are the same whether one or both eyes are operated on.

61. **New Ophthalmic Drugs.**—Hale gives his experience with certain new drugs in ophthalmic practice. Methylbromid of atropin is first mentioned, and he has found it much quicker in disappearance than the sulphate, twelve to twenty-four hours quicker than scopolamin, and somewhat slower than homatropin. His experience convinces him that methylbromid of atropin used in a 1 per cent. aqueous solution is a trustworthy mydriatic and a good cycloplegic in refraction; an untrustworthy mydriatic in iritis, but a comfortable one in corneal inflammations; its action begins at about the same time as the sulphate, but has disappeared from two to six days before the latter; it should rank below the sulphate for complete action, but equal or above all other drugs. Dionin has not been so satisfactory in his experience. He thinks it deserves a more modest place in therapeutics than some of its advocates would give it. Its action is not lasting; it is simply an adjunct to other agents, helpful in emergency, but not trustworthy. He says, let us use it as a powder, as a 1 or 5 per cent. solution, alone or with another drug, but let us not forget that it is always the other drug on which we must rely. Subconjunctival injections and their value are also discussed. He finds that they are especially advantageous in non-suppurative diseases of the uveal tract, such as plastic choroiditis. He does not place much dependence on the method in corneal inflammation, though remarkable results have been reported. The only question, in his mind, is to decide on the best way of applying the method. The earliest theory insisted on using a solution of mercuric bichlorid for its special antiseptic and specific powers, but this has been abandoned and simple sodium solution, either 2 per cent. or higher strengths, suggested. He finds no advantage in sodium chlorid solution stronger than 2 per cent. His experience has not been favorable with hetol. Lately he has used 1 to 3,000 and 1 to 5,000 cyanid of mercury solution, to every fifteen drops of which he has added two drops of a 1 per cent. acoin solution. He has steadily used this combination, and has seen no reason to abandon it. Jequiritol has also been tested, and 6 cases of its use are reported. He does not hold that it is a complete substitute for better methods or that it will revolutionize the treatment of trachoma or vascular keratitis, but it certainly has remarkable power.

74 *The Cardiosplanchnic Phenomenon. Albert Abrams.
75 *The Etiology, Pathology and Diagnosis of Adrenal Hemorrhage. Leonard S. Dudgeon.

63. **The Visceral Manifestations of the Erythema Group.**—Osler's paper is a continuation of two former ones published by him in 1895 and 1900. In this he adds 11 new cases to those already observed, and analyzes the features of the whole group of 29 cases contained in the three papers. The conditions described were somewhat various, including different forms of erythema, certain cases of purpura, urticaria and edema. One of the most constant symptoms in the whole group, occurring in 25 of the cases, was recurring attacks of colic, showing visceral lesions. There was also acute nephritis in 14 of the cases, and hemorrhage of the mucous membrane in several. Other symptoms were less frequent, such as cardiac complications, swelling of the fauces, of the larynx in one case and brain symptoms in two. Seven deaths occurred in the series. The lesions varied in individual cases from time to time, but there was no question that all of them, with the extraordinary visceral symptoms, were manifestations of one and the same cause. Arthritis was present in 17 cases, but, as a rule, was slight. The very chronic cases, he says, may resist all therapeutic measures. Alterative courses of gray powder, with careful dieting, may be helpful. With angioneurotic edema nitroglycerin in full doses may be tried. In one case camphor did good. In such severe types as some in the series given, nothing seemed to arrest the progress. The chief danger is in the kidney complications. He mentions the importance of early precautions to prevent its progress, namely, protracted rest in bed and a milk diet, which, he thinks, are the best means at our disposal.

64. **Splenic Anemia.**—Two cases reported by Dock and Warthin indicate the clinical and anatomic peculiarities of a late and an early stage of Banti's disease; an older, splenic fibrosis and a more recent fibrosis of the liver, also stenosis and calcification of the portal vein. They ask, is the latter the primary condition, to which the splenic fibrosis is secondary, or is it the result of a portal or general intoxication, to which fibrosis of the other organs is also due? Other similar cases will be required to settle this question, but the cases reported, the authors think, favor the view that the symptom-complex of splenic anemia represents a group of varying pathologic conditions, the splenic condition being secondary.

65. **Skin Desquamation in Typhoid.**—Riesman notices the rarity of the condition and the lack of attention it has received, and says, in conclusion, that we can distinguish three varieties of desquamation in typhoid: 1. That confined to the roseolar spots; in some cases each spot has a little vesicle which passes into thin, scale-like crust. 2. That appearing as a sequel of sudamina. This is confined to the areas that have been the seat of sudaminal eruption. The desquamation is usually furfuraceous, but is sometimes scaly. It appears on the trunk and the proximal part of the limbs, but never on the distal parts of the extremities or on the face. 3. In some instances, as in the second case reported, there is an extensive, almost universal, desquamation either furfuraceous or lamellar, apparently independent of sudamina. In all probability it is a trophic change analogous to the shedding of hair. It affects the trunk and the roots of the limbs, rarely the face and distal parts. Usually the intensity of the desquamation is in relation to the severity of the fever.

66. **The Diagnosis of Typhoid.**—The following are the conclusions of Rucker's paper:

> 1. There is no single symptom on which alone an early diagnosis of typhoid fever can be made. It is only by careful consideration of the symptom-complex that a clinical diagnosis can be arrived at. 2. The most trustworthy, as well as the earliest, sign of typhoid fever is the presence in the circulating blood of the bacillus of Eberth. 3. The demonstration of the bacillus of Eberth in the blood is not beyond any fairly well equipped laboratory. 4. The bacillus of Eberth is found in the feces later than in the blood, but with comparative ease. The presence of the typhoid bacillus in the feces is of great value as a corroborative sign. 5. Its presence in the rose spots is a trustworthy sign, but has no advantages over the examination of the blood from other localities. 6. The serum reaction of Widal is seldom demonstrable during the earliest stages of typhoid fever. It is of value only in the higher dilutions.

67. **Hemianopic Hallucinations.**—Four cases are reported by Pick which seem to him to indicate the probability that such hallucinations may be induced by lesions in the optical tracts, either focal or *functional*. He points out the transition of elementary light phenomena of scotoma scintillans into real

hallucinations, which favors the idea that hemianopic hallucinations may be due to localized excitations in the optical tracts and not in the occipital lobe only.

71. **The Pseudodiphtheria Bacillus.**—Salmon describes in this article the special form of pseudodiphtheria bacillus which has been found occurring in the inmates of the Willard State Hospital. It appears in the shape of an elongated ellipse, two deeply-stained segments separated by an unstained portion, apposed base to base, usually rather equal, but sometimes one longer than the other, the short one being usually the thicker. Illustrations of both types are given, also of the appearance of such bacilli when they occur in pure cultures of the diphtheria bacillus. He thinks this type is possibly a distinct one, and its recognition as such would be a help in classifying diphtheria-like bacilli, for it is responsible for more difference of opinion in the examination of cultures from well persons than any of the pseudodiphtheria types.

74. **Cardiosplanchnic Phenomenon.**—The cardiosplanchnic phenomenon consists in the results of percussion over the lower portion of the cardiac region or the sternum in different postures. In the upright position the percussion sound will be resonant or possibly hyper-resonant. In the recumbent position it is dull and flat. Vigorous compression of the abdomen will exaggerate the phenomenon in all instances. Abrams points out the importance of this symptom as aiding in the differentiation of a dilated heart from a pericardial exudate. *In the latter it will not be elicited.* It will also be exaggerated in idiopathic syncope and vertigo, in vertiginous attacks of Glenard's disease, which may be attributed to defective splanchnic vasomotor mechanism.

75. **Adrenal Hemorrhage.**—Four cases are reported by Dudgeon, who notices the literature of the subject and its occurrence in regard to its relation with Addison's disease. He believes it is too early fatal to allow development of the symptoms of the latter. There is but one place where we are able to diagnose adrenal hemorrhage with any degree of certainty, and that is in the postmortem room.

84 Streptococcic Infection of Wounds. Ira B. Bartle.

80. **Bright's Disease.**—Goltman reports several cases of decapsulation. He thinks it is indicated in any form of chronic Bright's disease in any case where the patient has at least a short lease of life before him. His own cases have been of the diffuse and parenchymatous varieties, but, according to Edebohls, the interstitial form does best. This seems paradoxical to him, but experience is the best guide. To get the most beneficial results the operation should be done when the heart and arterial system are not too much deteriorated. The better their condition, the better the prognosis.

83. **Intratracheal Medication.**—McKinney advocates intratracheal medication in severe catarrhal conditions, using mild guaiacol solution daily. A few cases are reported, taken at random from a large number, showing, he thinks, how beneficial this method of direct medication is in catarrhal affections of the lower respiratory tract.

85. **Cancer of the Stomach.**—This article by Arneill covers the subject of stomach analysis and the diagnosis of gastric cancer. He says the persistent absence of HCl, the presence of lactic acid, long bacilli, yeast and retained food, with tumor and cachexia, in the vast majority of cases mean carcinoma. Even without the tumor, the diagnosis is justified. Positive diagnosis in the early stage is impossible. In an obscure digestive case which repeatedly shows an absence of free HCl and in which pernicious anemia has been excluded by careful blood examination, which continued to grow worse under good treatment, exploratory laparotomy should by all means be urged for diagnostic and, if indicated, for therapeutic purposes. He remarks on the failures of laboratory diagnosis in some of these cases, and thinks that, perhaps, the younger generation of physicians is apt to overestimate the value of such methods, while the older class minimize their importance.

90 Tubercular Kidney: Symptomatology and Diagnosis. Caspar W. Sharples.
91 **The Surgical Problem in Prostatic Hypertrophy.* (Concluded.) George W. Hawley.

91. **Prostatic Hypertrophy.**—Hawley's theory of the relief of prostatic hypertrophy is that it is not the prostate, but the adjacent urinary tract that demands relief. The trouble is due to displacement of the outlet and floor of the bladder from enlargement of the retro-urethral portion of the prostate. The only way to relieve the condition is by correcting the displacement, and the logical mode is by reduction. This is shown by the fact that operative methods improve urination by virtue of their power to reduce this displacement. While some of the methods employed partially or even completely accomplish reduction with comparative safety and others reduce the displacement at considerable risk, none does so with both safety and success. The problem being a simple mechanical one, reduction based on anatomic and mechanical rules should be the safest and best. His own method here suggested, and as tried on the cadaver, is to make Zuckerkandl's bi-ischial perineal incision, exposing the bulb of the urethra and the posterior half of the perineum, releasing the support of the latter by dividing the recto-urethral muscle just behind its attachment to the bulb, allowing the rectum to drop backward. The levators were then divided, enlarging the operative field, and the prostatic sheath opened along the under surface of the prostate from the apex to the base, separated from the lateral and undersurface of the retro-urethral prostate by the finger. After freeing the sheath the prostate was dislocated downward, and a section removed from the outer and lower portion of each lateral lobe. In each case operated on the reduction seemed to be complete. The retroprostatic pouch was obliterated, and good bladder drainage restored. In each case the urethra, bladder and ejaculatory ducts were uninjured, and enough of the prostate remained untouched to perform its functional purposes in all probability. He thinks this method is appropriate in early cases before the urinary tract has become infected and disorganized, because it can be done as an aseptic operation; because the urinary organs are uninjured, and the operative risk is small. The extent of operative interference required can be judged according to the conditions. He believes that this would be more effective than prostatectomy and less severe a procedure. The harm of removing the perineal support in the male is unknown, and is probably *nil*. The support of the bladder floor, following this method, would be maintained by the portion of the retro-urethral prostate remaining, and the cicatrix, filling in the perineum, would be low.

1. **Ectopic Pregnancy.**—The importance of early operation in ectopic pregnancy is pointed out by Herman, who thinks that even the inexperienced in surgery who is posted as to antiseptic methods should not hesitate to operate in emergencies, and especially in the case of great intraperitoneal bleeding. In the case of tubal mole, absorption usually takes place, but the danger of removing one is far less than that of leaving it. As regards the operation, he prefers the vaginal method as avoiding shock and exposure of the intestines. If the case passes to the second half of the pregnancy the danger diminishes. From the end of the first half of the ectopic pregnancy until the beginning of suppuration, the patient is in practically no danger. When spurious labor takes place the placenta usually becomes thrombosed and the danger of operation is lessened, but we can not tell how soon this may occur. When suppuration is begun, however, as indicated by the presence of fever, there should be no delay. The results of operation under such conditions ought to be as good as under those of abdominal operations generally. In case the child develops in the broad ligament it may be best to open the sack by a vaginal incision, thus avoiding infection of the peritoneum; the placenta need not be removed. Herman does not, however, advise vaginal operation unless it is certain that the tissues between the vaginal canal and the fetus are thin and that one end of the fetal ovoid points downward; still less if there is doubt as to the diagnosis.

2. **Abdominal Operations During Pregnancy.**—Thring concludes from his experience that all cases of acute infective diseases during pregnancy involving either the appendix, the tubes, the gall bladder or the bile ducts, should be treated as if the pregnancy did not exist. In this way we act in the best interest of the patient and their unborn children. Three cases are reported.

**4. Forcible Dilatation of the Cervix.**—Kerr states his views as regards Bossi's or Frommer's dilator as follows:

1. When the cervix is obliterated and the os will admit the dilator without difficulty, dilatation can be carried out in about twenty-five minutes, and there will be little or no laceration.

2. In cases where the pregnancy has advanced to or near term, even although the cervix is not obliterated, dilatation may be accomplished with comparative safety to the cervix, provided care, time and patience are expended in the operation.

3. In cases of early pregnancy with the cervix unobliterated there is a decided risk of extensive lacerations, even though the greatest care is taken.

**5. Gout.**—Chalmers Watson has utilized a case of gout occurring in the barn-yard fowl as bearing on the question as to the toxic principle and factors of the disease. This paper is illustrated with microscopic sections, and the conclusion he reaches favors the theory of an infection by bacteria or their products. He thinks that the clinical features of gout in all its forms are explained best by this theory which does not, however, by any means diminish the importance of the attention to dietetics in the treatment of the disease.

17* Tuberculosis of the Tonsils in Children. L. Kingsford.
18* Preliminary Note on the Prophylactic Action of Garlic against Tuberculous Diseases. Giulio Cavazzani.

**10. Electrotherapeusis.**—Owen thinks that much of the present literature of electrotherapeutics will be relegated to obscurity, but that there is a certain residue of established facts. He mentioned as included in this, the work with the *x*-rays, the subject of phoresis, which he thinks has yet to be developed, and the part that electrotherapeutic work has played in bringing about a fuller consideration of the physical forces which have to do with the intimate life of the cell.

**11. Sterility.**—Horrocks reviews the whole subject of sterility, showing the essentials of fecundation; a living ovum and spermatozoon which shall meet and coalesce in a suitable place and that the ovum after impregnation shall be in a healthy uterine cavity, where there is nothing to prevent its developing. As regards treatment, he thinks that many cases can be left alone, at least until sufficient time has elapsed to demonstrate the absoluteness of the condition. Spare diet and plenty of exercise will favor fertility, and if the patient has not been healthy suitable tonics may be given. Change of climate and environment has also been beneficial, and if there is any suspicion of specific disease the proper treatment should be advised. Local diseases of the genitals, such as ovaritis, endocervicitis, etc., may call for special measures. Regular natural habits are mentioned as also essential. It should be remembered that in a certain proportion of cases the sterility is on the part of the husband, and this matter should also be investigated.

**13. Kelly's Method of Cystoscopy in the Female.**—Wilson advocates Kelly's method of cystoscopy of the female bladder with air dilatation, as a valuable diagnostic method. It often prevents an erroneous opinion and frequently renders more definite a partial correctly formed conclusion.

**15. Deafness from Chronic Ear Disease.**—Watson believes in a closer and more systematic study of all cases of deafness due to chronic non-suppurative middle-ear disease as leading to a reversal of the opinion generally held as to the absence of clinical indications of catarrh in the group of cases variously described as sclerosis of the middle-ear, atrophic catarrh, otosclerosis, etc. Cases seen only at rare intervals will not suffice. If the known facts of morbid anatomy and pathology of cases of chronic non-suppurative middle-ear disease are brought into line with similar facts in the pathology of other mucous membrane and joint structures the impression is forced on us that the different conditions described are only variants of one morbid process. In over 200 cases observed by him, in every case there was either a clear history of frequent colds in the head or, in patients who definitely declared they were not subject to colds, unequivocal evidence of an intercurrent catarrh in the course of the few weeks in which these patients were daily observed. They had not taken due notice of themselves. He has also called in comparative pathology and studied the conditions in deaf dogs. He believes that we have in all cases to do with local reaction to bacterial invasion by way of the eustachian tube. We must also bear in mind the possibility of infection by means of the blood, which probably is a factor in many cases.

**17. Tuberculosis of the Tonsils.**—From the cases here reported and from the investigations of others, Kingsford deduces the following conclusions:

1. Tuberculosis of the tonsils, especially in cases with tubercle elsewhere, is fairly common, though the disease is usually latent. 2. Tonsil tuberculosis may be primary, and, indeed, the only seat of the disease in the system, though this is rarely the case. 3. The usual method of infection is by the blood stream in children from an older focus elsewhere. 4. Infection may also occur by the sputum in children. 5. When the tonsils are tuberculous the corresponding cervical glands become affected, and, 6. sometimes where it is probable that the infection entered through the tonsils they were quite healthy, but the adjacent cervical glands were tuberculous.

**18. Garlic in Tuberculosis.**—Alluding first to a former paper in which he had published the favorable results obtained in treating pulmonary phthisis with garlic, Cavazzani reports the results of experiments of garlic feeding of guinea-pigs. In eight guinea-pigs he insufflated dried and powdered tuberculous sputa into the larynx and kept the animals two days longer in a room impregnated with the same powder. Two guinea-pigs were kept as controls, while three of the remaining six were fed with one grain daily of garlic juice for a fortnight, and the other three received the same quantity for about three months altogether, then the animals were killed. The two control cases were tuberculous throughout the abdominal organs and the lymphatic system and the *Bacillus tuberculosis* was isolated. In the bodies of the three animals which had been treated with garlic for a short period he found from ten to twenty tubercles in the liver and spleen. Microscopic examination did not reveal the bacillus but showed the presence of young connective tissue in the tubercles. In the other three that had been treated longer with garlic, no tubercles were found after the most minute examination. While the small number of experiments prohibits the drawing of conclusions, Cavazzani says that if further experiment in this line should bear out these results and prove that guinea-pigs at least can be prevented from contracting inhaled tuberculosis, it may suggest the possible discovery of a treatment for the human species.

40 Répartition de la maladie du sommeil dans le Gouvernement général de l'Afrique occidentale française (sleeping sickness). Kermorgant.

37. **Organ Treatment of Nephritis.**—Renaut explains his conception of the mechanism by which the soluble and dialysable preproduct of the kidney secretion is elaborated. He regards this preproduct as a sort of antitoxin, and as antitoxin is not destroyed or modified in passing through the digestive tract, he believes that it is possible to supply the system with this preproduct or antitoxin in cases in which its production is interfered with by morbid conditions in the kidney. He and his pupils have established the existence of what he calls grains of segregation which accumulate in the supranuclear region of each epithelial cell in the convoluted tubules. These are accepted as the preproducts of the secretory activity; they include figured and spherical as well as fluid elements. If the convoluted tubule is dissolved in physiologic salt solution these yellowish, refracting bodies are plainly visible, resembling the grains of segregation of a serous gland, such as the parotid. They stain well with neutral red. He concludes from his researches that ingestion of these preproducts is an efficient remedy for nephritis. He gives the particulars of three typical cases out of a large number thus treated since last March. The results are tabulated and apparently confirm his assertions that this method of treatment has a rapid diuretic effect, and is one of the most active and effective yet known, even relieving the kidney in extreme anemic edema. When sufficiently prolonged it restores urination to normal and keeps it there, without having the slightest unfavorable action on the diseased kidney. It invariably reduces the proportion of albumin eliminated by the insufficient kidney. The only untoward effects observed from its prolonged use are occasional subtoxic symptoms (urticaria, sweats, slight gastric disturbance), but all are trifling. The process of disintoxication proceeds progressively and regularly, without mishap of any kind. Arterial hypertension and the tendency to passive dilatation of the heart have always receded under its influence when kept up long enough. He urges its early use in all cases of nephritis as an adjuvant to the usual measures, when the latter are not accomplishing all that could be desired. He prepares the remedy by chopping two or three fresh kidneys (pigs'), rinsing well to remove all the urine that may be still clinging to them. He then grinds the chopped organs and mixes them with 450 c.c. of a 7 per 1,000 salt solution which does not dissolve the grains of segregation at once. After thorough mixing, the dish is placed on ice for four hours and the supernatant fluid is then decanted and taken by the patient in three or four doses during the twenty-four hours. This maceration of the kidneys has no unpleasant taste, but to overcome any possible repugnance he orders it to be taken from a cup and a tablespoonful of tepid julienne soup added. After taking this maceration, prepared fresh every day, for ten days, it is suspended for five, which avoids the slight symptoms of subintoxication above mentioned. They indicate that the remedy is very powerful and similar in its action to that of therapeutic serums. The cases he describes in detail include one of chronic mixed nephritis, one of the interstitial type and one of cardiac albuminuria with cardiac kidney. The particulars are given in detailed tables and the prompt and enduring benefit derived from persevering use of the kidney maceration seems to be unmistakably apparent.

41 and 42. **Surgical Treatment of Perforation of Stomach.**—Brunner reports one patient saved by operative intervention out of 6 patients operated on. All such cases in which no operation was performed terminated fatally. The interval ranged from sixteen to thirty hours. In the consequent peritonitis he generally found polyinfection with streptococci and colon bacilli predominating. He was able to cultivate also some anaërobic bacilli. He further reports numerous experiments with injection of human stomach content into rabbits. Comparatively large amounts of acid gastric juice were tolerated without inflammation. An amount of 4.5 c.c. was tolerated always without reaction; he injected as much as 40 c.c. in some of his tests. Thirty-three of the 44 rabbits thus inoculated survived. Injections of stomach content in which gastric juice was lacking almost invariably induced symptoms of peritonitis within three and three-quarter hours. Bacteriologic tests of the stomach content showed much less bacteria in the stomach content in cases of pronounced motor disturbances accompanied by hyperchlorhydria than with deficient or missing gastric juice secretion. Surgical intervention, in his experimental research, resulted more favorably the earlier it was undertaken after the perforation. He is convinced that stomach content containing hydrochloric acid is much less dangerous from the standpoint of infecting the peritoneum after perforation than when there is little or none of the acid. His experience also confirms the advantages of multiple drainage after suture of a perforated ulcer, draining both at the sides and over the symphysis.

45. **Wounds of the Thorax.**—Borsziky's experience impels him to the view that expectant treatment of injuries of the lungs does not afford such bad results and radical intervention does not afford such good results that the latter method of treatment should be preferred to the former in all cases. More than 342 stab or firearm wounds of the thorax have been treated at the Ofen Pest clinic during the last ten years. All but 4 recovered out of the 42 stab wounds and all but 11 of the 89 firearm wounds.

46. **Treatment of Wounds on Biologic Principles.**—Ibrig remarks that we have no means to arrest nor to attenuate already established infection in a wound which does not at the same time destroy or reduce the vitality of the living tissue cells. The latter are the sole protecting agents, and everything should aim to favor them in their vital task of combating the infection. Anything that tends to reduce their vitality arrests the natural defensive processes of repair and promotes the infection, as the latter thrives best on degenerated cells. For

these reasons he rejects sublimate and carbolic acid, and devotes his attention to removal of all devitalized tissue, mechanical cleansing of the parts and keeping germs away from them. He prefers a solution of CaCl .03 per cent.; $NaHCO_3$ .04 per cent. and sodium chlorid .9 per cent. This aids the physiologic processes without impairing the vitality of the cells.

47. **Osteotomy in Genu Valgum.**—Since 1878 there have been 172 operations performed at von Bruns' clinic on 138 patients on account of genu valgum. In the 147 linear supracondylar osteotomies the operation was done on both sides in 29 instances. The remote results in 22 cases have been so encouraging that this operation may be regarded as ensuring very good results, both from the functional and cosmetic points of view. Radiography shows that the desired result is attained more completely the more plastic the bones at the time. A modification of Macewen's technic is preferred, using a small chisel and working from the inner aspect. Constriction of the limb is not necessary. The operation concludes with fracturing the external corticalis by leverage in such a way as to increase the outward angle. No untoward effects were noted in any instance.

48. **Thrombosis and Embolism After Laparotomies.**—Albanus reviews the 53 cases of thrombosis which occurred at the Hamburg Hospital in six years in the 1,140 laparotomies. Pulmonary embolism followed in 18.9 per cent. of the cases. In 26 out of the 53 the operation had been undertaken on account of a tumor; in 18 for a suppurative process, and in 10 for appendicitis. Almost 50 per cent. of the cases of thrombosis were followed by embolism, that is, in 23, and 10 of these terminated fatally. Most of the subjects were between 31 and 40, and the majority were women. The percentage was thrombosis in 4.64 per cent. of the 1,140 laparotomies. In 2 per cent. there was serious pulmonary embolism. When the latter has occurred treatment should aim to prevent infection from septic air, and further embolism by absolute repose. When thrombosis is noted, everything tending to excite the heart and all mechanical influences should be avoided. In the above cases the operation had been very protracted in more than 50 per cent. In only a few instances was more than 50 gm. chloroform used. The veins in the left leg seem most predisposed. Preceding heart disease had been noticed in 7 cases.

49. **Surgery of the Stomach.**—In this article Garré's technic, accepted indications and results are described in detail, with a review of the literature. The material embraces 109 cases of cancer operated on and 50 not, with 63 benign stomach affections operated on and 30 unoperated ones. He operates in case of an ulcus when there is suspicion of cancer or perforation, in case of a repetition of acute hemorrhage or constantly recurring smaller ones, and when three systematic "ulcer cures" have not afforded appreciable relief. Also in case of extreme cicatricial constriction of the pylorus, in severe gastralgia from adhesions or ulcer and atonic conditions of the stomach, especially with pronounced dilatation of the organ. He prepares the stomach with a preliminary five to eight days' course of light diet, with nutrient enemata and injections of salt solution if needed. In case of carcinoma the stomach is given a daily rinsing. He prefers ether, and adds a few drops of ol. pini pumilion. to reduce the secretions, giving 1 to 2 cg. morphin half an hour to an hour before long operations, ice and cold tea soon after the operation, and milk the second day. He lays great stress on immediate saline infusion and rectal injection. The article concludes with a tabulation of similar statistics from 15 other clinics.

52. **Hygroma of Deep Trochanteric Bursa.**—Lipffert has observed 3 cases recently at Tübingen. In 2 the hygroma was of tuberculous origin as in 116 others on record; in 7 the affection was of traumatic, and in 1 of rheumatic origin. One of his patients was a man of 56, with two large tumors of this kind. Lipffert emphasizes the necessity for total extirpation.

53. **Accidents from Agricultural Machines.**—Honsell analyzes 176 cases, and urges the necessity for more and better protecting devices against accidents from feed-cutters, etc. He also remarks that the place where the machine has to stand may also be one of the factors in such injuries.

54. **Study of Peritonitis.**—This extensive monograph, with its wealth of details and practical suggestions, is too comprehensive for a brief summary.

61. **Study of Scarlet Fever.**—Jochmann's research revealed the presence of streptococci in the blood of 25 out of 161 scarlet fever patients examined in the clinic. He also found streptococci in 75 per cent. of the scarlet fever cadavers examined. On the other hand, he encountered cases in which it was impossible to discover streptococci in the blood, tonsils or elsewhere in the living subject or the cadaver, especially the fulminating cases. He infers that the streptococci play an important part in the evolution of scarlet fever, but that they can scarcely be the true causal agent. The lesions and symptoms induced by the streptococci frequently overshadow the true scarlet fever process, but to date nothing is on record which establishes their etiologic connection with it. In nearly every instance he could trace the mode of entrance of the streptococci into the blood from the necrotic tonsil or soft palate into the submaxillary glands and thence into the general circulation. He never found any streptococci in the blood the first or second day of the disease. When streptococci are found in the blood the child has only a day or two to live—according to his experience. Streptococcus infection was not responsible for the nephritis in a number of cases in which it developed during the third week.

63. **The Normal Pylorus and Phantom Tumors in Abdomen.**—Cohnheim calls attention to the possibility of palpating the normal pylorus in certain subjects, usually those in whom the muscles are relaxed or where there is much emaciation. The subject lies horizontally, relaxing the epigastrium as much as possible, and drinks a glass or two of water. In favorable circumstances it is then possible to see the pylorus protrude, forming a tumor as large as a walnut, which travels upward two or three finger-breadths and then vanishes. When the phenomenon is not visible it can generally be palpated or the sound of the fluid passing through the pylorus be auscultated. There is no pain, and as the subjects grow fatter the phenomenon can no longer be detected. In 1 of his 16 subjects the normal pylorus was permanently palpable, owing to its large size. In general, however, a permanent lump at the pylorus indicates malignant disease.

64. **Influence of Various Substances on Gastric Secretions.**—In order to eliminate the influence of taste, appetite, etc., the substances tested were introduced into the stomach through a

stomach tube. Neither water, carbohydrates nor fats induced any appreciable secretion of gastric juice, but this always followed introduction of albuminoids. The latter are, therefore, the exclusive direct stimulators of the gastric juice secretion.

69. **Pathogenesis of Aneurism of Aorta.**—Six pages are devoted to the bibliography and nearly seventy to a review of it and discussion of 35 cases personally observed. The conclusions may be summarized almost in the one word: syphilis.

71. **Atropin in Case of Incarcerated Hernia.**—Hagen is an advocate of injecting belladonna or atropin when gentle taxis shows that the hernia is irreducible. He then waits one hour and applies gentle taxis once more. If it fails, he repeats the dose of the above. If two or three of these hourly doses fail to produce the desired effect he then operates, not waiting longer than six to eight hours at most. Atropin has proved particularly useful in elderly patients, saving them an operation. He describes 19 cases out of his experience with 41 during thirty-nine years, to confirm his claims as to the wisdom and efficacy of the above line of treatment. His experiments on animals have amply established its harmlessness. He prefers the extract belladonn. in the proportion of .1 to 10 or atropin sulph. in the proportion of .01 to 10. The first dose is usually .5 c.c., which may be repeated or doubled for the second dose an hour later.

77. **Relations Between Endothelial Cells and Anthrax Bacilli.**—Behring has recently announced in his *Beiträge* (December, 1903) that he has established a remarkable selective action on the part of the infectious substance circulating in the organism. The cells floating in the circulating medium are not the only bearers of the antitoxin, but certain fixed cells also possess this property of producing and storing the antibodies. Furthermore, this property is in the highest degree specific for certain kinds of cells and not for others in relation to a specific virus. For instance, the antibody for tetanus toxin is exclusively to be found in the ganglion cells of the nervous system. This discovery throws new light on the processes of intoxication in general, and the deductions from it have already been amply confirmed by experimental research conducted at Marburg. It has further suggested new improvements in the technic of artificial immunization by which the infectious process can be so guided and controlled that it is not only entirely harmless for the animal but enables the immunizing to be more complete and the production of antibodies materially augmented. He has established, besides, that the affinity between the tetanus toxin and its antibody produced in the ganglion cell does not explain all the phenomena observed after inoculation with tetanus toxin. A third agent must be present by which connection is established between the toxin and the intracellular antibody, as the cells of a battery do not generate electricity until they are connected by a conducting medium. In the living organism the part of the conductor is played by a substance in solution in the axis-cylinder, which serves as a conductor between, to transmit the stored-up energy in the tetanus toxin to the antibody fixed in the ganglion cell. He calls this intermediate substance "C" (conductor). The present article gives the details of the research undertaken to locate the site of the production of the antibody for anthrax bacilli. The results have established that the antibody for anthrax virus is elaborated in the endothelial cells. The conductor in this case he assumes to be a colloid solution of the antibody which exists normally in the intravascular fluids and intracellular tissue juices. The article is accompanied by colored plates to show the various phases of the production of the antibody and its passage into the circulating fluids in a colloid solution after oxyphile degeneration. The blood then acquires the property of agglutinating the bacteria which have induced the oxyphilia. This is evidently the result of specific attraction and a ferment-like, reciprocal action between the animal cell plasm and the vegetable bacteria plasm.

78. **Polyvalent Antistreptococcus Serum in Scarlet Fever.**—Bokay tried Moser's serum treatment in 12 cases, and was very favorably impressed with the results. No ill effect on the kidneys was apparent in any instance.

80. **Statistics of Inflammation of the Cecum.**—Villaret compares the statistics on this subject during the last twenty-seven years, as published by the German military authorities. He finds that all abdominal affections have become less frequent by 44.5 per cent. On the other hand, inflammation of the cecum has increased by 70 per cent.; liver affections have decreased by 64 per cent.; peritonitis by 70 per cent., and chronic stomach affections by nearly 80 per cent. The apparent increase in appendicitis and allied affections is thus merely the result of more careful differentiation.

82. **Treatment of Severe Postpartum Hemorrhage.**—Fritsch commends the advantages of his method of treating severe cases. He massages and pushes the uterus on and above the symphysis pubis and packs the space left with cloths or cotton from the rear, binding them tight with a roller bandage around the abdomen. The abdomen is thus pressed into a funnel shape. The body of the uterus rests on and above the symphysis, and its bleeding walls are pressed so tight together that there is no room for further hemorrhage. All the manipulations are extravaginal, and require no preliminary disinfection. Another method is to close the labia with one hand and push the vulva vigorously upward, exerting counter-pressure with the other hand, for half an hour.

90 Ueber die Erweiterung der Cervix mittels Metal-Dilatatoren. R. Katz.
91 *Ueber Salizylsäureglyzerinester (Glykosal). H. Ratz.

85. **New Sphygmograph.**—The principle of the instrument is similar to that of Gaertner's pulse controller described and illustrated in these columns on page 527 of the last volume. The pulse wave is registered in a magnified projection and a curve can be obtained in a few minutes, affording invaluable information in regard to the pulse. It may be expected to be small when the arteries are naturally narrow or inelastic, when the tonus is high or the systolic maximal pressure is low. The latter depends on the average blood pressure and likewise on the amount of the variations in the pulse.

86. **Lung Narcosis.**—Kuhn here suggests and commends his method of intubation through the nose or mouth deep into the throat as a means of introducing the anesthetic directly into the lungs. By this means it does not come in contact with the throat or nose, and reflex action is eliminated. Much smaller amounts are required, and there is no vomiting.

87. **Treatment of Tropical Dysentery.**—Köhler of Caracas, Venezuela, has derived great benefit from an infusion of cortex granati, cortex simarubæ and Campechy wood. They are used alone or in combination by the native physicians, and the failure of the classic methods of treatment he had learned at home, compelled him to try this South American remedy. Improvement was always marked within twelve hours, and he

never witnessed any untoward effect or intolerance in hundreds of cases thus treated. Water is poured over the roots broken up into small pieces, and the dish is set in the sunshine. It is ready to use by the end of the day. One tablespoonful is taken every twelve hours, with a daily injection of a quart of sterilized water. No food is allowed but boiled milk.

89 and 91. **Glykosal in Rheumatism.**—Bloch and Ratz in a following article extol the efficacy of this glycerin ester of salicylic acid. Bloch asserts that if it does not cure the pain the latter is certainly non-rheumatic.

97 *Curability of Carcinoma. R. Lomer (Hamburg).—Zur Frage der Heilbarkeit des Karzinoms.

92. **Pathology of the Newly-Born.**—Among the cases described by Hammer are 3 in which the death of the infant during or immediately after birth might have proved puzzling in a forensic case. In one, degeneration of the heart muscle was found and in another indications of a chronic inflammation of the placenta. In the third, nothing could be discovered, even with the microscope, in the fetus or placenta to which the immediate death could be attributed. A case is described in which an angioma cavernosum in the liver of a seven days' infant was discovered only with the microscope. In the case of the cyclops described, the infant bore no other trace of malformation.

94. **Combination of Tuberculosis and Carcinoma.**—Wallart has observed 3 cases of this combination, and reviews 54 works that have been published bearing on the same subject. In only one of his 3 cases were the two affections so strictly localized and so remote that the coincidence must have been casual.

97. **Curability of Cancer.**—Lomer's article has been already mentioned in these columns, page 207. He has found recorded in the literature 213 cases of carcinoma treated by electro- or thermo-cauterization in which there had been no recurrence after a minimum of two years; the interval was more than five years in 149 cases. This list includes a large number that had been previously branded as inoperable, and the success of his intervention surprised the operator, who had applied the actual cautery merely *ut aliquid fiat*. Such instances establish the fact that the body is sometimes able to cope with the relics of a carcinoma focus. In certain cases fever seems to have co-operated in this favorable outcome. The facts observed suggest that a febrile course after a cancer operation or as a symptom of some accidental infectious disease or severe burn seems to have promoted the healing process. The successful results observed after inoculation with erysipelas, streptococci or malaria are probably due to the accompanying febrile temperature. He mentions the toleration of cancer subjects for extensive losses of blood, and the fact that robust, plethoric individuals seem the most predisposed to rapid recurrence. Profound changes in the composition of the blood seem to have a curative tendency in cancer cases. These premises suggest the possible efficacy of serum treatment with an anticancer hemolytic or epithelium serum. Researches in this line are now under way, but Lomer says that they have not progressed sufficiently for publication as yet. The aim of treatment should be to induce in the organism conditions similar to those that prevail during the natural healing process when the body is annihilating the relics of a cancer focus. If cases in which this has occurred are studied more closely, it may be possible to discover some of these conditions and reproduce them artificially. The article concludes with Lomer's own experiences and statistics. Among the cases he describes is one of a recurring cicatricial mammary cancer. One-half of the new growth was extirpated; the remaining half was treated by a row of injections of his epithelial serum around it, as also an enlarged gland in the axilla. Both entirely retrogressed under this local treatment. Possibly any other serum might have been as effective, he says, but this and other cases establish the possibility of retrogression of a cancer. He outlines his theoretical plan of treatment as: 1. Systematic, repeated thermocauterization of every suspicious point in the cicatrix after extirpation of operable growths, and repeated applications in the inoperable cases. The patients must be supervised at six-week intervals at farthest. 2. Local applications of heat, sweat or light baths or girdles, and hot compresses after extirpation. 3. Energetic arsenic medication at once, supplemented by potassium chlorate. Commenced at once, arsenic offers better prospects of efficacy than after a recurrence has already developed. 4. Systematic irrigation of the vagina with a solution of potassium chlorate. 5. Injections for the purpose of inducing fever, possibly of staphylococcus toxin. This is merely an outline of treatment tentatively suggested by his research. His actual experience has repeatedly shown that after two or three applications of the searing iron a previously inoperable cancer could then be successfully extirpated. He has one patient cured for five and a half years after thermocauterization and extirpation of a cancer, and then of its recurrence. As he reviews the literature he notes that the occasional long survivals are always regarded as "accidental cures." The laws governing them have yet to be determined. Among the principal problems now pressing for solution are: 1. The action of epithelium serum and hemolytic human serum on visible carcinoma. 2. Whether leucocytosis occurs in cancer subjects, and especially whether it occurs independently of ulceration. 3. The behavior of cancer subjects in regard to soluble bacterial toxins (tuberculin, staphylotoxin). 4. Whether the causes of the lesser tendency of cancer subjects to acquire infectious disease are due to a histogenic, bactericidal or antitoxic immunity. 5. Whether the blood of cancer subjects contains toxic substances which induce cachexia (study of the isotoxins) and hemolytic and agglutinating substances in comparison with normal human blood. 6. Treatment of carcinoma subjects with organic and anorganic blood poisons (potassium chlorate, arsenic, pyridin or phenylene diamin), and, 7, behavior of the resistance of the red corpuscles of carcinoma subjects *in vitro*, in respect to various blood poisons.

**99. Fluids in Dietetics of Nephritis.**—It has been found at von Noorden's clinic that restriction of the intake of water had a favorable influence on the subsidence of edema. In both acute and chronic nephritis a moderate ingestion of water—not more than a quart and a half—had a more favorable action on the relations between the intake and output of water than a more copious supply. The elimination of nitrogen and the phosphates was not materially affected by it in acute nephritis and in case of contracted kidney. Restriction of the intake of water to less than 1,250 c.c. interfered with the elimination of these substances. It seems advisable, therefore, to interpose an occasional day of copious drinking in order to flush out these substances when, for any cause, the intake of fluids has to be restricted in general. If the kidneys are functionally insufficient or if there is no accumulation of material for the production of urine, there is no washing out of these substances when this is done. In cases of contracted kidney the albuminuria increases when the water is restricted, as a rule, but subsides again in time. This influence on the albuminuria was not noted in the later stages of acute nephritis.

**102. Formation of Antitoxin in a Case of Tetanus.**—The injection of tetanus antitoxin may prevent the toxin from combining with the cells, but it is powerless to neutralize the toxin already in combination with the nerve centers and other organs. This fact has been confirmed anew by the case described in this article. A woman of 29 succumbed in four days—notwithstanding energetic antitoxin treatment—to tetanus that developed consecutive to an abortion. Examination of the urine, cerebrospinal fluid, serum, spinal cord, liver, brain, kidneys, spleen and thyroid gland, showed an abundance of free antitoxin in the serum and urine, but the toxin was in such stable combination with the organs that large proportions of antitoxin were unable to neutralize it, even *in vitro.*

**104. Chemistry of Blood in Nephritis.**—In a case of parenchymatous nephritis, one of subchronic nephritis and one of secondary contracted kidney, examination of the blood showed a marked deficiency in albumin, as well as other abnormalities. The lack of albumin induces albumin hunger in the cells, which in turn causes a stronger current of blood through them and by reflex influence enhances the heart action, with consequent hypertrophy of the heart. The precipitin reaction in the cases mentioned showed that the globulin in the nephritic urine was mostly normal serum globulin.

**106. Acute Dilatation of Heart.**—De la Camp announces as the summary conclusion of his laborious research that acute dilatation of the heart after maximal physical exertion is never observed except when the integrity of the organ is already seriously impaired.

**108. Pancreas Affections.**—Lazarus traces the history of the pancreas back to Hippocrates and down to Oser's latest work on the subject in 1902. He discusses its topography, and emphasizes the facts that none of the arteries supplies blood exclusively to the pancreas, and that it does not lie between the sheets of the transverse mesocolon, as generally accepted, but rather above it, and between the sheets of the dorsal omentum, which is connected only secondarily with the mesocolon. He reviews the experiences at von Leyden's clinic, Berlin, and tabulates the data of 14 cases, with several cuts. The article is continued through the following number. He noted trauma in the etiology of 30 per cent. of the cases of cyst in the pancreas.

**113. Salt Metabolism in Nephritis.**—This article corroborates the new theories as to the transcendent importance of salt in the diet of certain forms of kidney disease. The elimination of phosphates and sulphates is not modified like that of the chlorids by the nephritis. There does not seem to be any parallelism between the amount of the urine and the percentage of salt in it. We have no grounds for assuming that the output of salt is proportional to the output of water, but the assumption is being confirmed that retention of salt influences the retention of fluids. The percentage of salt in the body fluids in case of edema remains at a constant figure. The percentage in the urine varies with the presence and amount of edema, diminishing as the latter increases and vice versa. Evidence to date shows that the retained salt is stored in the tissues as well as in the body juices. Evidence is also accumulating to show that the retention of salt is the result principally of disturbances in the circulation. This has been established in case of non-nephritic effusions. The amount of salt in the urine in general and during nephritis in particular, may serve as a standard for the severity of the disease. A larger proportion succeeding to retention may be regarded as always a favorable sign. A low percentage, especially when it can not be increased or only temporarily, indicates a more serious condition. The above facts suggest the necessity for expelling the retained salt as an important factor in the formation of edema. The salt can be washed out of the system in most cases by administration of diuretin and heart tonics. The clinical course of a number of cases of nephritis with edema is given in separate tables, proving the remarkable improvement liable to be derived from diuretin combined with digitalis or caffein. The heart tonics alone are able to increase materially the output of salt, and in all forms of nephritis particular attention should be paid to the heart, using heart tonics and other measures for strengthening the heart, with carbonated baths well to the fore. Likewise, in all forms of nephritis, particular attention should be devoted to the intake of salt. The ordinary .91 per cent. saline solution should not be used for infusion in these cases, but always a hypotonic solution, as Senator has already advocated for other reasons. The intake of water should be restricted only to an extent which does not interfere with the excretions and general forces of the organism. If restriction of the amount of water does not accomplish the desired purpose, then the intake of salt should be reduced and its elimination promoted by the above medication.

**114. Eliminating Capacity of Diseased Kidney.**—Mohr gives various tables of the clinical course in several cases of nephritis. Analysis of them shows in common a fluctuating elimination of water, salts and nitrogen, but the elimination of $NH_3$ and of the purin bases was good in each. One case was accompanied by considerable edema and retention of salt. Therapeutic administration of salt in this case was followed by a sudden and enormous elimination of salt, revealing the large amounts that had been retained. On the whole, Mohr accepts as the only fact yet positively established in this line that disease of the kidney may entail retention of any of the elements of the urine, and that the kidney eliminates certain of these elements easier than others. Whether this elective elimination resides in the kidney itself or elsewhere, or in the nature of the substances, is yet unknown.

122. **Study of Brain Gliomata and Central Optic Tracts.**—Two cases of *glioma* of the brain were observed at Tanzi's clinic and subjected to minute postmortem examination. The *findings are given in* 16 cuts, with careful analysis of the symptoms and pathologic anatomy. Righetti reviews the literature on the subject and finds 115 cases in which somnolence was mentioned as a prominent symptom of brain tumor. Classifying these cases according to the site of the tumor, he finds that the majority were located in or near the third ventricle and the hypophysis. This suggests a connection between the somnolence and the circulation at the base of the brain.

127. **Serum Therapy in Epilepsy.**—Catola gave Ceni's method of serum treatment of epilepsy a fair trial in 7 cases, but did not find it beneficial. He does not think it conforms to the phenomena of cell biology as we know them, but rather conflicts with our knowledge of these laws. Guidi has reported a severe case apparently benefited, but this improvement, Catola thinks, should be ascribed to the concomitant suppression of alcohol and meat.

130. **Pathology of the Cells of the Sensory Ganglia.**—Lugaro is editor of the *Rivista*, and his article has been running through several years (*V, Nos. 4, 6 and 9; VI, No. 10*, and VII, No. 3). It is profusely and beautifully illustrated with 145 cuts, and is based on both clinical and histologic research and experimentation. He epitomizes his work in the statement that the diverse morphologic types observed in sensory ganglia may be regarded as differing not only anatomically, but also physiologically. They are found in the same proportions in similar ganglia in other subjects and *animals* of the same species, and each responds with a specific reaction after section of the peripheral nerve. The typical reaction is central chromatolysis with displacement of the nucleus, but there are many degrees of these modifications. They are *manifestly* the indices of changes due to the exceptional trophic activity of the cell during the period of the regeneration of the injured nerve fiber.

138 *Traumatitcheskii *hydronephroz.* I. I. Ryaboff.

132. **Prolonged Alcoholic Hallucinations.**—A prolonged—almost chronic—stage of hallucinations is liable to follow after attacks of delirium *tremens*—echoes of the preceding disturbances. Sukhanoff and Vredenski had occasion to observe 33 cases of this category among the 4,813 *patients* at the Moscow psychiatric clinic. All but 3 were men. They describe the points in which this condition differs from acute *delirium* and *from* alcoholic melancholia and paranoia, and comment on its curability. Many of the patients become alarmed at the persistence of the "voices," etc., and abandon alcohol completely. Hereditary predisposition was evident in 96.55 per cent. of the cases. Less than 12 per cent. of the 33 cases were educated persons, the majority were day-laborers, farm hands, etc.

136. **Diabetic Coma.**—Orlovski gives in detailed and tabulated form the *analysis* of 3 cases of terminal diabetic coma. The average amount of urine uring the three preceding days and during the coma was 2,617 c.c. and 1,800 in one case; 5,126 and 1,100 in the second and 7,167 and 782 in the third, notwithstanding the large amounts of water *ingested* and injected. The specific gravity of the urine was slightly reduced. In the first case no sugar was to be found in the urine during this period; in the second case it averaged 9.3 per cent. during the three preceding days and 4.65 *during the coma*; in the third case it averaged 8.55 before and 10.75 during the coma. No albumin in urine in the first case and merely traces in the others during the coma, and none during the three preceding days. The pulse during the preliminary period averaged 118, and during the coma 130 in the first case; 78 and 100 to 140 in the second, and 94 and 114 in the third. The respiration averaged 43 in the *preceding period* and 47 *to* 28 during the coma in the first case; in the second, 26 and 22 to 24, and in the *third case* 18 *and* 17 *to* 26. *Diagnosis* of the diabetes from the composition of the urine would have been impossible in one of the cases if the *patient* had not been observed before *the onset* of the coma. His patients were young officers or government officials, 24 and 25 years old. Acetone was present in the urine in both periods in all cases, and aceto-acetic acid was present during the coma in each case, but not during the previous three to six days.

137. **Typhoid Suppuration in Ovarian Cyst.**—Zantchenko refers to 3 cases on record in which an ovarian cyst suppurated and the typhoid bacillus was found in the pus, accompanied by a diplococcus in one instance. The cysts were all of dermoid origin, but in a case he has personally observed pure cultures of the typhoid bacillus were cultivated from a pseudo-mucinous *cyst—the only case of the kind of which* he has knowledge.

138. **Traumatic Hydronephrosis.**—Ryaboff records the case of a lad of 12 who had been kicked in the left side by a horse. The entire abdomen was painful and the boy vomited, with blood in the urine, when first seen the second day, and symptoms of hydronephrosis developed by the twenty-fourth day. After the failure of all other measures, nephrotomy was performed about six weeks after the trauma. A mass of jelly-like substance was removed from the pelvis of the kidney, consisting mostly of fibrin. It was evidently the relics of blood clots and had plugged the opening into the ureter and thus induced the hydronephrosis. Complete recovery followed the operation which was supplemented by copious flushing of the pelvis of the kidney with a solution of boric acid, and drainage. He cites a somewhat similar case that has been published by Parker, although in this latter instance a stone was found in the kidney. In his case there was no stone, but the clotted fibrin would probably have entailed the formation of a stone in time.

## New Patents.

Patents of interest to physicians, Dec. 15 to 29, 1903:

747138. Disinfectant and making same. Joseph Choulet, Algiers, Algeria.
746791. Obstetrical forceps. Jesse A. Clifton, Orangeburg, S. C.
747157. Sphygmograph. Wm. H. Fahrney, *Chicago.*
746832. Sanitary syrup-receptacle for soda-water fountains. Fred H. Hecker, Chicago.
747068. Indicator for dilators. Carl G. Heynemann, *Leipsic,* Germany.
746841. Stopper for bottles for aerated waters or other liquids under pressure. Francis Iles, Budapest, Austria-Hungary.
747184. Formaldehyde fumigator. Robert W. Johnson, New Brunswick, N. J.
746872. Hernial truss. F. P. McElfresh, Jackson Township, Shelby County, Iowa.
746731. Formaldehyde fumigator. Seth M. Morris, Galveston, Texas.
746749. Nasal medicator. George E. Seidel, *Richmond, Ind.*
747247. Truss pad. Isaac B. Seeley, New York.
747359. Secateur. A. W. A. Barnard and W. G. Reid, Dunedin, New Zealand.
747364. Vaporizer for anesthetics. George L. Bennett, *Chicago.*
747713. Apparatus for dispensing hot beverages. Heber A. Hopkins, West Roxbury, Mass.
747444. Combined syringe and applicator. E. N. La Vetne, Kansas City, Mo.
747742. Anesthetic inhaler. *Edwin Marshall,* Warrensburg, Mo.
747634. Water bag. Harriette E. Peterson, Washington, D. C.
747525. Surgical apparatus. Belle R. Willis, St. Joseph, Mo.
748336. Abdominal bandage. Carrie Babion, *Chesaning,* Mich.
748068. Crutch. J. H. Hammond and W. Bridgewater, Leicester, England.
747972. Surgical operating frame. Rudolph C. Hoyer, Vicksburg, Miss.
748289. Collapsible stretcher. *Emanuel* Kottusch, Zurich, Switzerland.
748413. Disinfecting apparatus. F. C. Nye, Syracuse, N. Y.
748424. Hypodermic syringe. *Arno Schmidt,* Weimar, Germany.
748426. Combined body *brace* and truss. S. R. Shepard, Louisville, Ky.
748227. Atomizer. Ferdinand A. Smith, Los Angeles, Cal.

## Address.

### GENERAL PRACTICE A CONTINUOUS POST-GRADUATE CLINIC.*

EDWIN WALKER, M.D., Ph.D.
EVANSVILLE, IND.

Both the practitioner and the specialist are compelled to give attention to the whole science of medicine, and after all, they stand on common ground. The ideal practitioner must be quick to recognize the early manifestations of grave diseases which require the specialist's care, while the ideal specialist must as readily diagnose complications which may prove more serious to the individual than the disease he is called on to treat.

The specialist is also dependent on the practitioner for information concerning the ultimate results of his work. He should learn his successes and failures from the practitioner. for, after all, the test of any operation or treatment is the relief experienced by the patient. An operation, no matter how brilliant, is a failure unless it relieves or cures the subject, and the ultimate verdict must come from the family physician.

The general practitioner is first to deal with those cases which require the specialist's care, and on his diagnostic skill and management of the case frequently depends the future of the patient. Let him mistake panophthalmitis for a conjunctivitis, and treat it a few days with eye washes, and the best oculist in the land can not undo the mischief. A suppuration of the mastoid which has already involved the meninges, will baffle the skill of the best-trained otologist.

At a meeting like this, what better service can a specialist render than to familiarize his brother, the general practitioner, with the symptoms which should warn him of danger, and thus teach him to early recognize serious diseases, instruct him in the best method of management while under his care, and counsel him in the treatment of cases which come safely and properly within his province.

Much that has been said of the injustice to the general worker in his relation to the specialist has no foundation in fact. Every conscientious medical man holds the good to the patient as the paramount consideration, and would not undertake to treat him if he could be better cared for by a specialist. None can deny that technical skill is acquired by practice only, and it is impossible for the general worker to attain proficiency in every branch. Yet in many emergencies such skill is indispensable. I have found that those physicians who frankly acknowledge lack of skill in lines of practice unfamiliar to them, and who recommend the sufferers to seek other aid when it is best for them to do so, have held the confidence and respect of their clients. There is nothing more dangerous, in these days of enlightenment, than the assumption of knowledge one does not possess, for exposure is almost sure to follow with corresponding loss of prestige.

Nearly all the members of this association are practitioners, general and special; the men who apply the truths of our science to the relief of suffering humanity. To the student of science surrounded by the best conditions, we must leave most of the work of investigation and higher research. His discoveries come to us for their proof and final test—we are the supreme court—and their value is determined by the results we obtain.

While we give all honor to these workers, we have the satisfaction of knowing that many of the most important advances have been made by men in our class. Huhlings Jackson, by careful study of the form of epilepsy which bears his name, pointed out that there were motor areas of the cerebral cortex, and gave Ferrier the impulse to make the experiments which put cerebral localization on a sure foundation. Ephraim McDowell and Marion Sims, while humble practitioners, were the pioneers in modern surgical advancement.

I wish I had some new discovery or thought to offer you, for what dearer ambition has any of us than that he may add something new to the science we love. Alas! the good fortune falls to but few. The best I can offer is some thoughts which have aided me and formed the motive in my humble work. What I have to say is not new to any of you, and I am glad to add, the same impulses have dominated us all. The rank and file of the profession have been pushing forward to higher ideals, and the average ability of all classes of workers advances materially from year to year.

Mr. Augustus Thomas, the celebrated playwright, in presenting a toast, said he had thought much about what he should say, and had finally determined to express just one idea, and he thought in the roundup of the evening he would average up very well with the other speakers.

The special idea I want to express is the necessity of careful, accurate observation and study of your cases, and above all, the correct diagnosis of each one as a necessary requisite to advancement in your profession.

Experience is valuable in proportion as it is founded on accurate observation. If you incorrectly diagnose your case, how can you draw correct conclusions from your observations and treatment? If your premises are faulty, so also must be your deductions. I have often thought that the experience of the physician who does not thoroughly and thoughtfully study and diagnose tempt something entirely unfitted to your sphere. A method suitable to the student in the laboratory or a clinician in a large hospital would not be the one for the practitioner of the crossroads. Each must fit his methods to his needs. The practitioner remote from large centers must evolve his own system. He must have help; if his practice is large, an assistant or competent nurse should be obtained. It is my belief that in the near future the trained nurse will become in fact a clinical assistant, relieving the busy doctor of many details, as testing urine, stomach contents, and other minor manipulations. Even he who is so remote as to be denied these aids can generally find those in the community who can be taught to take much of the drudgery. Learn to save time and apply it to the essentials, leaving the details to others.

* President's address at the twenty-ninth meeting of the Mississippi Valley Medical Association at Memphis, Tenn., October, 1903.

## Original Articles.

# THE INFLUENCE OF RESECTION OF THE CERVICAL SYMPATHETIC GANGLIA IN GLAUCOMA.*

WILLIAM H. WILDER, M.D.

Assistant Professor of Ophthalmology, Rush Medical College, University of Chicago; Professor of Ophthalmology, Chicago Policlinic; Surgeon to the Illinois Charitable Eye and Ear Infirmary.

CHICAGO.

This paper does not pretend to be a treatise on the subject mentioned in the title, nor does it assume to give any positive conclusions as to the value of the operation of sympathectomy in glaucoma; for it may be said at the outset that, despite the study of almost all the literature on the subject in its preparation and the collection of published and unpublished data in this country, I feel that positive conclusions are not yet to be reached, and I can only offer this as a contribution that may possibly aid in future work.

I wish at first to express my sincere thanks to the ophthalmologists of the country who so generously responded to the letter asking for data concerning cases of excision of the sympathetic ganglia for glaucoma, and for the latest possible reports of the condition of such cases.

In this way it has been possible to secure records of almost all the cases of glaucoma treated by this means in this country. In several instances the reports seem so favorable that one is tempted to draw general conclusions, while in others the data are so meager or the time that has elapsed since the operation is so short that positive deductions are unwarrantable. Such reports would be more valuable if in every instance careful clinical records had been kept, together with charts of the visual fields. Nothing is more important in the study of chronic glaucoma than the condition of the peripheral vision, and such record in a number of these cases is lacking.

I desire, first, to present a detailed report of seven cases of sympathectomy for glaucoma in my own practice which are still under observation, two of which are rather recent. I shall then give an abstract of the records of cases of sympathectomy for glaucoma that have been done in this country, as they were furnished to me by the observers in answer to the circular letter sent out this spring. Many of these cases have already been published, but the observers have kindly sent me the latest possible report on the condition:

Case 1.—Chronic inflammatory glaucoma—right eye. Sympathectomy (no benefit). Iridectomy (improvement).

Felix H., aged 40 years. Entered Illinois Eye and Ear Infirmary April 29, 1901. Family history negative, and no previous history of eye trouble until April, 1898, when he lost the sight of the left eye by having it struck with a piece of hot brass. He could see shadows with it until one year before admission. Some three weeks after the injury to the left eye, the right became inflamed, and he states that he was unable to see with it for two or three weeks, and then he recovered vision. In the last two months he has noticed failure of vision, with occasional pain in the right eye. Halos have been noticed around a light. On admission R. E. V.=20/50 with Cyl.+1.50, 180°, slight improvement. Conjunctiva of right eye injected and there is engorgement of the ciliary vessels. Pupil moderately dilated and vertically oblong. Responds to light. T.+. Optic disc distinctly excavated, but no pulsation of the vessels. L. E. V.=0. Conjunctiva injected; pupil dilated, cataract. T.+1. No perception of light. Fundus not visible. Eserin, grains ii-℥i, was used three times daily, and the pupil became somewhat smaller and the tension less. For visual fields see Figure 1, which shows marked contraction in all meridians.

May 16, 1901, R. V.=20/70 with Cyl.+1.50, 180°, through stenopaic slit 20/50. Severe pain last night. A. c. shallow. T. +1. Pupil dilated 5 mm. In the afternoon of this day, under chloroform narcosis, Dr. F. C. Schaefer removed the right superior cervical sympathetic ganglion. Contraction of the pupil immediately followed, but tension was not lowered until several hours after the operation. At the time of the operation there was neither pallor nor flushing of the face, nor was there an increase of lachrymal secretion. Ptosis of right side was noticed after recovery of consciousness.

May 17, 1901. Patient comfortable, right pupil contracted. T. lower than before, but still +.

May 18, 1901. Considerable headache. Pupil contracted. T.+.

May 20, 1901. Considerable pain in wound and head. T. slightly +. R. V. =20/40.

There was some infection of the wound, but by June 7 it had completely healed and patient had no more pain and also no headache. The slight improvement in central vision continued at 20/40 and the tension was only slightly increased. The fields, however, showed no improvement.

June 13, 1901. Vision fell to 20/70, with an increase of tension. This was not controlled by eserin.

June 20, 1901. Tension has been elevated for one week and there has been occasional pain in the eye. Large iridectomy done upward.

June 22, 1901. Very slight reaction from iridectomy.

July 2, 1901. R. V.=20/100. Tension normal. No pain. Central vision began to improve, but occasionally there was slight pain in the eye and slightly increased tension.

From Aug. 2, 1901, to date of his discharge, Aug. 29, 1901, the tension remained normal and the eye was quiet. R. V. with Cyl.+1.00. Ax. 20°=20/30+. Visual fields were unchanged. See Figure 3.

Case 2.—Chronic inflammatory glaucoma. Both eyes. Rt., sympathectomy (marked temporary improvement). Iridectomy.

Edw. L. V., aged 62 years, entered Illinois Eye and Ear Infirmary June 29, 1901. No history of previous eye disease. History of rheumatism. Father became blind at the age of 70 years. Examination of urine shows nothing abnormal. About five years before patient noticed he would occasionally see rings of color around a light, but it was not until six months before admission that he commenced to have pain in his eyes, which he describes as dull, persistent and centering over the left eye. He has noticed a gradual failure of vision, and at different times a complete loss of vision in different fields. There is a history of an acute exacerbation three weeks ago, since which time he has had more trouble. Patient hyperopic. R. E V. with Sph.+5 00=20/100+1.

---

* Author's abstract of a paper read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks. The full paper appears in the Transactions of the Section, 1903.

Cornea clear, not anesthetic. A. c. shallow. Some circumcorneal injection. Pupil not dilated, responds feebly to light. T.+. Lens slightly cloudy. Disc deeply cupped with glaucoma halo.

L E V. with Sph +5.00 = Fingers at 5 feet in temporal field. Pupil normal in size T.+. Some opacity of crystalline lens. Disc deeply cupped. For fields of right eye see Figure 4. It was impossible to chart the field of vision of the left eye. Eserin, grains ii-ʒi, t. i. d., was used in each eye.

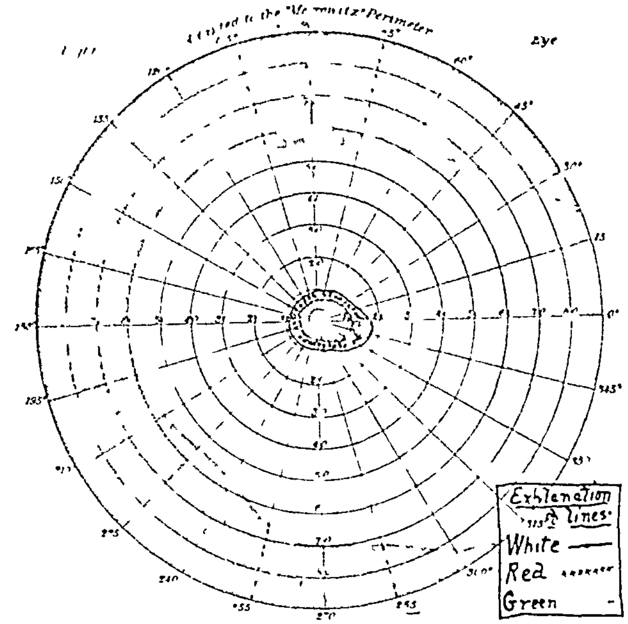

Figure 1, Case 1—Felix H, aged 40 Before sympathectomy. Chronic inflammatory glaucoma. April 29, 1901 Rt. eye V=20/50 T.+ Good illum obj 1 cm sq

Operation July 12, 1901. Under ether narcosis the right superior cervical sympathetic ganglion was removed by Dr. F. C. Schaefer. The operation was successfully and easily performed and the patient bore it well. Soon after the operation it was noticed that the right pupil was contracted, there was ptosis and the tension was about normal.

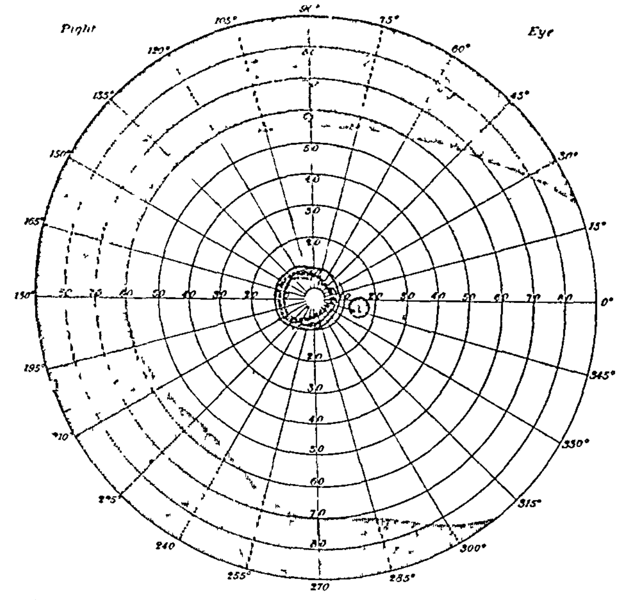

Figure 3, Case 1—Five weeks after iridectomy Chronic inflammatory glaucoma Aug. 29, 1901 Rt eye V=20/30+ T. n

July 16, 1901. R. V. with Sph.+5.00=20/50. Pupil small. T.+.

July 17, 1901. R. V. with Sph.+5=20/70. Pupil small. T.+. Wound in the neck healed by first intention and patient experienced no ill effects from it. Vision began to improve, although tension remained slightly increased.

July 30, 1901. R. V. with Sph.+5.00=20/40+. Fields increased (Fig. 5). Tension is also nearer normal.

Aug. 8, 1901. R. V. with Sph.+5.00=20/30. Tension normal. Field (Fig. 6).

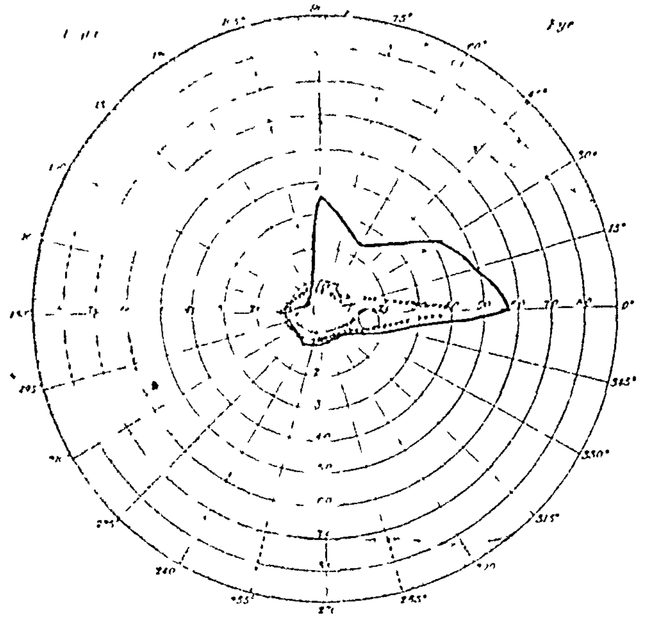

Figure 4, Case 2—Edw. V., aged 62 Chronic inflammatory glaucoma. June 29, 1901. Rt. eye V=20/100. T.+. Obj. 1 cm. sq.

Aug. 31, 1901. He left the hospital against my advice. T. n. R. V.=20/30. Field as above.

Oct. 26, 1901. Readmitted to the hospital. R. V. with glass =20/70. L. V. with glass=Fingers 6 in. Tension of right eye decidedly plus The impairment of central vision is probably due to increasing cloudiness of the central portion of lens. The left lens was much more opaque than when he left the house in August. The visual fields of the right eye had become markedly contracted, as seen in Figure 7. As the tension remained high I did an iridectomy on the right eye Nov. 14, 1901, followed one week later by an iridectomy of the left eye. Although the operation was easily performed and without accident or complication, it had the effect of causing

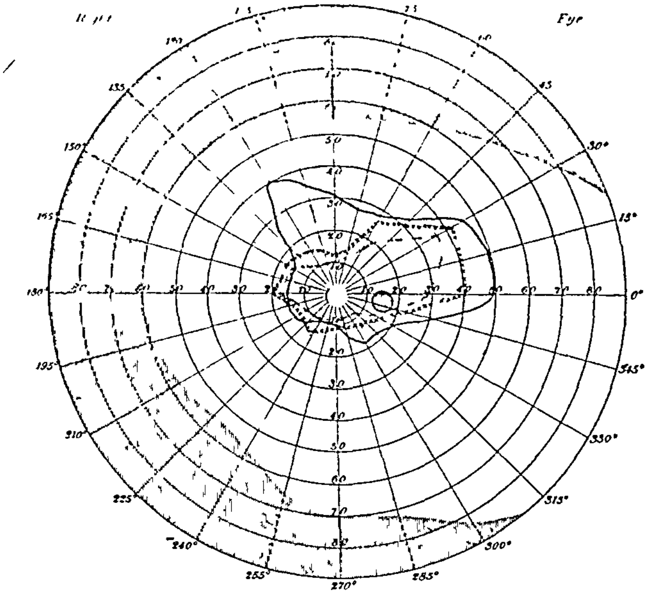

Figure 5, Case 2—Eighteen days after sympathectomy. Chronic inflammatory glaucoma July 30, 1901 Rt. eye V=20/40+. T. n. Obj 1 cm sq the opacity of the lens to increase more rapidly. The tension returned to normal and patient left the hospital Dec. 6, 1901. R. V.=15/200. L. V.=shadows. He promised to return as soon as the cataract in the right eye made him helpless, but although I have endeavored to find him, I have not seen him since.

Case 3.—Simple glaucoma, both eyes. Left sympathectomy, without benefit. Left iridectomy, with questionable benefit.

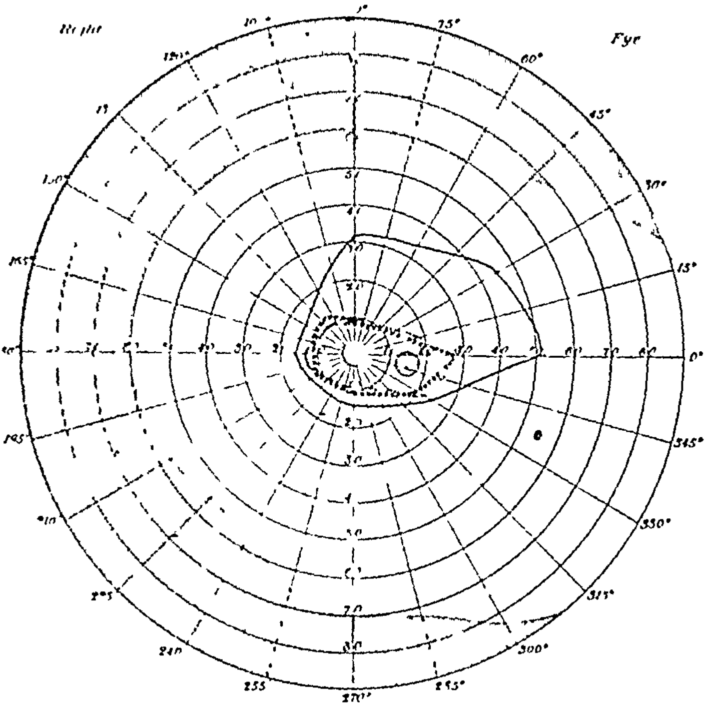

Figure 6, Case 2—One month after sympathectomy. Chronic inflammatory glaucoma. Aug 8, 1901. Rt. eye V=20/30. T. n. Obj. 1 cm sq.

Dr. John H., aged 46 years, consulted me Nov. 15, 1901, referred by Dr. A. E. Prince, Springfield, Ill. General health good. At the age of 20 he had granulated eyelids, from which he suffered for two years, recovering completely. No trouble of eyes since that time until January, 1901, when his eyesight began to grow dim, and he would occasionally see halos around a light with the left eye. These attacks of dimness of vision, during which he seemed to be looking through a "fog or haze," came on at intervals of five or six days, and lasted several hours. There was no pain, redness or tenderness of the eyes during these attacks or during the intervals. He noticed that his sight was usually clearer in the morning than in the afternoon. Four weeks before coming to me he consulted Dr Thompson of Indianapolis, who pronounced his case glaucoma and prescribed eserin, which he was using at the time. Condition at time of first examination, Nov. 15, 1901: R V. with Sph.+2.00⌣Cyl.—3.50, 180°=20/200. L. V. with Sph. +4 00⌣Cyl.+3.00 75°=20/200. He was wearing such lenses constantly. Both pupils small and somewhat irregular and do not respond to light. Tension of each +1.

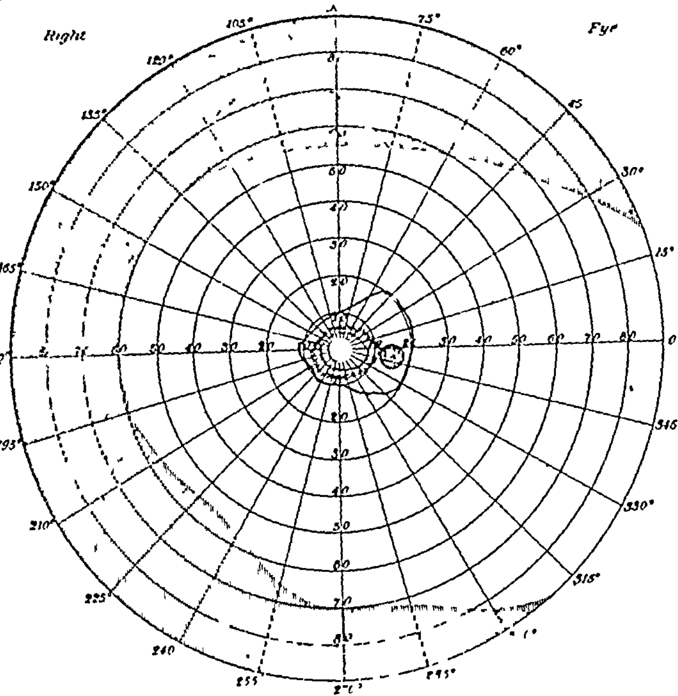

Figure 7, Case 2—Fourteen weeks after sympathectomy. Chronic inflammatory glaucoma Oct 26, 1901. Rt eye V=20/70. T.+1. Obj. 1 cm sq

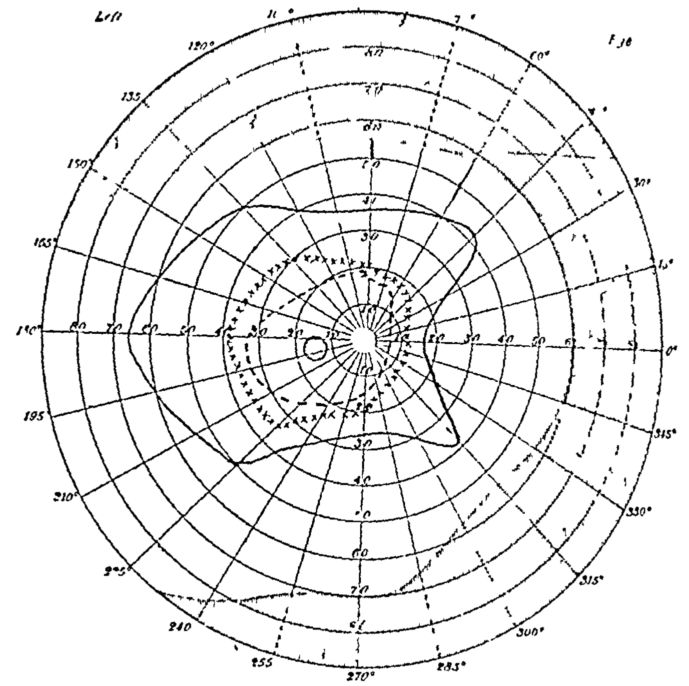

Figure 9, Case 3—Before sympathectomy Simple glaucoma Nov. 16, 1901. Left eye V=20/200 T+1. Obj. 1 cm sq

On discontinuing the use of the eserin for one day the pupils dilated moderately so that the fundus could be seen clearly. There was a deep glaucomatous excavation in each disc. The fields (Fig. 9), taken Nov. 16, 1901, showed marked contraction in the nasal region, that of the right noticeably so. The anterior chamber was about of normal depth. After discussing the question of operation with the patient it was decided to do a sympathectomy on the left side: Nov. 20, 1901, the left superior cervical sympathetic ganglion was excised by Dr. Schaefer at the Post Graduate Hospital under chloroform narcosis. The operation was successfully performed. Immediately after the operation the left pupil, which had been without eserin for two days and was mod-

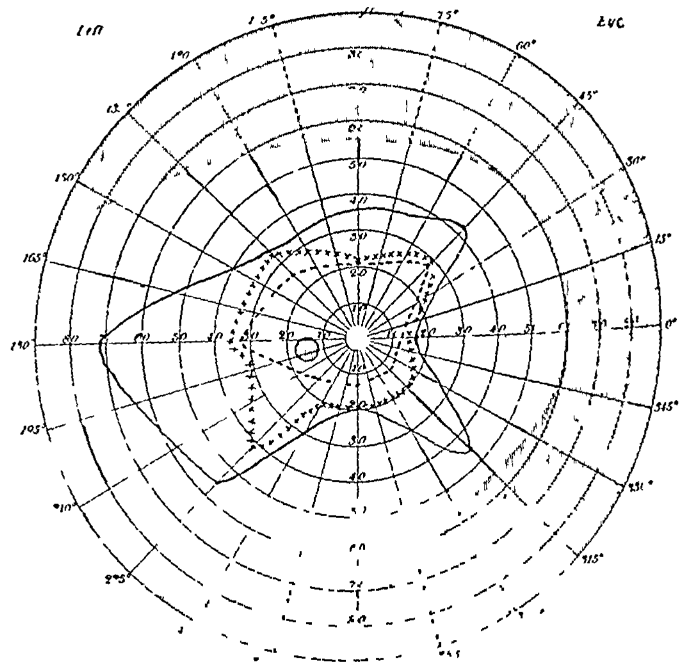

Figure 10, Case 3—Five weeks after sympathectomy Simple glaucoma Dec. 30, 1901 Left eye V=20/200 T n Obj 1 cm sq.

erately dilated, contracted, and the tension became normal. The patient recovered nicely from the operation, but had some sensitiveness of the left side of the neck and face and inability to raise the left arm and shoulder He was also quite hoarse, and this symptom persisted

Dec 1, 1901 L V. with Sph +4 00⊂Cyl +3 00 75°=20/200 T n, pupil small, ptosis of left Fields show no increase. R V. with Sph +2 00⊂Cyl —3 50, 180°=20/200 Pupil small from pilocarpin T n, sometimes +.

Dec 30, 1901 Condition same as on December 1. Color fields slightly enlarged (Fig 10). He left the city with instructions to continue the miotic and to report at once if his sight began to get worse

Feb 12, 1902 Patient returned with the statement that his sight was failing R V. with glass=10/200. L V with glass=8/200 Pupils moderately contracted T+ Fields of left contracted, as shown in Figure 11

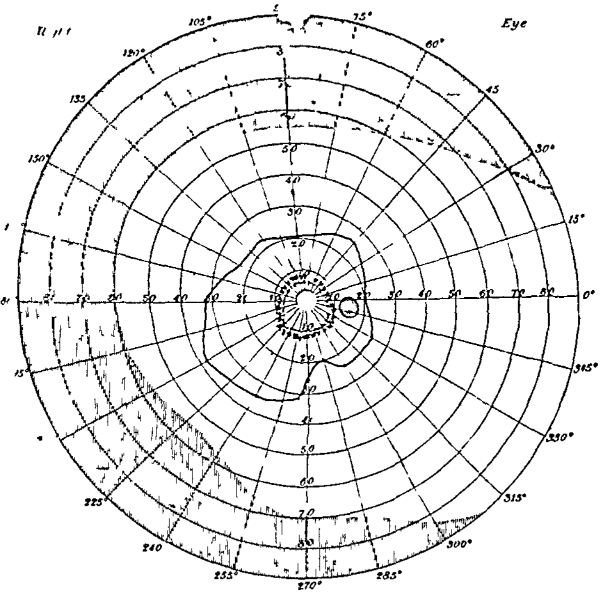

Figure 12, Case 4 —Christian K, aged 74 Simple glaucoma Oct 7, 1902 Rt eye V=20/70 T+ Obj 1 cm sq

Feb 14, 1902 Broad iridectomy upward in left eye The eye made a good recovery from the operation

Feb 24, 1902 R V with glass=15/200, T n L V with glass=6/200 T— Patient is somewhat hoarse and has imperfect power of the left shoulder He left Chicago for his home in southern Illinois He continued the use of pilocarpin, grs. ii-ʒi

A letter from him written April 10, 1903, tells me that he has R V. with glass=13/200 L V. with glass=9/200. The left vision, however, seems to be somewhat brighter than the right He says the fields are limited upward and downward, but fairly good to the temporal side. The tension in each eye is plus, that of the right being a little higher than the left

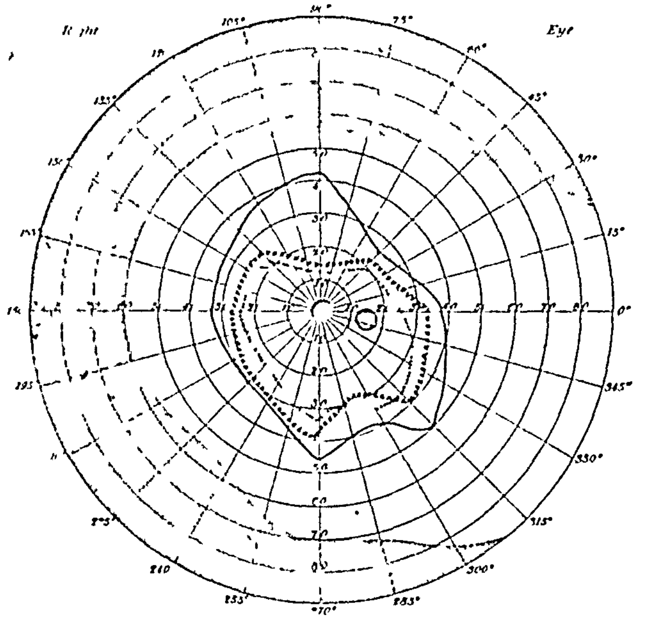

Figure 13 Case 4 —After 1 week of eserin Simple glaucoma Oct 15 1902 Rt eye V= 20/40 T n Obj 1 cm sq

He says he never has the least pain or trouble in any way in the eyes and his condition is such that he "can get around with comparative comfort," and attend to his duties as postmaster, a position he obtained after giving up his practice. His voice is hoarse and weak, and his neck in front of the scar is sensitive

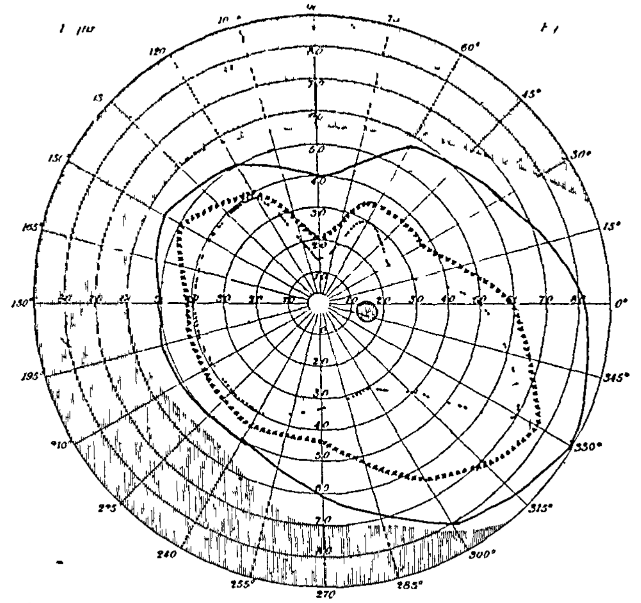

Figure 14 Case 4 —Two weeks after sympathectomy Simple glaucoma Nov 5, 1902 Rt eye V=20/40 T n Obj 1 cm sq

CASE 4 —Right, simple glaucoma Left, absolute glaucoma Right, sympathectomy (improvement)

Christian K, aged 74, admitted to Illinois Eye and Ear Infirmary Oct 3, 1902 One year before, he had severe pain in the left eye, which lasted two weeks, and which was pronounced neuralgia by one physician who saw him, and another said his impaired vision was due to a developing cataract

Halos were noticed around a light and the eye was considerably reddened. The sight was very imperfect after this period of painfulness, but the eye quieted down. Eight months later he had a most severe attack of pain in the left eye, which lasted two or three hours, after which he discovered that the eye was completely blind. This attack was pronounced neuralgia by the physician who saw him after it was over. Soon after this experience he noticed a fogginess of the vision of the right eye, more marked at times than at others. Halos were occasionally seen around lights, but he had very little or no pain in the eye. He is a strong, healthy man with no history of previous disease. Urine normal.

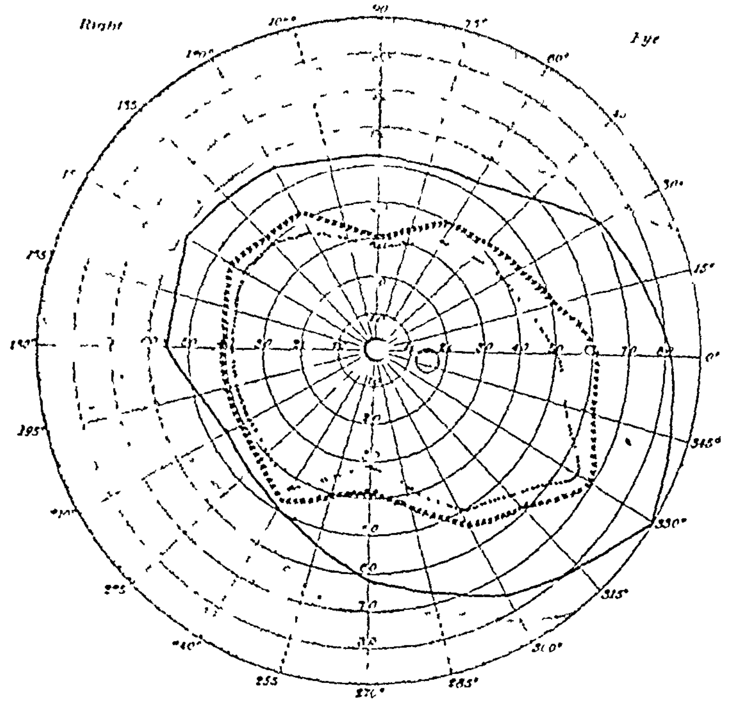

Figure 15, Case 4.—Eight weeks after sympathectomy. Simple glaucoma Dec. 17, 1902. Rt. eye V=20/40+2. T. n Obj 1 cm. sq.

On admission R. V.=20/70. Emmetropia. L. V.=0. Right eye T.+(?). A. c. of normal depth, pupil not dilated, and responds to light and acc. Optic disc not markedly cupped, but of a grayish unhealthy appearance with indistinct margin, such as is seen in incipient glaucoma.

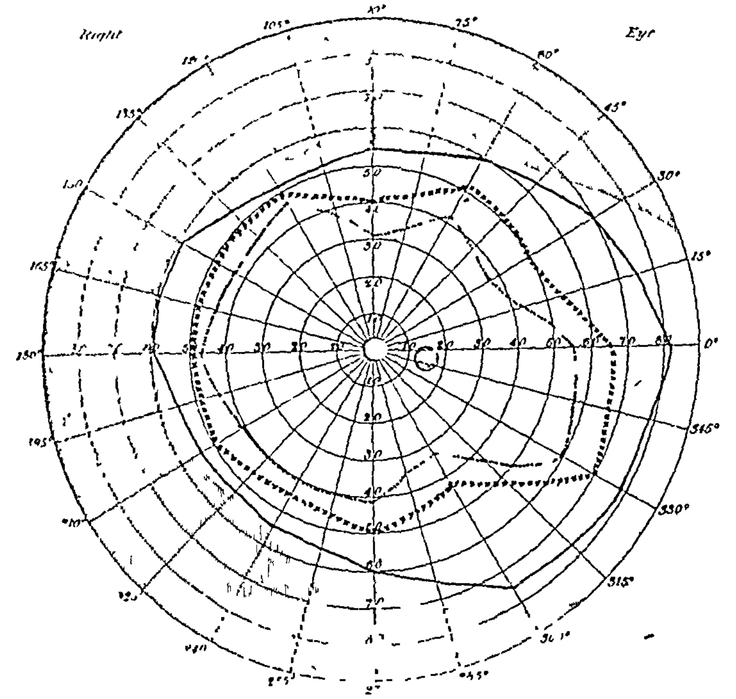

Figure 16, Case 4.—Six months after sympathectomy. Simple glaucoma. April 20, 1903. Rt. eye V=20/40+. T. n. Obj. 1 cm. sq.

Left eye, T.+3. Marked pericorneal injection. Pupil moderately dilated and shows a greenish reflex. Fundus invisible. Diagnosis: right, simple glaucoma; left, absolute glaucoma.

Eserin, grain i-ʒi, twice daily for each eye. The first chart of visual fields taken a few days after his admission is seen in Figure 12. This was not taken by myself, and may be somewhat inaccurate, for the next field, Figure 13, taken on Oct. 15, 1902, after several days' use of eserin, shows a considerably increased field; but as the central vision had improved to 20/40 from 20/70, and the tension had become normal after the use of the miotic, the improvement in the fields may probably be ascribed to the treatment. All the other fields were taken carefully by myself.

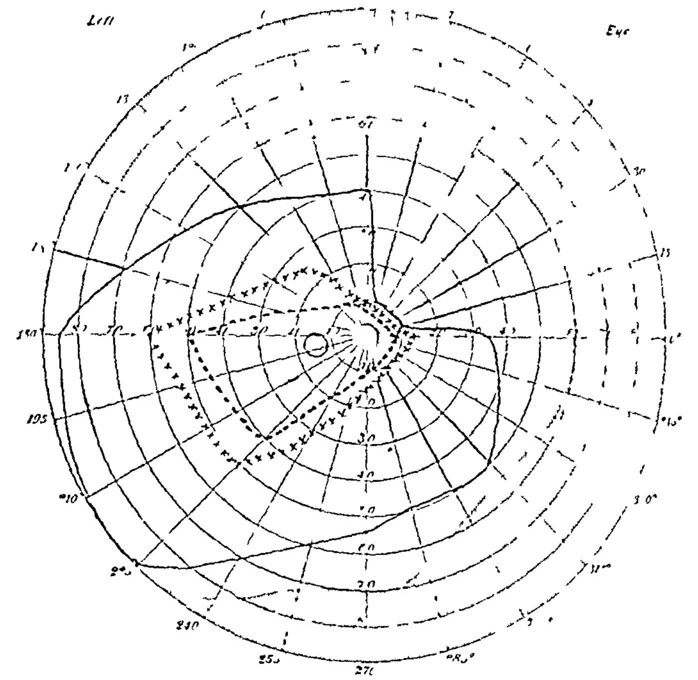

Figure 18, Case 5.—Simple Glaucoma Nov. 13, 1902 Left eye V=20/30. T.+. Obj. 1 cm sq

Oct. 20, 1902. Excision of the right superior cervical sympathetic ganglion was made by Dr. F. C. Schaefer, without any difficulty. Pupil became small immediately after the operation and tension became reduced. Ptosis followed, but there was no pain about the face or neck and no congestion of the conjunctiva or skin. Patient made an excellent recovery from the operation with no unfavorable symptoms. Slight ptosis of the right eye was noticed.

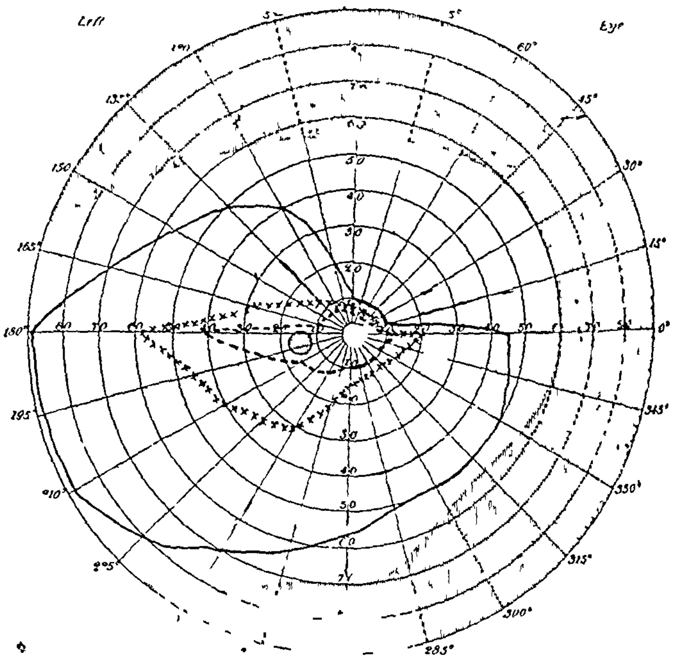

Figure 20, Case 5.—Twelve days after sympathectomy. Simple glaucoma Dec. 18, 1902 Left eye V=20/20—2 T. n Good Illum. Obj. 1 cm. sq

Oct. 28, 1902. Pupil contracted. T. n. R. V.=20/40.

Nov. 5, 1902. Fields show a remarkable improvement. (See Fig. 14.) R. V. 20/40. T. n.

Dec. 17, 1902. Improvement continues. Fields almost normal (Fig. 15). R. V.=20/40+2. Patient still has some pain in right side of face and jaw, as well as the right auricle.

Jan. 14, 1903. Left the hospital to-day. R. V.=20/40+2. T. n. Pupil contracted. Field same as above.

April 18, 1903. Readmitted. In left eye there has been severe inflammation and ulceration of the cornea, which began two or three weeks ago. R. V.=20/40+. Pupil still contracted and T. n. Fields normal (Fig. 16). It will probably be necessary to enucleate the left eye.

Case 5.—Simple glaucoma left eye. Sympathectomy. Disease stationary.

J. S., aged 76 years. First consulted me Nov. 12, 1902, complaining that for weeks previously he had the sensation of a fog being over the left eye. He had also noticed halos around a light at night. This phenomenon of colored rings he had noticed at times for years, but he remembered that at such times there was usually a slight secretion from the lids. He also experienced at times a dull pain in the left eye, and the same but less frequently in the right. He stated that at one time he had severe neuralgic pains extending from the bridge of the nose backward around the left orbit to the ear. General health good, except that he had at times indistinct rheumatic pains and suffered from a bladder disturbance, probably on account of prostatic enlargement. He wears glasses. R. Sph.+1.50 with Cyl.+1.00, Ax. 15°. L. Sph.+1.75 for distance, and R. Sph.+5.00⊃Cyl.+1.00, Ax. 15°. L. Sph.+5.00 for reading prescribed by an ophthalmologist a year or so before. R. V. =20/100 with glass, 20/30+. L. V.=25/70 with glass, 20/30. Right tension normal. Left tension slightly plus, pupil contracted with miotic, anterior chamber of normal depth, optic disc shows glaucomatous excavation, that of the right is normal. The chart of the right fields shows slightly contracted color fields. That of the left (Fig. 18) shows a scotoma in the upper nasal quadrant. Pilocarpin, grs. ii-ʒi, t. i. d., was ordered.

Dec. 1, 1902. Tension has remained about the same as before under the use of pilocarpin. Pupil remains small and anterior chamber of good depth. L. V. with glass=20/30. Left fields show somewhat more contraction in the upper nasal quadrant.

Dec. 2, 1902. At a consultation with Dr. Hotz it was decided to advise an operation. As the anterior chamber was of normal depth, and the fields have not improved under the continued use of a miotic, although the pupil was markedly contracted, it was thought that sympathectomy offered as good a chance of checking the glaucoma as iridectomy. The subject was thoroughly discussed with the patient and his family, and it was finally decided to try first the operation on the neck.

Dec. 6, 1902. Under chloroform narcosis the left superior cervical sympathetic ganglion was excised by Dr. Schaefer in the usual manner. The pupil, which for the last few days had recovered from the influence of the miotic, contracted promptly after the removal of the ganglion. There were no accidents or difficulties accompanying the operation and the patient recovered well from the anesthetic. He had complete aphonia, and marked hoarseness continued for more than a week. There was suffusion of the left eye and some congestion of the conjunctiva, mucous membrane of the left side of the nose and skin of left side of the face lasting for a couple of days. Ptosis of the left side was also noted. The patient was also confused mentally and at times had mild hallucinations and did not remember where he was. This rather alarming symptom continued for about one week, and gradually disappeared. There was tenderness about the angle of the jaw and some pain in masticating. Tension remained normal without miotic. Wound healed by first intention.

Dec. 18, 1902. Hoarseness has disappeared. Ptosis. General condition good. L. V. with glass=20/20—2. T. n. Field not markedly changed except that it seemed slightly increased in the upper nasal quadrant for white, and slightly decreased for green in the lower temporal area (Fig. 20).

The patient went to his home in an adjoining state soon after this date, with instructions to use pilocarpin regularly.

Jan. 21, 1903. Reported to me again on this date. Refraction has changed somewhat, for now he sees best with Sph.+1.25 Cyl.+0.50, 180°, which gives him L. V.=20/30. Pupil small. Tension slightly plus. Field was taken in a poor light as compared with the others, and shows more contraction, especially for colors, and a notch appears in the upper temporal field (Fig. 21). He still has some pain at corner of left jaw when he eats. Slight ptosis.

Case 6.—Simple glaucoma, left. Absolute glaucoma, right. Sympathectomy, left (improvement).

Margaret T., aged 78, entered the service of Dr. Beard in Illinois Eye and Ear Infirmary Jan. 25, 1903, and was kindly referred to me. Strong, well-preserved woman, who has usually had good health, except that since childhood she has had frequent attacks of sick headache, which continued up to two years ago, when the sight of her right eye began to fail, followed soon after by failing vision of the left. Early in the course of the disease she noticed halos around a light. On admission, R. V.=perception of light in temporal field. T.+. A. c. of normal depth, pupil slightly dilated, spicules of opacity in the periphery of the lens. Optic disc sharply cupped, with atrophy and glaucomatous halo. L. V.=8/200 with Sph.+3.50, slight improvement. T.+. A. c. of normal depth, pupil slightly dilated, faint spicules of opacity in periphery of lens; well marked, but rather shallow excavation of optic disc with halo. Retinal veins somewhat engorged. Disc rather pale. No pulsation of arteries or veins. Patient is hyperopic and has been wearing Sph.+3.25 for distance. She has marked arteriosclerosis, the superficial arteries being very hard. Urinalysis shows specific gravity 1024 albumin and no casts. The visual fields of the left eye (Fig. 22) are markedly contracted, especially the color fields, and the nasal side is almost obliterated. Fields of right eye could not be charted. Under eserin and pilocarpin the tension was reduced to nearly normal and the pupils contracted.

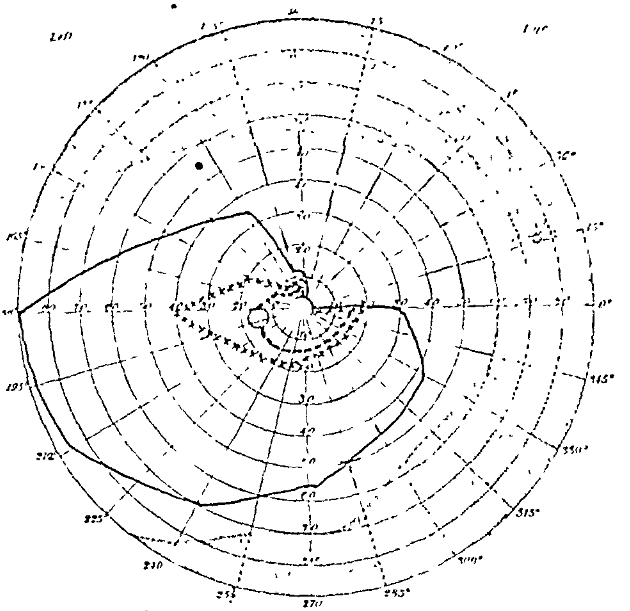

Figure 21, Case 5.—Six weeks after sympathectomy. Simple glaucoma. Jan. 21, 1903. Left eye V=20/30. T.+(?). Poor illum. Obj. 1 cm. sq.

Feb. 14, 1903. Left pupil considerably dilated 5 mm. T.+.

Feb. 16, 1903. Excision of left superior cervical sympathetic ganglion by Dr. A. E. Halstead under morphia and chloroform narcosis. The operation was uneventful and immediately after the removal of the ganglion the left pupil contracted.

Feb. 17, 1903. T. n., slight ptosis left, pupil contracted. Has headache and is hoarse.

Feb. 19, 1903. Pupil again somewhat dilated, but not so much as before the operation. It was suspected that two days before the operation some atropin had been put into the eye accidentally by the use of an atropin dropper when the eserin was being instilled and that this accounted for the sudden mydriasis. Immediately after the *operation the pupil contracted* for 24 hours, then dilated for a few days, and then again contracted and remained so. Headache persists and there is anesthesia of the left auricle.

Feb. 26, 1903. Ptosis of left. Pupil ½ mm. smaller than the right. T. n. L. V.=13/200.

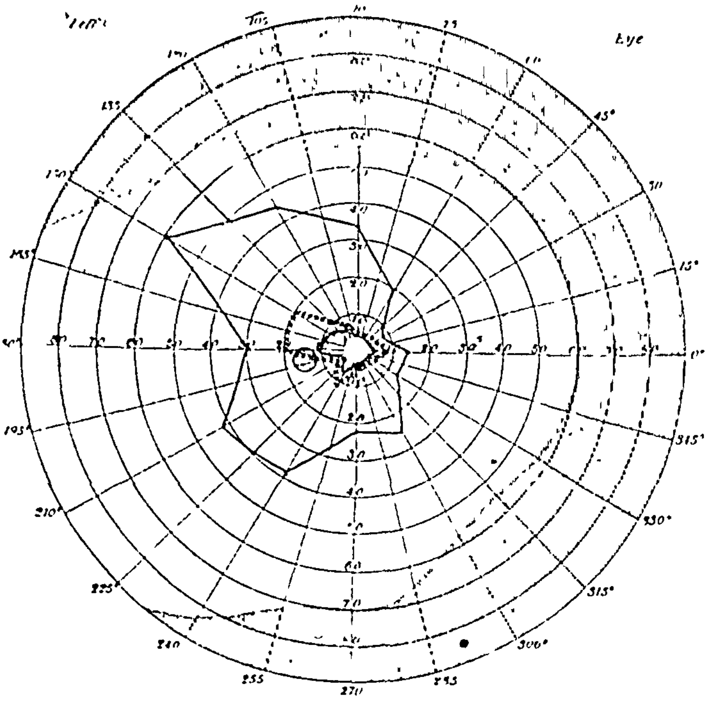

Figure 22, Case 6.—Margaret T., aged 78. Before sympathectomy. Simple glaucoma. Jan. 30, 1903. Left eye V=8/200. T.+. Obj. 1 cm. sq.

March 10, 1903. L. V.=13/200 with Sph.+3.50=20/200. T. n. Pupil remains smaller than right. Hoarseness and headache have disappeared and sensation has returned to left ear.

March 30, 1903. L. V.=18/200 with Sph.+3.50=20/120. T. n. Right pupil 3½ mm., left pupil 3 mm. Ptosis persists. Fields improved (Fig. 23).

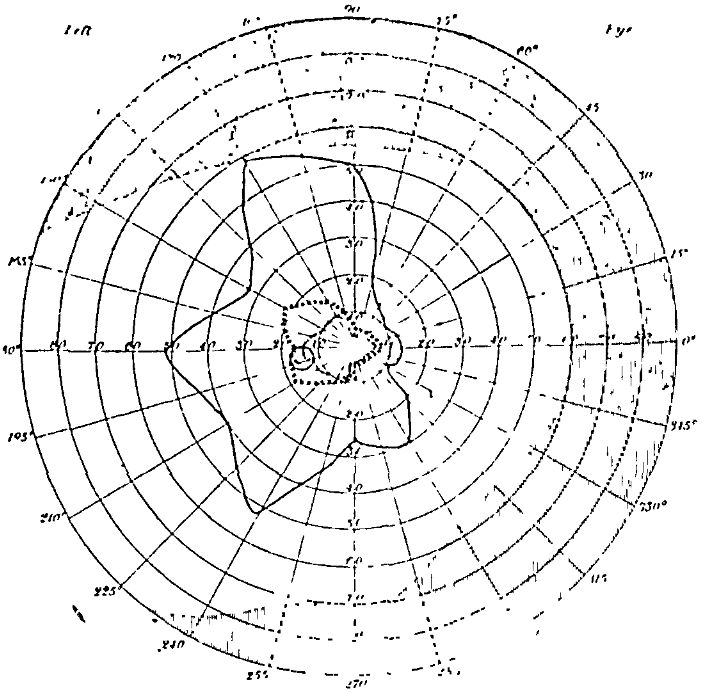

Figure 23, Case 6.—Six weeks after sympathectomy. Simple glaucoma. March 30, 1903. Left eye V=20/200. T. n. Obj. 1 cm. sq.

April 15, 1903. Left hospital with instructions to use pilocarpin and to return at once if vision begins to fail.

June 1, 1903. Readmitted to hospital. L. V. with Sph. +3.50=20/200. T. n. Left pupil smaller than right. Fields about the same as in Figure 23.

CASE 7.—Simple glaucoma, left; simple absolute glaucoma, right. Left sympathectomy (without benefit). Left iridectomy, complicated with intraocular hemorrhage. *Loss of sight.*

Chas. F. D., aged 57, was admitted to the Illinois Eye and Ear Infirmary Feb. 10, 1903, where he was assigned to the service of Dr. Chas. H. Beard, who kindly transferred him to my service. Patient usually had good health and excellent sight until two years before, when he first noticed that the vision of the right eye was foggy at times, and he would see halos around a light. The right vision continued to fail, but he had no pain or inflammation in it. Three months before his admission the same trouble began in his left eye, so that he could no longer see well to do the fine work that his occupation, that of bronze sculpture work, required. Three weeks before entrance to the hospital he first noticed halos about a light with the left eye. He states that he has had occasional attacks of temporary blindness in both eyes, lasting a few minutes. Urine normal. Arterial tension rather high. R. V. perception of light. T.+. No fields. Media somewhat *hazy.* Optic disc deeply cupped. L. V.=20/100 with Sph.+1.50=20/40, pupil responsive to light and moderately dilated, a. c.

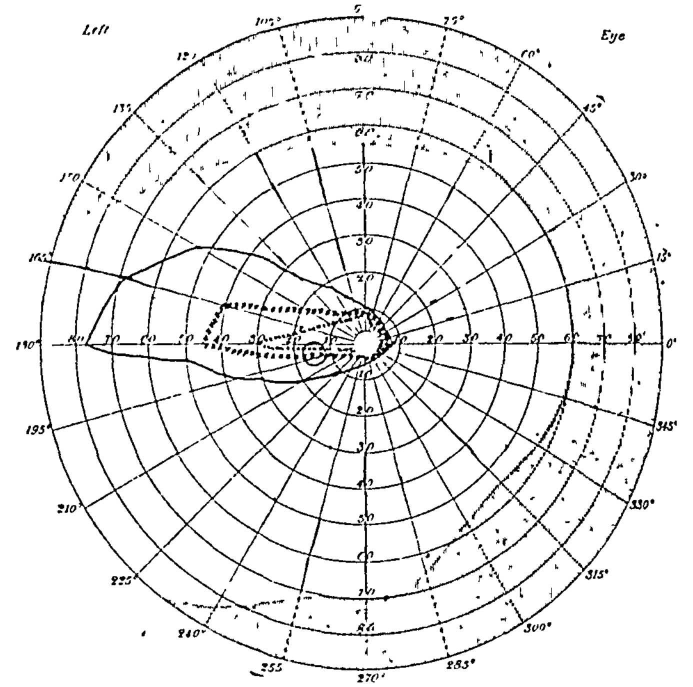

Figure 24, Case 7.—Chas. D., aged 57. Before sympathectomy. Simple glaucoma. Feb. 10, 1903. Left eye V=20/40. T.+ Obj. 1 cm. sq.

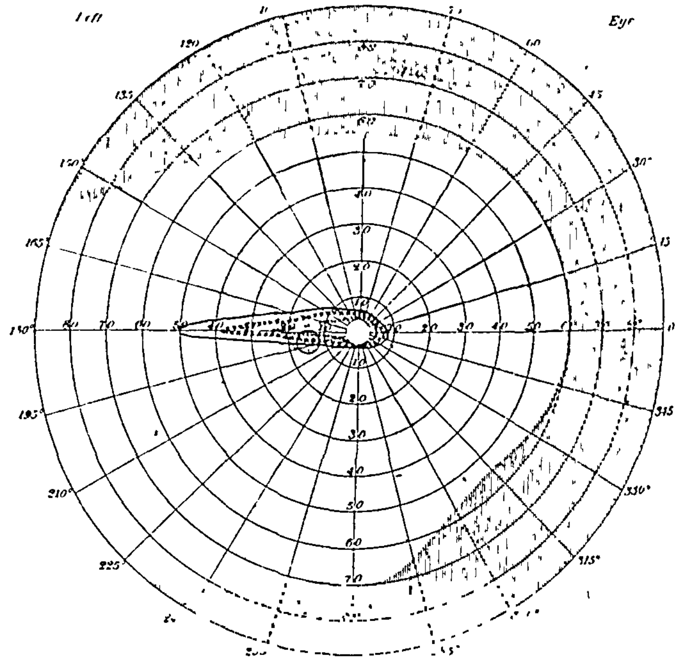

Figure 25, Case 7.—One month after sympathectomy. Simple glaucoma. March 13, 1903. Left eye V=20/40. T.+1. Obj. 1 cm. sq.

normal in depth. T.+. Glaucomatous excavation of optic disc. Fields markedly contracted, only a small temporal field remaining (Fig. 24).

Feb. 16, 1903. Removal of left superior cervical sympathetic ganglion under morphia-chloroform narcosis by Dr. A. E. Halstead. The operation was somewhat difficult on account of the patient's thick neck. The ganglion was very small, but was removed with about 3 cm. of the nerve. Spinal accessory nerve was cut and was afterward united with catgut suture.

Feb. 17, 1903. Patient recovered well from the operation. Pupil is contracted, ptosis marked. Partial anesthesia of left side of face and neck. T.+ as before.

Feb. 26, 1903. L. upper lid droops about 2 mm. more than right. Right pupil 4 mm. L. pupil 2½ mm. L.V. with Sph.+1.50=20/40. T.+. Pain in left side of face and jaw, slight hoarseness and some loss of power in left shoulder. The hyperesthesia of the left side of the face about the jaw and ear was intense, so that he could not bear the slightest touch. Eserin was used regularly.

March 13, 1903. L.V. with Sph.+1.50=20/40. T.+1. Ptosis and miosis persist. Hyperesthesia of the face gradually getting less. Fields much contracted, being reduced to a narrow slit (Fig. 25).

March 17, 1903. Anterior sclerotomy. Slight reduction of tension.

March 21, 1903. Tension again as high as before. Under cocain and holocain anesthesia an iridectomy was done upward. Immediately after completing the corneal incision the wound gaped widely and after a portion of the iris had been excised vitreous began to present in the wound and the patient complained of intolerable pain. After cutting off the portion of extruding vitreous the lens was forced into the wound and had to be removed. Then followed more vitreous and a copious hemorrhage, the patient all the time experiencing great suffering. The bleeding was finally checked and the eye bandaged. The patient was given an opiate and put to bed, and immediately had a severe chill.

March 22, 1903. Patient was fairly well and not suffering much. In the gaping corneal wound was seen a clot of blood and a tissue resembling iris or choroid. There was comparatively little reaction after the operation. The wound became smooth by the separation of the protruding mass and the blood in the anterior chamber was absorbed. At the present time, April 20, 1903, the wound has healed. Eye sensitive to touch. T.—2. V.=0. Sensitiveness of the side of the face has disappeared and the patient has completely regained the power of the arm and shoulder.

The excised ganglia in the last four cases were prepared by Dr. E. V. L. Brown, the pathologist of the Illinois Eye and Ear Infirmary, and were examined by him and also by Dr. Sydney Kuh, professor of diseases of the nervous system at the Post-Graduate Medical School. To these gentlemen I am indebted for the notes on the histologic appearances of the specimens. All the specimens were hardened in 5 per cent. formalin and corrosive acetic solution and stained with toluidin blue and with hematoxylin and eosin.

In all of the specimens there was increased pigmentation of the ganglion cells. In Cases 4 and 5, mast cells were seen. In Cases 4, 5 and 7 it was noted that the cells were not round, but of irregular shapes.

In one case, No. 6, cells slightly vacuolated were observed. In two cases, Nos. 4 and 5, it was noted that the cells showed excentric nuclei, and in the same cases marked vascularity was present. The histologic examination lacks completeness, as, unfortunately, there was not available for control study normal ganglia from individuals of the same age as the patients. As the pigment in the ganglion cells is normally increased in advancing age, it can not be said that these present an abnormality.

(*To be continued.*)

# SOME HISTOLOGIC FACTS THAT CONTRADICT THE GENERALLY ACCEPTED ODONTOBLAST THEORY.*

MICHAEL MORGENSTERN, D.D.S.

STRASSBURG, GERMANY.

While I feel very much honored by your kind invitation, I nevertheless approach my task with some trepidation, because my histologic examinations lead me to conclusions that are considerably at variance with those of others who have worked along similar lines in past years. In Germany, I have for the present only a small number of followers, and I fear that the majority of you who are assembled here to-day are also fanatic adherents of the old odontoblast theory; consequently, I assure you that I expect only a moderate amount of applause and approbation at your hands.

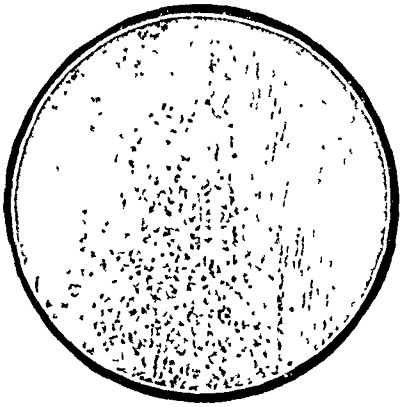

Figure 1.

But it is in your country precisely that the first voices were raised years ago against the prevailing views in regard to the rôle of the odontoblasts, and while I do not fully share the views of Heizmann, Boedecker, Abbot and Andrews, I nevertheless recognize in these men brave pioneers, and their example inspires me with the courage to appear with my results before an audience that is composed of the greatest investigators in our particular field of research.

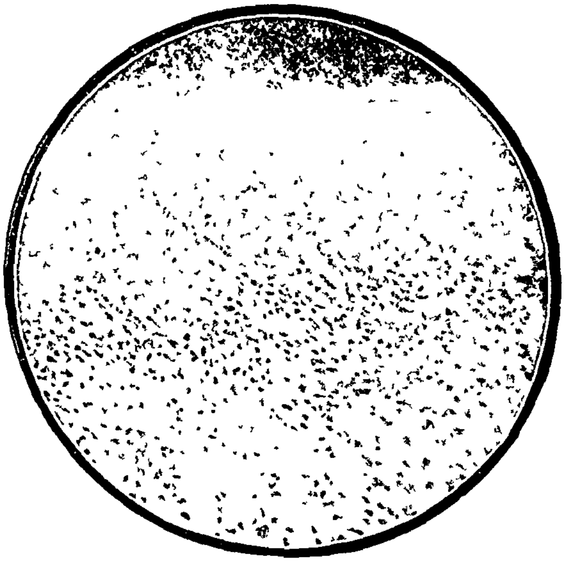

Figure 2

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

According to the views that are prevalent in regard to the rôle of the odontoblasts, the surface of the pulp is covered with a single layer of cells that are in intimate contact with each other as are epithelial cells. These are the dentin cells or odontoblasts. Each one of these cells sends a protoplasmic process (dentin fiber) into the dentin. It is claimed that these odontoblasts are perennial, i. e., that they persist during the formation of the dentin, and are neither reduced in number during this process nor replaced by other cells. It is further claimed that the nutrition and the sensation of the dentin is exclusively bound to these dentin cells and their protoplasmic processes. All subsequent formative changes in the dentin, as, for instance, the genesis of the transparent zone in caries and the broadening of Neumann's sheath in senile teeth are also believed to be exclusively due to metaplastic activity going on in the protoplasmic processes of the odontoblasts.

The great advantage of this theory is its simplicity, for the most complicated physiologic processes can be explained on a very simple, one might almost say unitarian histologic basis. The very fact, however, that everything seems so simple should lead us to be skeptical. Recent investigations into the structure and the composition of the albumins teach us that things that appear exceedingly simple are nevertheless most complicated, and it seems hardly probable that different physiologic processes can be explained on the basis of one histologic unit. True, the adherents of the odontoblast theory point out that in lower orders of animal creation a single cell or group of cells may occasionally assume all the functions of the organism and that similar conditions might obtain in the case of the odontoblasts; against this argument we can formulate the objection that the odontoblasts are simply parts of a more complicated organism, and that in higher orders of animal creation the anatomic differentiation proceeds *pari passu* with the physiologic division of labor that becomes operative in complicated organisms. One might further object that in no vertebrate is any other cell variety known to exist whose protoplasm can at the same time perform the functions of nutrition, of sensation and of metaplastic transformation.

These theoretic objections alone do not, however, lead me to doubt the correctness and the validity of the odontoblast theory as it is accepted to-day; I have, moreover, been able to discover a number of histologic facts that can not be reconciled with this theory. It is the main object of this address to demonstrate these histologic facts to you with the aid of illustrations that I have made from my microscopic preparations.

I have frequently seen in the so-called pulp horns of the dentin germ in the fetus and the new born that the dentin cells were arranged in a multiple layer. Figure 1 is one of a series of sagittal sections through the anterior dental germs of a new-born child. You will notice that each dentin cell is pear shaped; you will also notice the direction of each dentin fiber and of the capillaries, for all these features show that we are actually dealing with a longitudinal section and not with a diagonal section in which the multiple arrangement of the cells might be simulated. The layer I am discussing consists of ten to twenty rows of cells. The individual cells show no trace of lateral flattening from mutual pressure; on the contrary, capillaries and fibrillæ will be seen running between the different cells in a direction that is parallel to the longitudinal axis of the dental germ. It is clear, therefore, that the cells are not arranged in several layers on account of crowding or lack of room and mutual pressure.

The structural changes in the dentin cells also call for discussion. It will be seen that the cells become paler from the bottom toward the surface of the layer; that the nuclei disappear and that the cell boundaries become indistinct, until finally near the margin of the dentin hardly any cell remnants can be seen; for in this zone the changes in the substance and the structure of the cells are so far advanced that the dentin cells have become fully disintegrated and have disappeared from view.

If with Figure 1 we compare Figure 2 that is made from a frontal section through the pulp ridge of a young calf tooth. we will find the same conditions. Here, again, we see a broad layer of oval and round cells that are already beginning to become pale, extending up to the edge of the dentin. The layer here consists of some twelve rows of cells. These cells are odontoblasts in a state of dentinogenous metamorphosis, and show evidence of beginning disintegration. Between the cells we see capillaries running in the same direction as the dentin canaliculi. Below this zone we see the pulp cells in close aggregation, arranged in rows and extending their processes into the layer of disintegrating odontoblasts. These cells are in a state of conjugation and lead by that the formation of odontoblasts.

In preparing a tooth germ according to the method of Koch-Weil and in making a section without decalcification, spherical solid structures are seen in place of the pale disintegrated odontoblasts. These spheres were formerly considered to be dentin spheres or globular masses, and were described by these names. In another stage of the formation of dentin a transparent, homogeneous layer composed of single trabeculæ is occasionally seen in place of the disintegrating odontoblasts.

If a tooth that is still in a developmental stage is only incompletely decalcified, spherical structures are also seen in the place of disintegrating odontoblasts. Many of these little globules, however, contain remnants of cells and nuclei; in injected specimens I was even able to detect capillaries between the spheres. These capillaries could be sharply differentiated from the colorless spheres of dentinogen by their intense color.

After this discursion you will be able to understand Figure 3, which is prepared from a frontal longitudinal section through the germ of a molar tooth in a new-born infant. The preparation was decalcified until all the calcium salts were removed. In the natural state dentinogenous masses of spheres were found throughout the whole visible portion of the pulp. After careful and thorough decalcification, a wide layer of disintegrating cells was seen instead, in which odontoblasts could no longer be found. Toward the center, pulp cells are seen that are odontoblasts, and that send processes or fibrillæ into certain portions of the area of disintegrating cells and through this zone into the dentin.

In a later stage of formation dentin appears in the place of the mass of globules, and the pulp cells are seen to have undergone metamorphosis into trabeculæ of odontoblasts. Some of them become distended and appear as cartilage cells that are surrounded by a light areola. This is the stage that preceded the disintegration or the dentinogenous formation of globules and that is illustrated in Figure 4. This specimen is prepared from a longitudinal section through the dentin germ of a sheep's fetus.

As long as the formation of dentin continues, the arrangement of dentin cells in multiple layers can be demonstrated. In a preparation from the longitudinal section through a normal bicuspid in a girl of 12 years, the layer of odontoblasts still consists, at some places, of seven to eight rows of cells. I have been able to show in innumerable sections that the odontoblasts that are arranged in several rows underneath each other are not merely different layers of a single row that have become displaced so as to lie below one another, but really consist of several rows of cells.

I have been able to demonstrate this conjugation of pulp cells for the purpose of odontoblast formation in the earliest developmental stages. In Figure 5, made from the tooth germ of a human fetus, the genesis of the small number of odontoblasts that is formed in this specimen from confluence or conjugation of pulp cell (mesoblasts) can be clearly seen. In those places in which no odontoblasts have been formed, single fibrillæ, i. e., preformed dentin fibers, appear underneath the layer of enamel cells at the margin of the dentin germ.

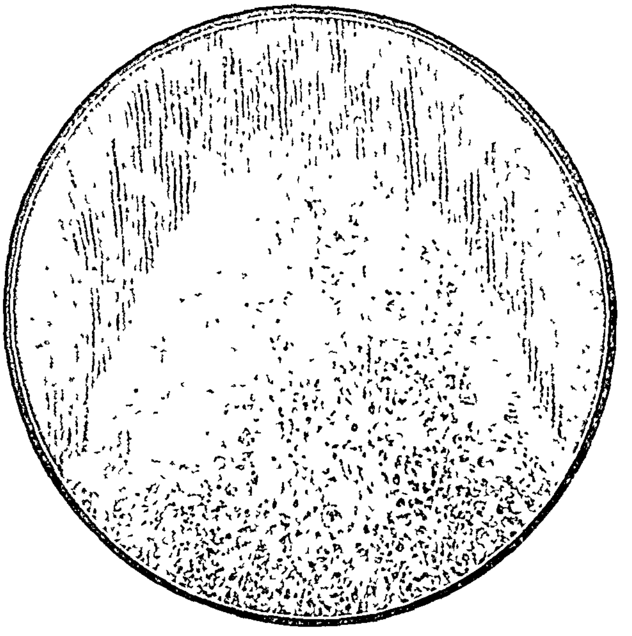

Figure 3

In a somewhat later stage and after dentin has already been formed, odontoblasts arranged in trabeculæ appear. Many of these later odontoblasts, however (as shown in Fig. 6), no longer possess a nucleus, whereas the odontoblasts in Figure 5 may even possess two or three nuclei.

I believe that I have adduced valid arguments against the existing odontoblasts theory by the demonstration of these illustrations (Figs. 1 to 6), for I have been able to show (1) that, at least in the earliest developmental stages of the teeth an odontoblast originates from several cell units; (2) that during the different periods of tooth formation a multiple layer of odontoblast cells can be demonstrated; (3) that, finally, the external rows of this layer undergo metaplastic transformation so that they disintegrate. Consequently I argue that it is impossible for each odontoblast to persist throughout the whole period of tooth formation without being destroyed and subsequently replaced by other cells from which the dentin is ultimately formed.

The innumerable smaller cells that are seen underneath the layer of odontoblasts have been completely ignored by the adherents of odontoblast theory. The fact, moreover, that the nuclei of the odontoblasts show no karyokinetic figures has been misinterpreted by them. The replacement of the odontoblasts that are destroyed in process of dentin formation does not occur by cell regeneration and karyokinesis of nuclei, but by proliferation of the small underlying pulp cells that are connected by innumerable protoplasmic anastomoses with the dentin cells.

The salient feature of this whole investigation is to show that dentin cells are actually used up in the process of dentin formation. If it should be possible to demonstrate the presence of transition forms between the different forms of cells that are in process of metaplastic metamorphosis this postulate would be fulfilled. When the formation of dentin proceeds quietly and uniformly, such transition forms are not easy to find when the formation of dentin, however, proceeds in an irregular manner, i. e., when "functional irritants influence the formation of dentin," then it is an easy matter to find such forms of cells. I take the liberty of demonstrating by the following illustrations what I wish to show. The specimens are taken from the roots of teeth from ruminants, rodents and fish. I have already in a separate monograph described the results of these particular investigations on the formation of dentin in these species.

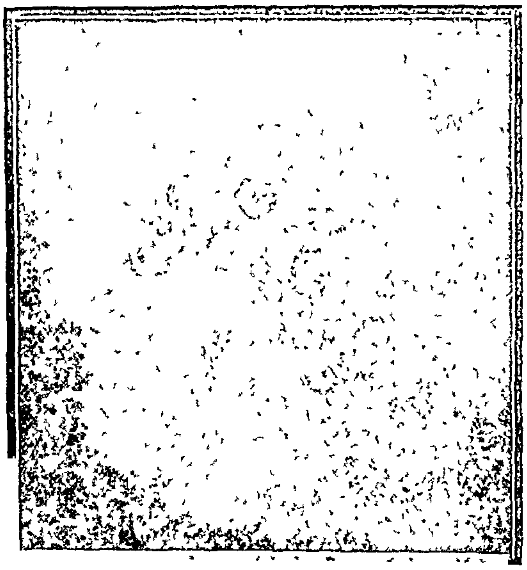

Figure 4

Figures 7 and 8 are made from cross sections through the root of a cow's tooth in its first stage of development. We see a narrow strip of dentin with fenestrations; within the openings of the dentin are seen odontoblasts, some of them still connected with one another by protoplasmic processes. The substance of the majority of the cells is changed, and owing to "dentinogenous transformation" that is taking place, they appear black. In the narrow odontoblast layer we see pale odontoblasts, and in addition some cells that are colored black. In this layer, therefore, we see the same change in the substance of the cells throughout.

In Figure 8 the layer of odontoblasts is irregular, somewhat broader than above and interrupted in many places by protruding plugs of dentin. The odontoblasts of this layer correspond in regard to arrangement, form and substance to those that are found in the interior of the dentin.

The gradual transition of pulp cells into the layer of odontoblasts, as well as the transition of the odontoblasts into particles of dentin, can be seen clearly in Figure 9, made from the first dentin appearing in the roots of a cow's tooth. The changes in form that the odontoblasts undergo in the process of dentin formation can be seen particularly well. In Figure 10, in which we see that the dentin is broader, the arrangement in rows, the conjugation and the changes in the substance of the odontoblasts can be seen on a somewhat larger scale. In Figure 11 the dentin contains two plugs, consisting of different kinds of cells. The other margin of these plugs is very pale and is seen to be undergoing metamorphosis to dentin.

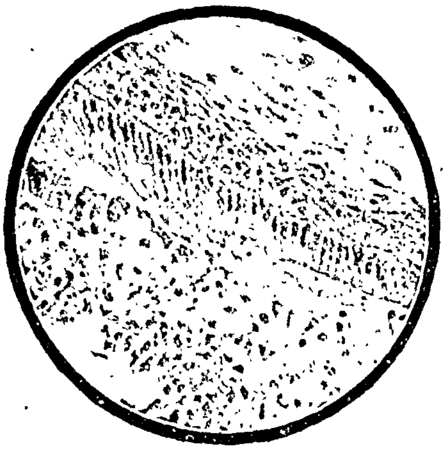

Figure 5.

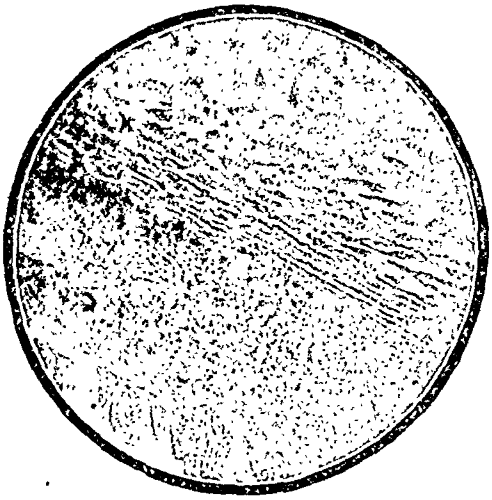

Figure 6.

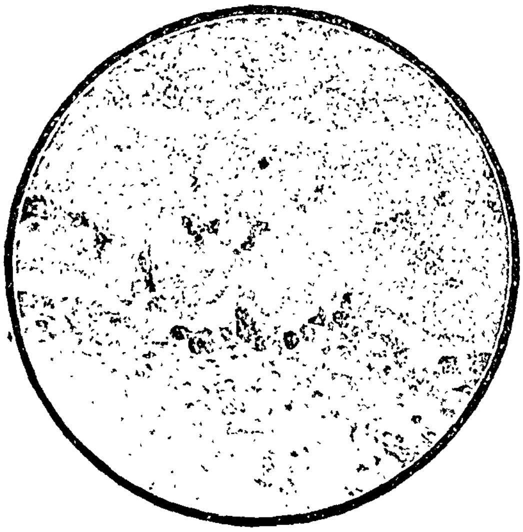

Figure 7.

These plugs that frequently pass through the layer of odontoblasts and almost penetrate to the cement layer in the dentin, may easily create the impression that dentin had been previously formed, had again been absorbed and had been subsequently replaced by pulp tissue that had penetrated into the spaces created in this way. This view, however, is opposed by very valid arguments. I have studied the peculiar formation under discussion through all developmental stages, i. e., from the very beginning of tooth formation to the completion of root growth, and I could determine on the basis of thousands of observations that these plugs never penetrate into finished dentin, but are only found before the formation of dentin is complete. The plugs represent masses of pulp that remain behind in certain areas, owing to an irregular development of the dentin. Later these plugs are destined to undergo the same metamorphosis as other portions of the pulp that are further advanced in their development. Finally these plugs disappear and the area they occupy is replaced by normal dentin.

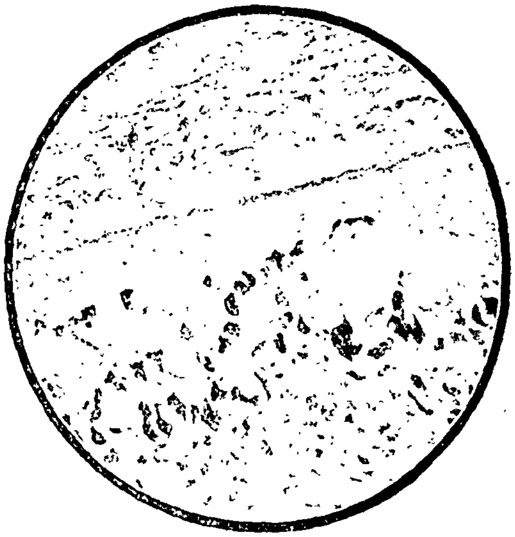

Figure 8.

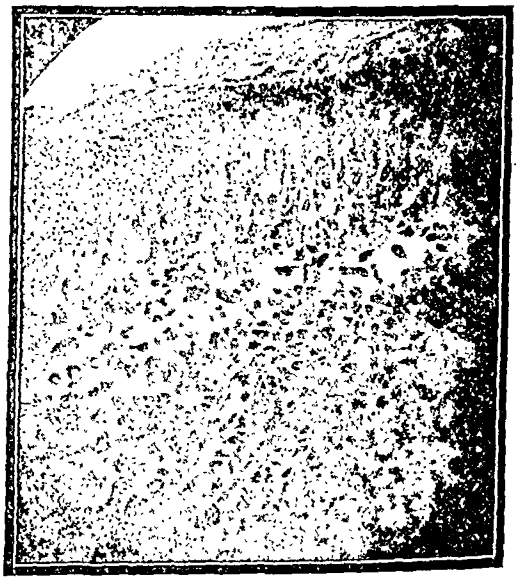

Figure 9.

Gero Rudas has recently stated that the presence of cells in the dentin is always due to the invasion of leucocytes, and that the development of the pulp is deficient in those places in which incapsulated pulp cells are found. I am forced, however, to deny the correctness of these statements from my own experience. I believe I have shown that the cells within the dentin do not consist of invading pathologic leucocytes, but of mesodermic cells and dentin cells that have been passively inclosed. Under normal conditions these cells disappear without leaving a trace. Only in those cases in which the developmental processes are arrested—as, for instance, by rapid and great destruction of the cutting edges of the teeth from overuse with resulting atrophy of the pulp—do we see deficient development of dentin in such places.

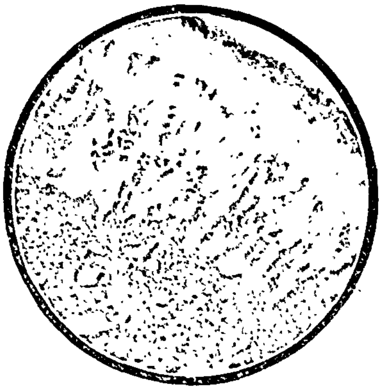

Figure 10.

In the dentin of certain animals, however, we sometimes see single cells, cell groups and cell territories that probably persist during the life of the animal; they must either persist as living cells that are normal or as decayed cell rudiments. I have been able to find such cells, particularly in the teeth of rodents and most frequently in the molar teeth of rabbits. In Figure 12 such cell territories are shown, and in Figure 13 single cells inclosed in the dentin of rabbits. We know nothing positive in regard to the significance of those cells.

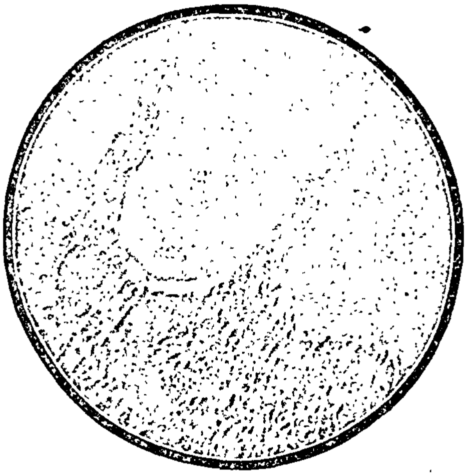

Figure 11.

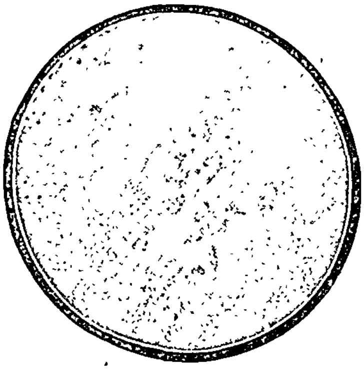

Figure 12.

What we learn from the formation of dentin under the influence of functional irritants is that dentin may be formed without a typic layer of odontoblasts and that the pulp cells that were heretofore considered to be completely indifferent are directly concerned in this process; and finally, that the latter are arranged in rows during this developmental process without ever being transformed into typic odontoblasts. The transformation of these cells into dentin may, however, be followed step by step, for it can readily be shown that they, as well as the odontoblasts that are inclosed within the dentin, are gradually converted into dentin; and this, I argue, proves that in the formation of dentin, dentin cells are used up.

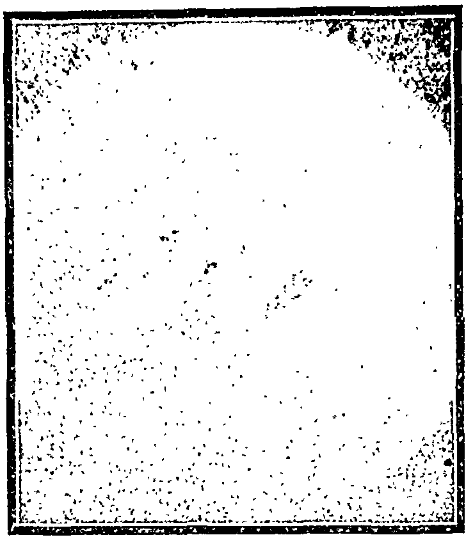

Figure 13.

At all events we may assume as positive that no conclusions can be drawn from the fact that the odontoblasts form one layer in regard to the permanence of the odontoblasts, nor in regard to the continuous disintegration of these cells and the replacement of the destroyed cells by new ones. I am inclined to the belief that the formation of a single layer of odontoblasts constitutes merely a transitory stage in the development of dentin, and a stage, moreover, that need not necessarily be observed in all cases.

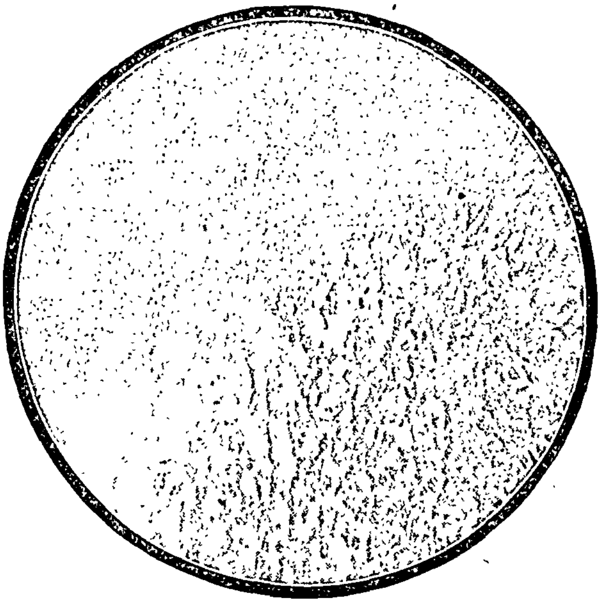

Figure 14.

In connection with the old odontoblast theory, the idea is often expressed that the perennial dentin cells (whose number always remains the same) advance toward the pulp as well as toward the dentin, and that in process of advancing toward the pulp they displace this tissue. The question is not decided, however, whether or not all the constituents of this displaced pulp undergo atrophy or whether they are merely compressed. In the light of my discovery of the metamorphosis of pulp cells into dentin cells and of the continuous degeneration of the latter, this view is altogether untenable.

Only one explanation seems satisfactory, namely, that more and more of the pulp becomes included in the process of dentin formation. must assume consequently that the pulp becomes smaller and smaller, and we do not need to postulate compression nor atrophy of the pulp to explain its gradual shrinkage.

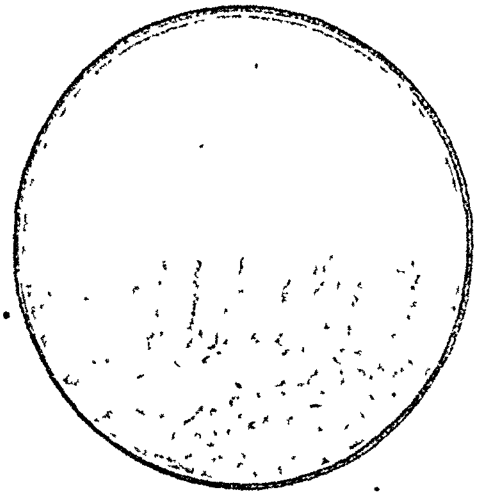

Figure 15

What becomes of the blood vessels and the nerves in those portions of the pulp that are converted into territories of dentin cells?

I attempted to solve this query many years ago, and have made it the subject of a comprehensive investigation. The main results of my studies have been described in a lecture. I found that the blood vessels either undergo atrophy or are converted into intraglobular spaces. I also showed that the nerves, with exception of the axis cylinders, are converted into a hyaline substance that later undergoes calcification and that the axis cylinders partially disappear and partially persist. At the same time I showed that these cylinders are very difficult to demonstrate histologically.

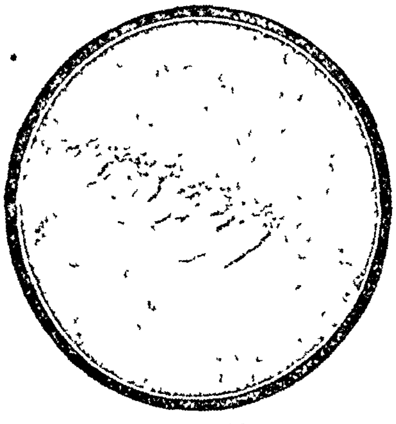

Figure 16.

One of my arguments in favor of the view that new pulp areas are constantly included in dentin formation, is that the histologic structures within and below the odontoblast layer undergo continuous changes. At one time we may see numerous capillaries between the odontoblasts, occasionally even between them and the layer of dentin; in other cases, a layer of odontoblasts will be found containing no trace of blood vessels. Sometimes the pulp immediately below the odontoblasts contains very many cells and sometimes it contains very few. Frequently a large number of very fine fibers are seen in this zone, constituting what is called Weil's layer; in other instances this layer will be found to consist of a finely granular material containing neither cells nor fibers. The vaso-dentin of fish teeth is a classical example of the continuous participation of pulp territories in dentin formation without the agency of odontoblasts. If we look at the question in this light, the dentin fibers must need assume an altogether different histogenetic relation to the odontoblasts than has hitherto been postulated. It seems impossible that the fibers should arise exclusively from the odontoblasts that are situated at the surface of the pulp, and they must also be imagined to arise in part from pulp cells situated deeper down in the pulp. In other words, they must be more or less preformed in the pulp, and can not be said to originate by metaplastic transformation as a residuum of the dentin cells in the process of dentin formation.

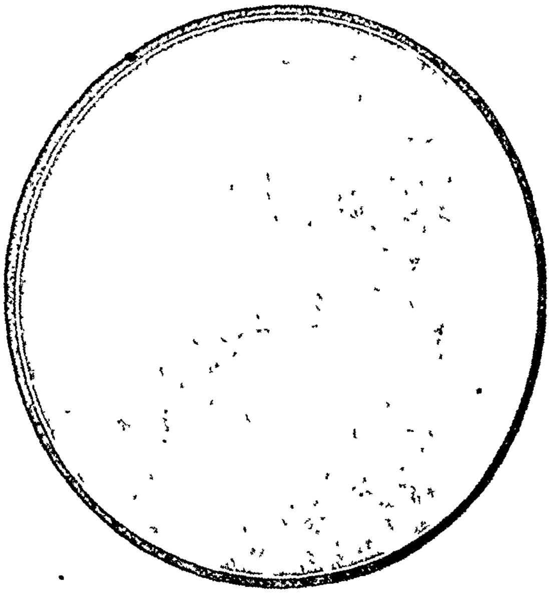

Figure 17.

The next slides demonstrate these postulated conditions. In Figure 14, made from the molar tooth of a young rabbit, a layer is seen underneath the young dentin that contains very few cells and that is traversed by fibers. Here dentinogenous disintegration of odontoblasts has taken place and the dentin fibers originate from the deeper cells.

Figure 15 is made from the tooth of a sheep fetus and under a high power shows fibers that run between the multiple layer of odontoblasts. In other words, these fibers pass through the whole layer of the odontoblast cells into the dentin.

Figure 16 is made from the pulp of a young human premolar. Fibers will be seen passing from the layer of odontoblasts deep down into the pulp; these fibers constitute the so-called layer of Weil.

Figure 17, made from the same series of cuts as Figure 16, shows a spot in Weil's layer under a higher power. Numerous fibrillæ are seen to originate from the circumference of a single capillary. These fibers enter the odontoblast layer. They are very different in appearance; most of them stain like fine connective tissue fibers; some of them are fine tubules that are occasionally found to contain a few red blood corpuscles. In most cases, however, they are so fine that blood corpuscles can not pass through. Formerly I described these tubes as lymphatic channels, but am now inclined to the belief that they are blood vessels and that they constitute very fine nutritional or tissue fluid fibers of a variety that has hitherto never been described in dental tissues. By a special method of preparation I have been enabled to demonstrate large numbers of them between the dentin cells, and could also repeatedly demonstrate their presence in dentin. These channels, that vary in thickness from one-fourth to one-third the width of a cell nucleus, usually terminate in a knob-like loop.

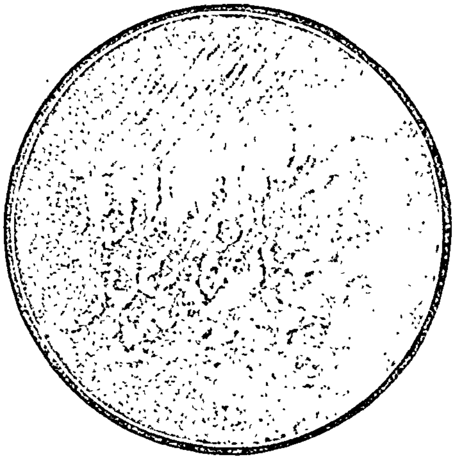

Figure 18.

I call your attention particularly to these channels and capillaries that pass between the dentin cells, for there is resemblance in regard to distribution and location between these structures and the dentin fibers. In Figures 15, 16 and 17 both structures are seen to pass side by side through the odontoblast layer and below it, i. e., in Weil's layer; but I have also been able to show repeatedly that in addition to Tomes' fibers fine channels frequently enter the dentin, the method I employed for demonstrating their presence being either injection of the specimens or special preparation of a series of cuts made from the fetus of cows, fish and sheep.

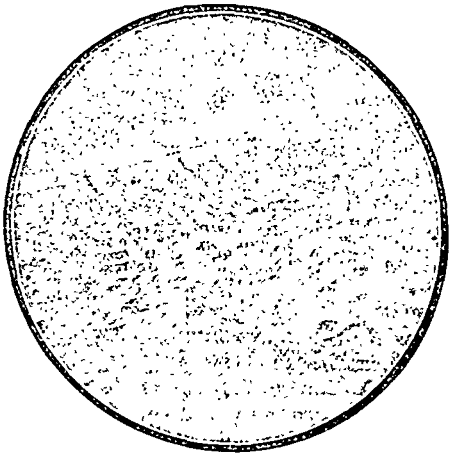

Figure 19.

The question of the nutrition of dentin can only be solved after the relation existing between Tomes' fibers and the fine channels that I have demonstrated between the odontoblasts is explained.

I believe, however, that I have definitely solved the question of the sensibility of dentin by my demonstration of the entrance of nerves into the dentin. That the sensibility of dentin is not dependent on the presence of odontoblasts in the dentin, as taught by Black, Walkoff and other authors, could be demonstrated clinically by the fact that teeth whose pulp was completely calcified and that contained no more odontoblasts were still highly sensitive. In these cases of general calcification the axis cylinders were not involved in the process and remained intact.

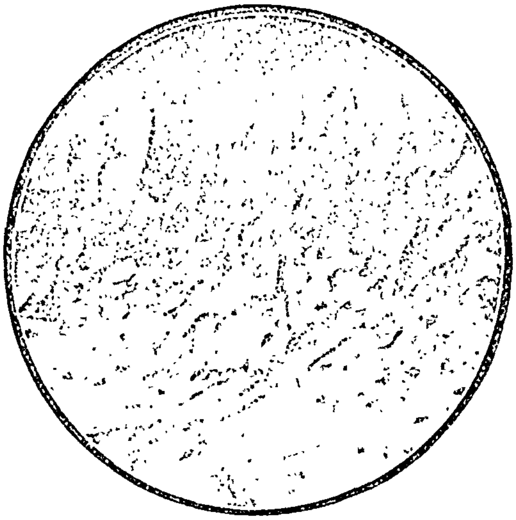

Figure 20.

Boll in 1868, Boedecker in 1883, the writer in 1892 and Römer in 1899 demonstrated the fact that pulp nerves pass into the layer of odontoblasts. The deviation of nerve fibers between the odontoblasts and the dentin was observed in 1892 by Retzius and by Huber in 1899. The entrance of nerves into the dentin I demonstrated in 1892 and Römer in 1899.

In older specimens nothing but pale fibers are seen in those places were nerves entered into the dentin. These fibers, however, are clearly differentiated from the other tissues. This may be seen in slide 25, made from an old specimen prepared from a young rabbit's tooth.

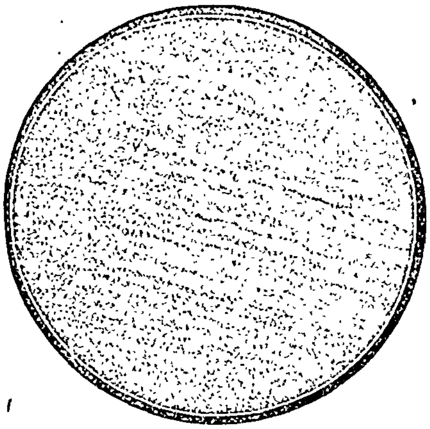

Figure 21.

In preparations made according to my modification of Mallory's stain, the axis cylinder is clearly differentiated from all other stained tissues. Preparations of this character, as will be seen from the following slides, can be preserved for a passably long time.

In Figure 18, made from the dentin germ of a sheep's fetus, a few of the axis cylinders that run toward the center of the odontoblast layer between the dentin cells can be clearly recognized. They pass from the parietal sheath or the nerves of the dentin germ and can be followed through the whole odontoblast layer beyond the boundaries of the dentin.

In Figure 19 the entrance of nerves into the dentin can be seen still more clearly. One of the axis cylinders is seen to terminate in a knob-like ending in the dentin, and another one terminate in a similar way before reaching the dentin, i. e., in the odontoblast layer.

The course of the nerves in the odontoblast layer varies greatly. They often traverse the layer in the same direction as the dentin channels and the odontoblasts. In some places they deviate from this direction. Sometimes they form a veritable plexus with all their small lateral branches. The nerve fibrils apparently originate from cells and cell nuclei. If one looks carefully it will be seen, however, that they are merely close to the cells and really pass alongside of them.

At the point of division of the nerves of the odontoblast layer I have frequently seen one or more spindle-shaped enlargements. Such places are shown in Figure 20.

In conclusion, I take the liberty of demonstrating in Figure 21 the course of the nerve fibers within the dentin channels in a cow's tooth. The preparation was made according to Golgi by the sublimate method after the specimen had previously been injected with methylene blue. The fibers of Tomes appear pale; the fibers that I call axis cylinders are darker and frequently form spirals around the dentin fibers. They are situated between the walls of the dentin channels and the fibers of Tomes.

Basing on a series of histologic facts that I have attempted to illustrate to you with the aid of a few photographic slides of some of my specimens, I believe I have demonstrated the generally accepted odontoblast theory, the theory of dentin formation and of the sensibility of the dentin are untenable. While I do not dare to substitute a new and complete theory for the old one, I hope, nevertheless, to have contributed a few new facts by my investigations that may form the basis of an odontoblast theory that will satisfy us both in an anatomic and physiologic sense.

---

# DIABETES AND OBSCURE PHYSIOLOGY.

CARL RAMUS, M.D.
Assistant Surgeon in the United States Public Health and Marine Hospital Service.
SAN FRANCISCO.

Of the many unsolved problems in pathology none perhaps possesses a greater interest to both theorist and practitioner than does the origin of diabetes mellitus. Its etiology is even yet shrouded in mystery, notwithstanding the enormous amount of study that has been devoted to it, and the situation may be summarized in the statement that of no other pathologic condition is there so much known, and yet so little. Many and various have been the theories advanced from time to time, each having a few facts apparently supporting it, but as they conflicted with each other in important particulars, one after another they were abandoned, for the advancement in physiologic chemistry made it possible more and more to explain the different and complex processes by means of which the several classes of foods passed through stage after stage of preparation and elaboration until they were fit to become incorporated into the tissues of highly organized beings. One after another the more conspicuous organs were taxed with the responsibility, and were believed to be the seat of the diabetic phenomena. But with the progress of science the theories on which these opinions had been based were discredited, and they were reluctantly given up.

The theory that will be set forth in this paper is believed to be new as concerns its application to diabetes mellitus; but it has, however, appeared previously in medical literature in relation to purely physiologic researches concerning the ultimate state of the carbohydrate foodstuffs immediately preceding their absorption into the tissues. The various known facts on which this hypothesis is erected will be cited as required, not always chronologically, but in the order in which they apply here.

The inquiry concerns physiology as well as pathology, and, if the theory is correct, is as important to one as to the other. But before making any definite statements it will be in order to review briefly the experimental and clinical knowledge of diabetes mellitus, adding thereto our own observations.

The history of the scientific study of the subject up to the present, may with propriety be divided into four periods.

The first was inaugurated by the brilliant "piqûere" experiments of Claude Bernard. The important results finally arrived at through this class of experiments were, first, that violent stimulation applied to various parts of the nervous system was generally followed by glycosuria; second, that this was the result of a sudden liberation of glycogen in excess sufficient to pass through the renal parenchyma. Here we have strong evidence to show that under some conditions the nervous elements alone may be concerned in the production of some of the diabetic phenomena. This possibility has been further strengthened, in some instances, by necropsies showing definite pathologic conditions in important nervous locations. To this class may perhaps belong the occasional instances of diabetes following severe shocks of emotional and psychic nature; also those grave cases where no morbid anatomy could be found.

The second period began with the series of experiments that demonstrated the power of certain drugs, notably phloridzin, to produce temporary glycosuria. But the glycosuria obtained from phloridzin was found to be very different from that derived from the preceding experiments on the nervous systems. According to Von Mering and others it does not appear to depend upon glycogen liberation, the blood being poor in dextrose, and the glycosuria occurring in starving animals, and even after extirpation of the liver. The dextrose here must be formed principally from the albuminous tissues, and it seems probable that the glycosuria is the result of an altered condition of the renal functional tissue, brought about by direct action of the poison itself. This opinion is held by no less an authority than Von Noorden, who suggests the possibility that in some clinical cases the glycosuria may be the result of unknown toxins analogous to phloridzin circulating in the blood and acting on the kidneys. It seems evident from these researches that there are poisons existing in Nature capable of causing diabetic symptoms through their influence on the renal functions, and therefore clinical examples of diabetes mellitus from such sources are not at all beyond the range of possibility. There is no question but that the kidneys frequently exhibit pathologic conditions in diabetes, many showing catarrhal nephritis and at times fatty infiltration. One authority states that albuminuria is present in about one-third of all cases. Of course much of such pathology is without doubt secondary, being the result of long overwork in excreting water, and irritation from the constant transit of sugar. However that may be, the results of the phloridzin tests must be considered to occupy an important place in the literature of this disease.

The third, or pancreatic, period marks the most important advance thus far made in the study of diabetes mellitus, bringing also new discoveries in physiology. Since attention began to be seriously directed to the pancreas as the organ most concerned, surprising and far-reaching facts have been brought to light. The pathologic findings in about 50 per cent. of the necropsies showed plainly that the functions of this gland were interfered with or suppressed, and these observations perhaps inspired the painstaking and conclusive experiments of Von Mering and Minkowski, and also, independently, of di Dominicis, an Italian scientist. The importance of the work of these men in this field is simply incalculable. It has demonstrated beyond all reasonable doubt that removal or total suppression of function of the pancreas is invariably followed by typical diabetes mellitus. Since such experiments in the human species are entirely out of the question, it follows that these scientists were compelled to obtain their results from careful tests made on the lower animals, dogs having been selected for the purpose. The objection might be—and has been—urged that while the results of such experiments were probably conclusive in regard to the lower animals, they would not necessarily hold good for mankind. In reply to this it is now possible to cite at least one case in man which may be considered as experimental in the diabetic sense. It is referred to by Osler as a patient of W. T. Bull who died of diabetes after extirpation of the pancreas. The previously referred to investigators further showed that the anti-diabetic property does not reside in the pancreatic juice; that a small portion of the pancreas, with its blood supply, remaining in the body prevents diabetes; that practically total extirpation of the organ is necessary in order to produce diabetes. They concluded that the action of the pancreas on the excretion of sugar is probably specific, no other organ possessing it. The latter statement is perhaps too radical in view of more recent studies of the suprarenal capsules. This paper will, it is believed, furnish evidence that will further strengthen the belief in the pancreatic origin of diabetes mellitus, possibly in all of the true cases; but no effort will be made to prove that all cases of apparent diabetes mellitus are necessarily pancreatic in origin, or can be explained by any one theory. But to return. The most significant facts shown in the pancreatic experiments were, that the pancreatic juice had no influence on the production of diabetes, and that the presence of a small portion of the pancreas prevented its occurrence. Of course the only explanation is that the pancreas acts in a manner similar to the ductless glands and that its internal secretion is of far more importance than its digestive contribution.

After consideration of the results derived from pancreatic sources it seems unreasonable to doubt that many cases of diabetes, probably the majority, have their origin in diseases of the pancreas. Lépine's experiments and theory furnish more evidence in support of the conclusions of Von Mering and Minkowski, and di Dominicis, but as it forms a strong link in the chain of evidence favoring the theory to be put forward here, its consideration will be postponed until it is taken up in proper order.

The fourth period in diabetic research may be said to have begun with Crofton's discovery of the relation thereto of the suprarenal capsules, made, I think, in 1901, The present writer regrets not having been enabled to more than glance at the important and very interesting work recently done as a result of this discovery. But the most pertinent fact demonstrated seems to have been that injection of adrenal extracts can cause glycosuria. Previous workers have shown that several chemical substances are able to induce glycosuria, but none of these have been shown, as yet, to occur naturally in human or animal bodies.

At last, however, a substance physiologically present is found to have the property of causing glycosuria when administered under certain conditions. A wide range of possibility is thus unrolled, and a new field, nearly unexplored, presents itself for investigation. Much testimony has since accumulated, confirming the first important discovery and bringing to light new facts, several of which must be referred to.

It was stated in one publication that adrenal extract had been found to have the additional property of converting starch into dextrose. Herter, in 1902, found that when a solution of adrenalin chlorid was applied to the surface of a dog's pancreas glycosuria resulted. He also found, however, that several foreign substances, known to possess power as reducing agents, were able to effect the same, while oxidizing agents had no effect whatever. Herter concluded from these experiments that adrenal secretion produced glycosuria by means of its reducing power of the pancreatic tissue. I shall have occasion to refer again to this subject.

Having enumerated the main conditions now known to bear a causative relation to diabetes mellitus, or to glycosuria, the physiologic aspect of the matter must receive attention. For the purposes of this paper, the carbohydrate group of foodstuffs is the one mainly to be considered. Of course we are aware that in severe glycosuria dextrose may be formed from albuminous tissues, and even from fat to a slight extent, but the most important sources of dextrose are admitted by all to be the other carbohydrates. Physiologic chemistry has hitherto been unable to follow the carbohydrates beyond the dextrose stage, and there has consequently been a gap in our knowledge between the stage and the final assimilation by the tissues; or rather, the consensus of opinion seems to be that normal tissues absorb dextrose as dextrose, without further transformation. From this idea a theory to account for diabetic phenomena was formerly advanced postulating disturbance in the tissues of the function to absorb dextrose. But there is evidence on record strongly implying that dextrose does not express the final effort of Nature in the preparation of the carbohydrates for nutritive purposes.

In 1892 Lépine found that fresh normal blood, after being kept in an incubator at physiologic temperature for some time, contained decidedly less dextrose than at the beginning of the experiment. In diabetic blood under the same conditions the loss in dextrose was not so pronounced. While not as yet confirmed, that I am aware of, by later workers, this demonstration not only receives confirmation from some of much earlier date, but is thereby actually much extended. Lépine's work in this direction seems to have proceeded no farther than the observation that dextrose was lessened in amount in blood which had stood some time at normal temperature. It stands to reason that if dextrose is diminished under such conditions something else must be formed. The next thing, then, to determine is, if possible, what this something is, and therefore another series of experiments will now have to be referred to.

In 1872 Ford made a number of careful tests and elaborate calculations in relation to postmortem chemical changes occurring in normal blood and tissues. He worked on the theory that sugar is first converted into alcohol before it is possible for the tissues to derive benefit from it. In a large number of experiments a substance resembling alcohol, physically and chemically, was invariably recovered in minute amounts from fresh blood and tissue; from putrescent blood and tissue a much greater amount of this substance was always obtained. The amount obtained by experiment corresponded approximately to the amount of alcohol calculated, based on the amount of carbon ingested and on that exhaled. The smallest amount of alcohol was obtained from fresh liver tissue, and by far the largest from putrescent liver tissue. It is hardly conceivable that this alcohol, if such it was, resulted from anything else than the dextrose in the circulation, and in the case of the putrescent liver tissue from the store of glycogen previously liberated as dextrose. The tests on which Ford relied to demonstrate that the substance he obtained was alcohol were the usual ones then known to chemistry.

Ford's remarkable researches received corroboration in the main idea in 1873, when Dupré and Béchamp—it would appear independently—discovered a substance resembling alcohol in normal urine, and from persons who had not exhibited alcohol for a long time. This discovery is also said to have been first made by Lieben in 1870, and he also observed the phenomenon in the urine of dogs, horses and lions. In 1875 Rejewski obtained the substance from the urine of rabbits.

The statement that the substance found by Ford and the others was really alcohol, has been contested, as might naturally have been expected. The substance in question responded to the chromic acid test and the iodoform test; its watery solution had a lighter specific gravity than water; it yielded acetic acid on oxidation; and concentrated solutions were inflammable; the optical appearance in the conducting tubes, as noticed by Ford, resembled that of alcohol. Commenting on the fact that this physiologic substance reacts to all the known tests for alcohol, H. C. Wood very pertinently observes that "possessing the physical and chemical characters of alcohol, to ordinary minds it is alcohol."

The experimental testimony is conflicting as to the exact place of alcohol as a nutritive agent, its relation to heat production, electro-chemical action, carbonic acid and urea elimination, etc. But there is no question of the fact that alcohol is burnt up, or loses its identity, in the system, and that practically none of that ingested is eliminated as alcohol, unless administered in toxic amounts. It must be capable, therefore, of supplying, to an extent, the needs of the organism in health, and far more so in some pathologic conditions—a matter of every-day clinical experience.

In the light of present knowledge it would appear probable that the asserted conversion of dextrose into alcohol in the system is effected through the agency of an enzyme normally present therein. Our own experiments along this line, made in 1901-1902, are now in order. I am under obligations to Surgeon P. M. Carrington, in command at Fort Stanton, N. M., for extending to me such privileges as the laboratory of that station afforded while engaged in this work.

Solutions of dextrose, sterilized by boiling, were treated when cool with pancreatin preparations, and then set by in a warm place. After a number of hours small portions of the mixtures were distilled off and subjected to the iodoform and chromic acid tests for alcohol, giving in each case a positive reaction. More solutions were prepared and analyzed quantitatively, before and after prolonged treatment with pancreatin, to determine if any variation occurred in the percentage of sugar. A large number of these tests demonstrated a slight loss of sugar in nearly every case after having been acted on for some time by the pancreatin. Solutions of levulose tested before and after in the same manner showed a greater proportional loss of sugar than did those of dextrose. It seems hardly necessary to add that in each experiment the amount of water lost by evaporation during the period of fermentation was replaced by distilled water before reanalysis; and that the differing affinities of dextrose and of levulose for copper hydroxid were taken into account. Solutions of cane sugar treated with pancreatin gave, in their distillates, the iodoform and the chromic acid reactions for alcohol. The vapor from a dextrose and pancreatin solution imparted a slight cloudiness to lime water, but as the experiment was rather carelessly made; and, unfortunately, was not repeated, it can not be considered as positive. Pancreatin itself contains considerable soluble material capable of reducing copper solutions, and this self-contained reducing agent undoubtedly took some part in the fermentative processes. Being apparently for the most part dextrose its presence should not detract from the importance of the other findings, except in the instance where an alcoholic distillate was obtained from a cane sugar and pancreatin solution. A strong point against any undue importance of this factor in the other experiments is that dextrose and levulose solutions did not lose in sugar proportionally, and that the variation in the levulose was inversely what might have been expected from ordinary accidental fermentation.

Assuming, then, the correctness in the main of all the experimental findings herein adduced, the situation physiologically would appear thus:

1. That in normal blood dextrose undergoes chemical modification before absorption by the tissues.
2. That in normal blood alcohol develops from disintegration of dextrose.
3. That alcohol is present in minute quantities in the urine of total abstainers.
4. That in chemically pure solutions of dextrose and levulose treated with pancreatin, sugar is lost and alcohol (and carbonic acid?) developed, the change being more marked in the case of levulose.
5. That the agent responsible for the chemical reaction is an enzyme normally present in blood.
6. That this enzyme has its origin in the pancreas alone, for when that organ is removed dextrose remains unchanged.
7. That interference with or disturbance of this function of the pancreas initiates a group of phenomena known clinically as diabetes mellitus.

### SOURCES OF ERROR.

It is true that at the present time much of the experimental data referred to lacks corroboration by other observers, notably that of Lépine, Ford, and the present writer. I have not seen Ford's original paper, being indebted to the section on alcohol in H. C. Wood's Therapeutics for a synopsis of his results, and also much additional valuable information. But that there were sources of error in Ford's work seems probable when it is remembered that in his time bacteriology as a science hardly yet existed, and that therefore he may not have taken into account the action of saprophytic bacteria in the change from dextrose to alcohol. In this way it is likely that his results with putrescent tissues were partially erroneous. But in view of the very significant fact that he obtained traces of alcohol from fresh blood and tissue, the importance of any possible errors in connection with tissue having undergone bacterial action ought not to be exaggerated.

Such objections, however, can not be urged in regard to Lépine's results, for they were reached at a time when the principles of modern bacteriology were familiar to all contemporary scientists. Though Lépine is not on record, that I am aware of, as having demonstrated alcohol, he certainly has demonstrated the complementary fact, namely, the disappearance of dextrose in normal blood, and to a lesser extent in diabetic blood. Lépine's and Ford's separate blocks of evidence, when placed side by side, form a chemically perfect whole, the former having shown that sugar disappears, the latter that alcohol appears. Collateral testimony is afforded by the work of other investigators cited who demonstrated the presence of traces of alcohol in normal urine.

In our own work, which had for its object the demonstration of a pancreatic enzyme able to convert dextrose into alcohol, the principal source of error was infection of the solutions with saprophytic bacteria. By a process of exclusion it was made evident that the infection was derived from the commercial preparations of pancreatin, a fact of no importance whatever ordinarily, but of considerable in experiments of this nature. In only two instances were perfectly sterile solutions made naturally. Efforts were then made to control bacterial action by means of small amounts of boric acid, oil of cloves, etc. It was found that in order to suppress saprophytic action much more of these substances was required than is currently believed, so much, in fact, that the action of the enzyme was nearly inhibited. By comparing the notes of a large number of experiments under these adverse conditions it was shown, however, that a slight loss of sugar nearly always resulted. The source of error here, if there was one, would have occurred in the manipulation, toward the end of each test, of the Fehling solution, by no means an ideal method where small differences have to be computed, but perhaps the best in the long run. The levulose preparations showed a greater loss of sugar than did those of dextrose. In solutions of either sugar with pancreatin where no antiseptic had been added, and where saprophytic action occurred, the loss of sugar in a given time was far greater, especially in the case of levulose. The infecting organism most in evidence was a large spore-forming chain-rod, generally alone, occasionally accompanied by other germs in small numbers. The yeast fungus was not found to be present at any time.

How much of the large amounts of sugars lost here, in excess of that lost where bacterial action was inhibited by antiseptics, depended upon the pancreatic enzyme, and how much was due to bacteria, we are unable at present to say, and can place reliance only on the results obtained where the action of bacteria was eliminated. It is certainly worthy of note, though, that the corresponding losses of dextrose and levulose under the same conditions of infection were so widely different as to imply something more at work than bacterial action alone.

Among the number of experiments made to demonstrate the development of alcohol were two in which, fortunately, no infection occurred and no antiseptic was employed. In these cases the principal source of error to be considered would have been in the chemical tests to which the distillates were subjected. Both the iodoform test and the chromic acid test are well known to react in the same manner with many substances besides ethyl alcohol. In this connection it was observed that the chromic acid test gave the same color reaction with methyl alcohol, dextrose, levulose, lactose and cane sugar. Seeing that both tests gave typical reactions with material derived from sources more likely in the natural order of things to generate ethyl alcohol than anything else; and seeing that such a result fits in very naturally with Lépine's and Ford's results; it must be admitted that strong reasons exist for presuming the reacting substance to have been alcohol.

An attempt will now be made to account for diabetic phenomena on the theory that they are the expression of an abnormal condition wherein the hypothetical alcoholic function of the pancreas is disturbed.

### DIABETES MELLITUS.

If it is a fact that the normal internal secretion of the pancreas must convert dextrose into alcohol before the tissues can make use of it, then it naturally follows that a consideration of this obscure function would have importance in relation to true diabetes mellitus of pancreatic origin, as our knowledge stands at present. The various and diverse manifestations of the disease, when considered in this light, seem to fall easily into well-defined places, while at the same time theories placing the responsibility on other organs are seen to be untenable. These remarks are not intended to apply to other than pancreatic forms of diabetes, or glycosuria, for we believe that such may occur, and will venture a few remarks on them in their proper place. We will begin the discussion with the behavior of the liver in reference to pancreatic diabetes.

The most significant feature here is the absence of glycogen, practically, in the liver and muscular tissue. This, together with the notable excess of dextrose in the blood, suggested at least three theories, two implicating the liver; the first for over-activity, the second for under-activity; while the third placed the blame on the tissues in general as having partially lost their power to absorb dextrose. The pancreatic alcoholic theory at once clears up all this; the liver is seen to be merely doing its duty while the tissues, being unable to assimilate the unaltered dextrose furnished by the liver, are imperatively and without intermission demanding nourishment. But the nervous mechanism, which in health had apprised the liver of the needs of the tissues, is still uninjured, and the constant demand for food is as constantly responded to by the liver in the only way it is capable of doing; it has no time to store up glycogen, and the fact that the excess of dextrose given out is injurious to the organism implies no fault in the liver whatever, but actually the reverse. If the liver were the seat of the assumed normal alcoholic change in the condition of dextrose, then there would be found no free dextrose in the blood except in minute amounts like glycogen, for all sugar would be immediately seized and stored up as glycogen, never to be released except in the form of alcohol.

The existence of glycosuria and polyuria, without other evidences of nephritis, is merely symptomatic; the glycosuria because the normal percentage of sugar is exceeded, and the polyuria because of the irritating action of dextrose on the renal tissue. Secondarily, of course, a true nephritis will probably occur if the condition is not ameliorated.

The remarkable and inexplicable property of levulose to form glycogen and diminish glycosuria can now be explained. Levulose is more rapidly and easily converted into alcohol than is dextrose by the pancreatic enzyme, and the reduced amount or power of the latter in diabetes is thus able to take care of considerably more levulose than dextrose, and the liver and muscular tissues are enabled to store a certain amount of glycogen.

As milk is comparatively well tolerated in diabetes, it follows that lactose must have properties somewhat similar to those of levulose. I have not experimented with lactose as with levulose, but would expect to find it somewhat similar in this respect. It is noteworthy that there is a curious analogy in the purely chemical and the purely physiologic contrasting properties of dextrose on the one hand, and levulose on the other. A definite amount of copper hydroxid will combine with more levulose and still more lactose than with dextrose; in physiology, on our theory, levulose and lactose are more readily appropriated by the system than is dextrose, the fact being especially noticeable in diabetes mellitus.

The increased elimination of urea and uric acid is natural and proper, since in this disease a larger amount of albuminous material is employed, irrespective of the kind of food ingested, for if that is lacking in proteids the deficit is made up from the tissues themselves.

The fatty condition of the blood is apparently a further effort of Nature to store glycogen and form dextrose. It has been shown that fat in extreme conditions, as in starvation, can form glycogen, and therefore indirectly, dextrose. Diabetes mellitus is merely another aspect of starvation. The greater part of the large amount of food ingested is useless to the organism, for the system is lacking in the element whose presence alone can render it available for its needs. The condition has its analogy in the fable of Tantalus, striving forever to sip "The cup that flies from his arid lip."

The tendency toward acidity of the blood in later stages of the disease, with the development of acetone, diacetic acid and beta-oxybutyric acid, may be referred to several causes. The alkalinity of the intestinal tract depends principally on the bile and pancreatic juice. The liver being constantly overtaxed in the exercise of the glycogenic function and the preparation of proteids and elimination of urea, must in time neglect the biliary function as being subordinate to the others in importance; while the pancreas, diseased in one of its most important functions, can hardly be expected to keep up the standard of its intestinal secretion. It follows consequently that the intestinal juices become in time deteriorated, thus favoring the development of acetic and lactic and other acid substances. These eventually begin to enter the portal circulation, and, after a time, the general circulation, and ultimately change the reaction of the blood. The normal power of the liver to arrest and render harmless the poisonous substances developed in the intestines, becomes diminished, and these adding their baneful influences to that of the general hyperacidity, finally give rise to comatose symptoms.

### OTHER FORMS OF DIABETES. RENAL GLYCOSURIA.

There is evidence showing the possibility of diabetes in some cases arising from the kidneys themselves. In the first place, albuminuria and different degrees of nephritis have been observed in perhaps one-third of all cases of diabetes, while definite pancreatic lesions have hardly occurred in more than 50 per cent. of cases.

While in many of the cases exhibiting renal involvement the pathology may be merely secondary to pancreatic disease, it can not always be proven that such is the case. In the series of experiments of which the one employing phloridzin is the type, we are shown that renal diabetes is a possibility, either as resulting from disturbance of osmotic equilibrium, or it may be, of the renal synthetic functions. The fact that severe forms of Bright's disease do not often show glycosuria, complicates the inquiry, and supports to some extent the theories relieving the kidneys of responsibility in glycosuria. The question of renal involvement will be again alluded to under the head of therapeutic suggestions.

### GLYCOSURIA OF NERVOUS ORIGIN.

That pathologic conditions involving the nervous system can induce glycosuria has been shown experimentally and clinically; but even here the glycosuria must be indirectly referred to the agency of one or more of the internal organs whose ordinary routine has been disturbed by disturbance of its innervation. The osmotic balance of the kidneys may be disordered; the glycogenic function of the liver, the alcoholic function of the pancreas, or the internal secretion of the adrenals —perhaps also that of the thyroid—may be altered. Thus it may be inferred that defective innervation can, theoretically, inaugurate glycosuria through a number of sources.

### ADRENAL DIABETES.

With the discovery of the power of adrenal extracts to cause glycosuria (and to convert starch into dextrose?) a new and interesting element was added to the subject of diabetes. By applying these facts to the present inquiry, together with the known physiologic action of the glandular extract, and assuming the existence of a condition of the adrenals causing over-production of their internal secretion, it would appear that glycosuria may be induced in four different ways, or by a combination of one or more of them, namely, by increased blood pressure; by irritation of the renal parenchyma; by inhibition of the alcoholic function of the pancreas; and by direct action on the stored up glycogen, converting it into dextrose.

In the event of under-production of the adrenal secretion we might assume that one of the first compensatory efforts of Nature would be stimulation of the alcoholic function of the pancreas, the object being to make up the deficit in adrenal secretion by an increase in the production of alcohol, for the physiologic action of the latter ought to enable it to partially substitute the former temporarily. Such a possible substitution has its analogy in the splitting up of the proteid molecule with the formation of an alkaline ammonium compound when from any cause there is a tendency toward acidity of the blood which can not be controlled by the alkaline substances normally present. But since over-stimulation of any organ tends eventually to loss of function, it would follow, on this theory, that a time would come when the pancreas could no longer exercise its alcoholic function sufficiently for the needs of the system. Then the liver would endeavor to supply the want by liberating an increased amount of dextrose, and it would then be only a question of time when glycosuria and the concomitant symptoms of pancreatic diabetes appeared. It may be reasoned in this way that the pancreatic and adrenal functions are intimately related; the adrenal secretion may be essential in regulating the exercise of the pancreatic alcoholic function in health, while in the event of insufficiency of the former the latter would be stimulated.

### EXPERIMENTAL CONFIRMATION.

It is much to be regretted that confirmation by other observers is yet lacking of much of the data essential to the theory herein advanced. Even Lépine's results, significant as they are, do not seem to have received corroboration; while Ford's work is never alluded to in treatises on diabetes and seems to have escaped attention altogether. My own work is very incomplete at best, but as far as it goes I feel that it can not be altogether unimportant, and trust that it will soon be taken up by others, along with Lépine's and Ford's observations. I intended to submit my results for publication early in 1902, as soon as the series of experiments outlined should have been finished. But unforeseen interruptions occurred and official duties in connection with the routine work of the Sanatorium interfered; and as there is even yet no immediate prospect of my being able to resume the experiments, I have decided to submit such as have been made, together with the theory they suggest, in the hope that the work may be investigated and extended by others, and its value, if it possesses any, be determined.

Because of the presence of saprophytes in the commercial dried preparations of pancreatin, I would suggest that they be discarded in experiments of this nature, and that the fresh organs of animals recently killed be employed. The amount of dextrose or reducing substance in the gland itself or its extract should be determined before treating the sugar solutions. Sufficient alcoholic liquid should be obtained so that its physical and chemical characters can be established with certainty. In the chemical equilibrium of the system the amount of alcohol present must be very small at any time compared to that of dextrose, and therefore in any experimental solution the relative proportions may be expected to approximate similarly; for the principle of "reversibility of enzymes" should be in operation here as elsewhere in the system. If alcohol is really formed the amount should of course bear definite relation to the amount of sugar lost. The fact that small quantities of alcohol are produced in the intestines should not be ignored even though it can not have great significance here, since alcoholic development occurred under conditions excluding intestinal co-operation. The reactions with levulose and lactose should be particularly noted because of their peculiar properties in diabetes mellitus. In all cases control tests would be imperative. The action of adrenal extracts on sugars and starches ought also to receive further attention. The fact should be taken into account that the pancreatic alcoholic enzyme must be present, not only in the pancreas, but throughout the system to a certain extent. It has been asserted that glycerin may assist in the formation of glycogen; it would also be worth while to investigate the behavior of ingested alcohol in regard to that function, remembering that Ford found less free alcohol in fresh liver than in any other tissue. In testing diabetic material for alcohol one would expect to encounter much less than in the normal, perhaps none at all. The chromic acid and iodoform tests would be valueless here because of the likelihood of the presence of acetone, a substance giving the same reactions as alcohol with these tests.

### THERAPEUTIC SUGGESTIONS.

If the theory set forth here is the correct one, then the importance of alcohol in the treatment of diabetes is the most obvious feature that presents itself. Based on clinical observations, the best authorities are already nearly agreed as to the beneficial influence exerted by alcohol in diabetes when given in moderation. Clearly on our hypothesis reasonable amounts of alcohol will relieve the pancreas, liver and kidneys for the time being by furnishing ready prepared nourishment and force to the starving tissues; there will be temporary suspension of the immense and constant and all but unavailing efforts of those organs to relieve the strained situation. Very possibly some storage of glycogen may be accomplished during the period of relief thus afforded.

With regard to the administration of pancreatic extracts, Von Noorden and others have not had very encouraging results. Only two methods would appear available in the employment of these preparations. One way would be to give them with or immediately preceding meals, the idea being to take advantage of the presence of the alkaline saliva, since pancreatin can not act in acid media; the doses should be large in order to assure the absorption of an amount of the enzyme, for the major portion would soon be destroyed in the stomach. The other way would be incorporation in alkaline nutrient enemata and injection into the rectum or colon.

I have seen great apparent benefit follow the use of mescal de tequila in two cases, both of them young subjects. Whether this was merely from the alcohol present, or because of specific properties possessed by the drink, I am unable to say, though inclined to put some faith in the latter possibility.

Mescal is a fermented intoxicating liquor derived from the *maguey* plant, native to southern New Mexico, Arizona and Old Mexico. The unfermented juice of the plant is called pulque, and it, as well as mescal, has a great reputation among the natives as a specific for all "kidney" diseases, pulque being the most thought of. With them diabetes is naturally considered a disease of the kidneys, but there really appears to be some firm ground on which the popular faith in the drug rests, both as regards diabetes and Bright's disease. That it exerts some special influence on the kidneys is certain. In several cases of Bright's disease experimented on at Fort Stanton, N. M., it was found that chronic interstitial cases were much benefited in a short time, both as regarded the amounts of urine and albumin. Chronic parenchymatous cases were also speedily brought under the influence of the remedy, showing lessening of albumin, but there was at the same time a tendency toward suppression which had with it an element of danger. The cerebral effects of overdoses were unpleasant and were induced by much smaller amounts than mere whisky would have done.

In this connection I have to acknowledge my indebtedness to Dr. H. K. Pangburn, Acting Assistant Surgeon, and to Mr. J. E. Beck, Senior Pharmacist, U. S. M. H. S.; the former for daily quantitative urinalyses in the cases under observation; the latter for pharmaceutic preparations of extract of the maguey plant.

In view of its effects in Bright's disease, and remembering the possibility of renal diabetes, the suggestion may be hazarded that while the specific action of the maguey plant on the kidneys would perhaps account for its beneficial action in cases of diabetes of renal origin, it might not possess any value in the true pancreatic variety.

### ETHICAL CONSIDERATIONS.

The assumption of the existence of the alcoholic function of the pancreas, on account of its relation to nutrition in general, diet, habits, and the treatment of diabetes, brings up a final and important consideration, namely, the question of intemperance.

It has been suggested that were a theory such as this one to become generally accepted it would probably exert a baneful influence on the race in general by furnishing a physiologic excuse for increasing the consumption of alcoholic beverages.

When looked at superficially such a fear might seem reasonable; but when examined more critically it is seen to have no foundation.

Everyone is aware that perfect physical health means nothing more or less than perfect functional activity as established by Nature's immutable laws. All efforts made by man to modify these functions have signally failed, and no matter what abnormal extent of tolerance may have been achieved by the pleasure seeker, the epicure or the heavy drinker, their reckoning with Nature must come at last, for they have reckoned without their host.

The man would be a poor physician indeed who saw fit to recommend to his patients the consumption of unusual amounts of cheap glucose candy in place of a portion of their ordinary diet, because he had learned in the study of physiology that glucose represented an advanced effort of Nature in the preparation of the carbohydrate food group.

Exactly the same may be said in the case of alcohol and of the medical man who would advise the employment in health of alcohol as a substitute for a certain amount of food, because alcohol appears to be the final product of an important section of the foods, and, by such specious reasoning, more easy and natural to assimilate than ordinary foods. Nature has made abundant provision and has combined the various nutritive principles in a manner that can not be improved on in the essential particulars. No matter what the advance made in our knowledge of physiologic chemistry, mankind still have to depend on Nature's unvarying processes for their continued existence, and, physiologically, are neither better nor worse than they were ages ago. The natural processes involved in digestion, nutrition and assimilation are not intended to be altered in any way, either by increasing or lessening their scope. The fact that foodstuffs occur in forms that require such extensive elaboration in the system is sufficient evidence of the wisdom of such an arrangement.

When considered in this light it will be seen that the alcoholic theory in physiology is in reality a strong argument in favor of temperance. In health man needs no ready prepared alcohol whatever, except such as occurs naturally in some of the foods in small quantities.

But the situation is very different indeed when the management of disease has to be confronted. If alcohol is a physiologic necessity, as produced in the body in health, then it follows that in the treatment of many diseases its employment as a medicine would be of the greatest possible advantage to the patient. The most obvious indications for its administration would be in those pathologic conditions wherein the mysterious protective agencies are summoned to exercise their functions to the utmost limit in order to cope successfully with some foreign invasion or auto-intoxication which menaces the integrity of the system. Nearly every medical man of experience will concur in the opinion just expressed; while as regards the few who see fit to exclude alcohol altogether, on the ground of religious or other principles, no amount of argument, laboratory experiment or clinical experience, however convincing, can be expected to have weight.

In conclusion, then, from the standpoint of the alcoholic theory in physiology, based upon experimental and clinical results, it would appear that in alcohol we possess the most efficient agent for sustaining the vital forces of the system when its functional activities are paralyzed by the inroads of various diseases, whose presence necessitates the subordination of all other functions to those immediately engaged in the work of repelling the invasion.

---

## RADIUM AND RADIANT ENERGY.*

JOHN INGLIS, A.M., M.D.

Member Colorado State Board of Medical Examiners.

PUEBLO, COLO.

The discovery of radium is of universal interest. There is scarcely a science that has not been affected by it. But it can be of no greater interest to any one than to physicians, because of its therapeutic possibilities. The termination "um" indicates that radium has been added to the family of elements.

A substance to be admitted into the list of elements must have the following qualification: It must have a spark spectrum of its own. This spark spectrum must be measured and be different from all other forms of known matter. Radium fulfills this requirement. Demarcay has shown that radium has a spark spectrum of fifteen lines, with no lines belonging to any other element. The discovery of radium during the closing years of the nineteenth century was one of the most wonderful achievements of that century, from a scientific point of view. In some ways it amounts almost to a revolution in our theory of matter. The study of physics and chemistry has made the most rapid progress of any of the sciences in the past few years. The textbooks which the youngest of us used are out of date, so rapid have been the changes and progress along this line of study.

So it may be well to note, in introducing this subject, some of the more essential changes, without understanding which we can not gain a clear idea of the subject before us.

We were taught as school boys that that smallest particle of hydrogen, called an atom, was the least mass of matter known. Since that time, however, Thomson has discovered that all space is filled with inconceivable small corpuscles. These corpuscles, Professor Larkin tells us, are doubtless either electricity in its ultimate refinement or very closely allied to it. A Thomsonian corpuscle is only 1/1000 the mass of an atom of hydrogen. They are so small that the wide spaces in a bar of steel or even in the diamond itself, permit these corpuscles to pass through them. They are positive or negative, electrically speaking. But the corpuscles flowing between all kinds of matter are negative.

Twenty-five hundred years ago Leucippus, the Greek philosopher, suggested the atomic theory of matter. Dr. John Dalton, at the beginning of the nineteenth century, formulated it into the hypothesis which we find to-day. This theory assumed that all matter is composed of indivisible particles called atoms.

---

* Read before the Pueblo County Medical Society.

The Italian philosopher, Avogadro, proposed the molecule as the smallest particle of matter which exists in a free state.

The discovery of radium practically establishes the Thomsonian corpuscle theory. We are now taught that small as is an atom, we must look for a particle of matter thousands of times smaller. This particle, so much smaller than the atom, is called an ion. The ion revolves around its fellows at a tremendous rate of speed. These ions of matter are now considered the smallest particles known, being 1,000 to 200,000 times smaller than an atom. Ions compose the atoms and enable them to act chemically.

Science at present holds that matter is made up of masses of ions revolving in their own orbits. That smallest atom of hydrogen is composed of 700 ions. An atom of oxygen contains 11,200 ions. Iron contains 187,000 ions to an atom. An atom of radium contains 120,000. In radium, these ions rotate so swiftly that a violet light is given off. All space is traversed by unknown radiations, and these are arrested in their passage through radioactive substances and transformed into radioactive energy. Radioactive is a recently coined word, but no treatise on physics can be written to-day without it.

Matter, such as barium, uranium, zinc, aluminum, gives out obscure undulations. Radioactive matter gives off these undulations in straight lines in every direction. When matter is in a state allowing it to be active by means of a wave motion, it gives off these undulations. Since the corpuscles that flow between the atoms of matter are negative, they may be drawn out of this straight path by the action of magnetism. This confirms what Maxwell claimed almost half a century ago, that the wave motion of the universe is electromagnetic. Whenever there are 34,000 of these electromagnetic undulations within one inch of space, we see light. If 61,000, we see a violet light. In the spectrum the length of each oscillation is by itself and can be measured.

These waves form a fundamental fact in the study of science to-day. At the very beginning of the seventeenth century, Kepler placed a prism in a ray of sunlight and produced a solar spectrum. About 100 years later, Newton placed a prism in a ray of sunlight admitted into a dark room, thus gaining a much clearer line. At the beginning of the nineteenth century, Wollaston admitted, like Newton, a ray of light into a dark room, but through a very narrow slit, and placing a prism in it, obtained the dark lines in the spectrum. Fraunhofer, a few years later, did what Wollaston had done, but looked at the spectrum with a small telescope. This gave us a spectrum analysis; and spectrum analysis has been one of the greatest studies of the human intellect from that day to this. The discovery of such elements as radium we owe to spectrum analysis.

Three centuries of study and research have discovered only two things apart from mind, in this universe, namely, matter and energy. Since the recent discoveries of the former, no one will venture to say that we have reached the ultimate analysis. Of the latter, energy, recent discoveries are apt to make us feel that our whole conception of work, force, energy, will have to undergo some radical revision. At least, that we are in the infancy of knowledge regarding what we call energy, and to-day a definition is wanted for the question: What is energy?

In 1896, Becquerel discovered remarkable radiation from a sample of uranium. He found that any preparation of uranium emitted continuous radiations. These radiations, he discovered, were similar to the *x*-ray and capable of acting on a photographic plate chemically. The name, "Becquerel rays," has been given to these radiations. Following up the investigation of these Becquerel rays in uranium, M. Curie and Madame Curie discovered from samples of uraninite, that the radiations from it were more powerful than any uranium with which they had experimented. They found this uraninite or pitchblende, as it is commonly called, to have four times the radioactivity of metallic uranium. From this M. Curie came to the conclusion that this radioactivity was due to some new element in the pitchblende. A series of experiments ended in the discovery of a new radioactive substance. This was in 1898. Further experiments succeeded a year later, in 1899, in finding radium.

Radium belongs to the alkaline group of elements, such as calcium, strontium, barium. It has a specific affinity for barium. Madame Curie gives the atomic weight of radium as 225, while barium is 136.4. Radium is obtainable from pitchblende, which is found in Saxony, Bohemia, Cornwall in England, and in Colorado. Uraninite or pitchblende is a heavy, black, pitchy-looking substance. It is composed of two oxids of uranium, with a number of other elements in small amounts. This pitchblende is the source of uranium, but in extracting the latter a residue of rare substances has always been left unused. Uranium compounds have been used to stain glass and porcelain, also to make dye-stuffs, and is of use in photography. M. Becquerel found that uranium exposed to the sun's rays apparently absorbed them. Further experiments, however, showed that pitchblende decomposed the silver salt on a photographic plate. This produced a stir in the chemical world, and it was soon evident that pitchblende contained some substance which could produce photographic images in the dark. This much of the honor in discovering radium belongs to M. Becquerel, the noted French chemist. At this juncture, M. Curie, the physicist, and his wife, began the search for this new element, which Curie was satisfied this uranium ore contained.

Madame Curie was the more enthusiastic in this search, and it is said that it was she who induced her husband to join in the search, which finally resulted in the discovery of polonium, then of radium. They attempted by various experiments to separate this new element or substance in pitchblende, and found not one but two substances. The first one found, Madame Curie named polonium, after her native land, for Madame Curie was born in Poland, and it was as a student in Paris that she met her husband-to-be. The second new substance, they named radium, from radius, a ray, on account of its remarkable radiations. The complex chemical methods by which this substance was separated belongs to a society of chemists, not of physicians. The object now is to find ores which may contain traces of radium. It may be that in the mines of Colorado this element may be found, and to-day it is of far more value than either gold or diamonds.

Just here it is interesting to note in passing that the discovery of radium, like all great scientific discoveries, was found along a well-paved way—something like the discovery of the planet Neptune. Recalling our lessons in astronomy, we remember that Neptune was found because, after the discovery of Uranus, astronomers felt that the erratic course of that planet could only be accounted for by the action of another body acting on it. Following out this line of reasoning led those who nightly watched the heavens through powerful telescopes to search for a new star which was exerting its influence on Uranus, and after a diligent search of space, Neptune was located, the planet which was known to exist before it was found.

The peculiarities of uraninite led M. Curie to the belief that it contained some yet undiscovered mineral. The study of physics and chemistry by scholars during the past ten years ending in the discovery of the *x*-ray, the Crookes tube, the ultraviolet ray, the discovery of Becquerel rays in pitchblende, led by a natural process of evolution to the finding of radium.

To Madame Curie, the wife of the noted physicist, belongs the honor of separating radium from its ore. And while her husband shares with her the honor of the discovery, and she herself has been known to the scientific world as the wife of Professor Curie of Paris, M. Curie now stands in danger of being known to the readers of popular magazines as the husband of Madame Curie. The separation of radium from pitchblende marks the greatest contribution to any science made by womankind. Madam Curie has since been given the degree of Ph.D. by the College of Science in Paris as a recognition for her work along these lines.

### PROPERTIES OF RADIUM.

As yet radium has only been obtained in the form of a salt. Many forms of glass are turned violet by its action, but it is supposed that this is due to some chemical action on the iron and manganese used in making glass. It has been kept in rock crystal for thirty days without producing any changes in the crystal. One of the most remarkable properties of radium is that it maintains a temperature of 2 to 5 F. above the surrounding atmosphere.

Radium action will pass through four or five inches of oak with the greatest ease. The process of measuring radium energy is too elaborate to explain in a paper of this length. It is common, however, to speak of radium as having an activity of 100,000 or 200,000. This means that taking metallic uranium as a unit of measure for radioactivity, radium has a certain activity equivalent to 1,000, or 100,000 times greater than that of uranium, as the case may be. Radium has been used to distinguish a pure diamond from stones that resemble it by its radioactive effect on the diamond, not producing the same result in the spurious stone. Radium decomposes the silver salt on a photographic plate. The rays from radium act like the *x*-ray in penetrating opaque substances. One grain of radium will melt a grain of ice every hour. In other words, it will melt its own weight of ice per hour. This production of heat will go on constantly without any apparent source, and at the end of months, the radium will be as powerful as ever. Long months of activity show no change in the grain of radium. Its weight remains the same; there is no chemical, microscopic or spectroscopic change. It is impossible for us to believe that this minute mass of matter can give off heat for so long without in some way having it restored or renewed. The explanation of this phenomenon is yet to be found, but it is possible—and this is only a suggestion—that in some way unknown to us radium has the power of absorbing this from the Thomsonian corpuscles.

### PHYSIOLOGIC EFFECTS.

Becquerel carried a small particle of radium in a glass tube in his vest pocket. It set up a dermatitis, followed in three days by a burn, and from this an ulceration resulted, taking about two months to heal. A tube containing radium attached to the back of a mouse resulted in its death in twenty-four hours. A few milligrams put beneath the skin of a mouse resulted in its death in three hours. Placed over the closed eyelids, a tube of radium gives a sensation of light. Seeds subjected for some time to the radium influence lose their power of germinating.

The most wonderful property of this new substance is its energy, but, as has been said, the source of this energy is unknown. It seems to possess almost the power of perpetual motion. Two hypotheses have been suggested to account for this energy. One is that the atoms of radium evolve and transform into another simple body, although this transformation can not be located during a year's time. This is the hypothesis suggested by Madame Curie. The other is that radium is capable of utilizing some radiations of unknown nature which cross the space. Experimenters find great difficulty in keeping their instruments free from the effects of this radiant energy. Professor Curie says he would not trust himself in a room containing a kilo of pure radium for fear it would burn the skin off his body, destroy his eyesight and probably kill him.

Radium makes all substances brought in contact with it more or less radioactive. There is this difference between radiant energy and the energy of the *x*-ray: Radium induces an activity which persists, while the activity of the *x*-ray ceases on the removal of the rays. Lord Kelvin is quoted as saying that the discovery of the Becquerel rays from radium and other such substances has placed the first question mark against the principle of the conservation of energy, which has hitherto been supposed to be an incontrovertible fact in science.

### RADIUM IN MEDICINE.

Sir Henry Crookes has carried out some experiments which show that radium has marked bactericidal properties. Caspari exposed cultures of the *Micrococcus prodigiosus* to a preparation of radium which destroyed the germs in three hours. Soddy of England has suggested the inhalations of the emanations of radium for consumption. Tracy of New York has very recently carried out some experiments in induced radioactivity He finds a normal salt solution one of the best media for receiving this radioactivity. This property suggests the hope of finding an effective way of using it internally. A spray of the normal salt solution impregnated with radium will leave the mucous membranes of the nose and throat covered with this radioactive matter, which is antiseptic to a marked degree. It may turn out to have a powerful effect in the relief of cancer of the stomach. Surgical dressings may also be sprayed with radioactive salt solution.

It has already been clearly proven that radium rays have a very decided influence in inhibiting the progress of diseased tissue. These emanations of radium seem to offer some advantages over the *x*-ray in the treatment of deep-seated cancer. The *x*-ray has not been a success in this affection. Owing to the penetrating power of the emanations of radium, it will be possible to apply these rays to the seat of the disease. I have found reports of the following cases:

MacIntire of Glasgow reports two cases of lupus—one of the hand, one of the nostril and nose—both of which were healed by the radium ray. MacIntire also reports favorably of its use in rodent ulcer.

Gussenbauer of Vienna reports good results and some cures in twenty cases of cancer treated by him.

Lunder of Berlin claims to have had good results in cases of blindness from the stimulating effect of the radiations on the eye. It may be that this new agent will prove valuable in these hopeless cases of optic nerve atrophy.

Tracy also reports a case of epithelioma improving under the influence of a tube of radium of 300,000 activity containing ten milligrams. The same physician has also tried this tube on a case of optic atrophy in a man 52 years old. Some improvement has taken place, though the patient is still under treatment. Dr. Blandamour, using a tube of radium with an activity of 5,200, reports the cure of lupus.

Dr. Meyer and William J. Hammer improved a large axillary cancer with radium of 300,000 activity. The exposure was one minute daily. While this case was incurable, the cancer grew smaller and less painful under the rays.

Dr. A. H. Smith reports having seen in a European clinic a rodent ulcer perfectly healed after five exposures, though this ulcer had been treated by the *x*-ray without benefit.

The place of this new element as a therapeutic agent has yet to be determined. At present the cost of it and its scarcity prevent it coming into general use. But if it can be found even in limited quantities, it will have this advantage of the *x*-ray: It will require no costly apparatus—merely a test tube. It will be free from expense of wear and tear. It can also be carried anywhere for use.

This is a newly discovered force. It will have powers for evil as well as good. Before long the charlatan will be exploiting its wonderful powers in the daily press at so much per line.

The investigations of this substance have only begun. Every week adds some new report to its wonders. It will not prove to be the panacea for all human ills—enough trial has been made to show this. It will have a specific limited field of action. First reports are sometimes flattering. Further trials must be made. But no new substance has been discovered during the history of the human race around which so much mystery clings as to this new element—radium. The principles of the conservation of energy, and the law of gravitation itself may need some changes in our statements of them, as a result of the properties found to reside in this particle of matter. It occupies almost the same place in physics that a biologic discovery would occupy in biology if it should apparently offer some serious objections to the generally accepted theory of the origin of species.

It is impossible to note in a subject like this, those to whom we are indebted for the work they have done; but acknowledgment is here made to Edgar L. Larkin, author of "Radiant Energy" for use made especially of his chapters on radiant energy and spectrum analysis; also to Prof. Oliver Lodge, Dr. S. G. Tracy, William J. Hammer on "Radium and Radioactive Substances," and John U. Lloyd.

# THE CONFLICTING CLAIMS OF GENERAL EDUCATION AND PROFESSIONAL EDUCATION.*

ARTHUR TWINING HADLEY.
PRESIDENT OF YALE UNIVERSITY.
NEW HAVEN, CONN.

For the last fifty years there has been a tendency to increase the length of time devoted to professional training. This tendency has not been confined to medicine or law, or to the so-called learned professions as a group. It is equally conspicuous in the various lines of engineering and technology. It is manifest in those departments of school work which fit the boy for trade or for commerce. In every sphere of human activity modern scientific studies have made their influence felt. In every sphere, therefore, the practitioner who is familiar with the methods and processes of his science—be it physiology or mathematics, physics or economics—has an advantage over his competitor who knows only those rules of practice which can be picked up in the office or the shop.

But there are some respects in which this tendency has been more strongly felt in medicine than in any other calling, for a physician needs to be trained in more kinds of scientific study than almost any other man in the world. He must know something of physics and much of chemistry; he must know something of morphology and much of physiology. Each advance in any of these sciences increases the importance of the preliminary training which is essential to the successful practice of the arts of medicine and of surgery and the length of time which must be devoted thereto. If we add to the time thus consumed in the study of science the time which is involved in learning the practice of those arts—whether in the higher classes of the medical school or in the hospital experience which should follow—the period of technical training becomes so long that it is a burden to all men, and an almost insupportable burden to those who are poor. And if, in addition to this, we urge that the student of medicine should previously have completed a college course of the old type, we seem to postpone indefinitely his chance to become an independent practitioner and to have the comforts of a home and a family of his own.

Under such circumstances there arises an almost inevitable conflict between the claims of general education, as represented by the college, and the claims of technical education, as represented by the medical school, and in less degree also by schools of law, or theology or engineering. This conflict involves so many different issues and deals with matters of so much perplexity that I have felt some hesitation in offering an address on this subject which shall set forth the claims of the college. But from all that I have heard of this body, I believe that the very difficulties of the case will cause its members to welcome a presentation of a side of the argument different from that which is perhaps more habitually brought before their consideration.

As a first step in our analysis of the problem, let us try to get clearly before our minds exactly what we are talking about. What is the *difference* between general education and technical education? What is the distinction between the college and the professional school or group of professional schools? Most people would say that it was a difference in the nature of the studies pursued. Fifty years ago that would have been largely true. To-day it is not true. Fifty years ago the college taught a curriculum of classics and mathematics, with some metaphysics and a little very elementary science and history, which was supposed to give a foundation of general knowledge for all men; while the professional schools, whether of law or medicine or theology, were occupied with teaching the details of practice—to expound a text, to collect a note, or to write a prescription more or less suited to the occasion in hand. To-day things have changed at both ends. The professional schools no longer occupy themselves solely or chiefly with teaching the practice of their several arts, but lay at least equal stress on the training in the sciences which are at the foundation of those arts. The colleges no longer compel their men to go through a certain curriculum; but they offer a choice of courses suitable to the tastes and abilities of different individuals, from which each can choose that which best meets his wants. Within the limits of a college course the man who would be an engineer can gain an excellent knowledge of mechanics; he who would become a lawyer can learn the fundamental elements of legal theory; while he whose tastes lead him to the study of medicine can master not only the principles but the practice of chemistry, and can familiarize himself with anatomy and physiology and physics, and all those various sciences which form the foundation of successful medical study.

---

* Address before the Medical Society of the State of New York, at Albany, Jan. 26, 1904.

What, then, is the difference between a college and a group of professional schools? What, then, determines whether we should advise the student to obtain these acquirements in the one institution or in the other?

The difference, I take it, is not in the studies themselves, but in the surroundings under which they are pursued. The distinction is not in the things taught, but in the ethical atmosphere in which they are learned. The college student pursues his investigations amid a set of associations which bring him into contact with non-professional life on as many sides as possible. The student in the professional school, on the other hand, is in an atmosphere which reduces these outside influences to a minimum and encourages him to narrow his efforts on the work immediately in hand. The college course gives a man breadth of sympathy; but with all except the best men, this breadth is accompanied by a sacrifice of intensity of application. The professional course secures the intensity, but with a corresponding danger of sacrifice of breadth. Which of these alternatives shall we choose? Which of these ends shall we pursue to the comparative disregard of the other?

The tendency of late years has been to choose the second alternative—to regard intensity of application as the vitally important thing to be secured, and to look with distrust, if not with absolute dislike, on scientific requirements which have been obtained in the broader but less exacting atmosphere of collegiate study. Indeed, this attitude has in some instances gone beyond mere distrust or dislike. A man who has acquired his chemistry or his anatomy outside of the medical school is liable to a summary rejection of his claim that this knowledge has in any wise advanced him toward the practice of his profession. Speaking broadly, a student's class rating in our medical schools depends not on his amount of knowledge, but on the time that he has spent in some medical school in acquiring that knowledge—the duration of the period during which he has breathed the professional atmosphere. We do not go so far as the legal profession does in England, where admission to the bar is based on the number of dinners that a man has eaten at a certain place; but the difference is one of degree rather than of kind.

Now it is easy to see the reasons which have led to the adoption of this general policy. We want to have our professional men trained in habits of intense application. This will save their time, will make their work more efficient, and will fit them for the practice of their profession more speedily than would be possible in any other way. What I wish to point out is that this gain is attended with certain serious dangers of loss to the student himself, to the cause of scientific progress, and to the influence of the medical profession as a whole; and that any consideration of the subject which looks only at the gain and fails to notice the loss is an imperfect and somewhat dangerous one.

The first of these dangers is that of commercialism. To this danger the student who does all his scientific study in an exclusively professional atmosphere is often very seriously exposed. A professional school is filled with men who are anxious to make a living, and who look on their scientific study as a means of enabling them to make a living better than they could without it. In fact, the special intensity of their effort in the early years of professional study is largely due to this commercial motive. There are some men to whom this will do no particular harm. There are others to whom it does very great harm indeed. With such men science, instead of being regarded in her proper light, as an agent of service to society, becomes a mere handmaiden of business. A man who looks at medicine in this way will probably make more money than if he looked at it in any other way; but I am sure that the members of this audience would regard this monetary standard as a very ignoble measure of the aims of the medical profession, and would deprecate any change in the system of education which would give increased prominence to this element of success in the mind of the young man of twenty who is beginning his scientific studies and forming his scientific ideals.

The evil effect of such a perversion of standards does not stop short with the individual student. It is bound to show itself in the methods of the profession as a whole. It will result in an undue exaltation of those elements of study and practice which form the basis for triumphs of technical skill. It is, perhaps, presumptuous for a layman to form a judgment on matters like this; and yet I can not forbear saying that the temper of many of the students and of some of the instructors in our medical schools is to-day rather unfavorable to the study of physiology. Anatomy, which is in many ways an exact science already highly developed, they pursue to the utmost, and make it a basis of successful surgery. Certain parts of pathology, in like manner, are made a basis of successful medical practice; but general physiology, by comparison, at least, is neglected. In such schools —and there are many of them—the students are led to use the results of the past to cure the individuals who are afflicted with certain definite diseases; but they are not in corresponding degree led to make scientific progress in those fields which to-day are difficult and doubtful, and give no assurance of commercial return to the investigator, but whose very doubt and difficulty make investigation more necessary and give greatest possibility of service to future generations.

And, apart from its direct effect on the physician himself, this separation of the scientific studies of the medical profession from those of other men has, I think, an indirect effect adverse to the political and moral influence of that profession in the community as a whole. It tends in some degree to make the physicians a guild or trades union, apart from the rest of society. The old-fashioned country practitioner, who had learned nearly all his medicine from contact with his fellow-men, was extremely defective in his scientific training; but he was a power in the community, and knew how to influence the conduct and life of that community. His successor to-day knows more of science, but he does not always know as well how to make that scientific knowledge a stimulus to those about him.

We can, perhaps, understand the real nature of the change better if we look outside of the medical profession and see how a similar change has taken place in the aims of the lawyer in the progress of the law and in the influence of the legal profession in the community. The lawyers of to-day are far better trained in the theory of their profession than was the case a century or a half century ago. They make fewer mistakes. They know more accurately how to adapt means to ends. But there has been an increased narrowing of the standards of success, which gives us more men with large incomes, but fewer Lincolns and Websters and Calhouns. There is an increased ability to take advantage of technical details in advising a client to avoid a lawsuit, but a diminished readiness to adapt the law to new conditions, commercial and social, in the way that the English judges of 1700 or the American judges of 1800 were ready to adapt it. There is, in short, a separation of interests between the legal profession and the community in which the lawyer lives, which stands in the way of the rendering of that public service which the profession should be competent to perform.

Is there any remedy for all this? I believe that there is, and that it lies in the direction of encouraging men to do the preliminary work of preparation for their several callings while they are yet in the broader atmosphere of the college, rather than in the narrower atmosphere of the professional schools. Some sacrifice of intensity of application this doubtless will involve; but I believe that any loss from this cause will be more than compensated by the increased gain in sympathy and enjoyment, in the spirit of progress and in the power of using such professional work for the benefit of a man's fellows, which will accrue from this change. I would not abate one jot of the strictness of our requirement of scientific knowledge as a preliminary in professional study; but I would welcome that knowledge, no matter where it was acquired. I would hold that if a man really had the necessary training in chemistry or anatomy, he would make a better physician instead of a worse one if he had obtained it outside of the limits of the professional school. Instead of discouraging men from beginning their scientific studies before they enter a professional school—which is the net result of our present somewhat exclusive policy—I would stimulate such study in the colleges, giving fair recognition to its results. I would encourage a man to begin his scientific specialization at as early a period as possible and to defer his ethical specialization until as late a period as possible. The sooner a man's brain begins to turn to his lifework the better; but the later a man's horizon tends to be narrowed to the sphere of his lifework the better also.

I believe, therefore, that the true policy is not a shortening of the college course and an attempt to make it a time of intellectual eclecticism, if not of intellectual dissipation; but an inclusion within that college course of all the scientific studies which it can be made to contain, and the fullest recognition by our various professions and professional schools of the results of such study when obtained in the college atmosphere. I believe that in this way we can best solve the problem of training men for the duties of their several professions, without untraining them for the wider duties of scientific progress and of American citizenship. I believe that in this age, more than in all others, we need to emphasize the importance of those conditions in education which make for catholicity of sympathy, for wide acquaintance with all kinds of men, and for broad range of vision, both present and future. I plead not for any lowering of professional standards or for any lessening of intensity of requirements; but for the recognition of the great fact that our engineers and our lawyers, our ministers and our physicians, must be men first and technologists afterwards—and that any true system of professional education should find a place for helping men to broaden their mental and moral horizon, even while they are learning to concentrate their vision on those special lines of human activity with whose investigation they are charged.

**The Cultivation of Medicinal Plants.**—The *American Journal of Pharmacy* for December contains an article by Dr. Kraemer, the editor, on "The Conservation and Cultivation of Medicinal Plants," in which he predicts an early extermination of the principal medicinal plants of this country unless measures are taken to protect and to cultivate them. Certain well-known plants, as spigelia, serpentaria and senega, are already becoming scarce, whereas in Linne's time they were found in abundance in Maryland and other Atlantic states. It is well known that some plants have been improved by cultivation, and it is reasonably to be supposed that all can be when the peculiar requirements of each have been ascertained. Kraemer urges a study of these plants in their natural surroundings that they may be successfully cultivated and conserved. Many of the medicinal plants now in use are being cultivated in this country. It is stated that 40,000,000 pounds of peppermint are produced annually near Kalamazoo, Mich. Castor beans, from which castor oil is obtained, are raised in the west and middle states. Valerian is produced in Vermont. *Digitalis purpurea*, *Atropa belladonna*, *Sanguinaria canadensis*, *Cimicifuga racemosa* and many equally valuable plants have been raised experimentally in this country and, in Kraemer's opinion, could be grown successfully with the proper cultivation. A number of native medicinal plants which still grow here in abundance are named. The more common ones mentioned are couch grass (*Agropyrum repens*), marshmallow (*Althæa officinalis*), stramonium leaf and seed (*Datura stramonium*), grindelia (*Grindelia robusta*), hydrastis (*Hydrastis canadensis*), mandrake (*Podophyllum pelatum*), and American hellebore (*Veratrum viride*). Kraemer urges the further cultivation of certain plants which have been introduced into this country and grown here to some extent, such as senna (*Cassia acutifolia*), colocynth (*Citrellus colocynthis*), gentian (*Gentiana lutea*), poppy (*Papavera somniferum*), etc. He believes that three-fourths of all medicinal plants are grown either wild or in cultivation in this country, and that fully one-half of the remaining fourth could be successfully raised here. Americans must realize the necessity of protecting their forests and plants, and must consider their care and preservation a duty both to themselves and to future generations.

## THE NEED OF A UNIFORM STANDARD FOR DEPARTMENTS OF HEALTH.

A list of questions was sent recently to the departments of health of various representative American cities. These inquiries related to the reporting and isolation of contagious diseases and to subsequent disinfection. The answers received from sixteen cities reveal a quite surprising divergence of view as to what ailments are included in the class of contagious or infectious diseases and as to what are considered adequate measures for protecting the community. In what follows it will be understood that no exact statements are intended as to the procedure of all American cities. The instances mentioned are given simply to show the wide divergence on essential points found among certain typical cities. The answers received from these cities were necessarily brief, and access to the various sanitary codes was practicable in only a few cases, so that in some instances only general statements concerning the methods can be made. In others the details can be given more fully.

All the cities answering require the reporting of smallpox, diphtheria and scarlet fever, but there uniformity ceases. Baltimore, Philadelphia, St. Louis, Providence and Rochester are not content with the reporting of diphtheria alone, but very properly insist on the reporting of all cases of membranous croup. Inasmuch as the majority of these cases are due to infection by the Klebs-Loeffler bacillus, it is generally recognized that the two diseases are practically identical, yet so long as the reporting of membranous croup is not required, it affords an easy way of relieving the family from the annoyance of placarding and isolation. Baltimore, Chicago and Philadelphia are the only cities in the list requiring specifically the reporting of varioloid, yet there is the same reason for reporting varioloid as for reporting membranous croup. Philadelphia, indeed, makes a special point of reporting chicken-pox, and claims that several cases of smallpox have been thus discovered. Other cities which require chicken-pox to be reported are Baltimore, St. Louis, San Francisco, Salt Lake City and Rochester. Measles and whooping cough are communicable diseases, yet among the cities answering only Baltimore, Salt Lake City and St. Louis mention both, while San Francisco and Providence mention measles only. Cholera and typhoid fever are diseases which, though only indirectly communicable, are peculiarly amenable to control by sanitary measures, and it would, therefore, seem highly advisable that these diseases should be included in the list for compulsory reporting. It is easy to understand why cholera is omitted, as it is so long since there has been an alarming outbreak, but typhoid is endemic in many of our large cities, and there are few diseases which departments of health, wherever they are free to exercise their legitimate functions, could so successfully combat. Chicago, Baltimore, San Francisco, Providence, Salt Lake City, Philadelphia, St. Louis and Rochester specifically mention that the reporting of typhoid is required.

It is easy to see why yellow fever should be listed as it is in seaport towns and not in northern inland cities, but it is not easy to understand the varying attitude toward other diseases, notably epidemic cerebrospinal meningitis, erysipelas and puerperal fever. Philadelphia, Salt Lake City and St. Louis require the first disease to be reported, and St. Louis and Salt Lake City go so far as to insist on placarding, although St. Louis does not placard measles or chicken-pox. St. Louis and Rochester seem to be the only ones which require the reporting of erysipelas and puerperal fever. Philadelphia stands alone in regarding relapsing fever as a dangerous, communicable disease which must be reported. It is singular, in view of the fact that cases of leprosy occur every now and then throughout the country, that Philadelphia is apparently the only city requiring it to be reported. When we remember the recent conflict between the Federal and local authorities as to the existence of bubonic plague along the Pacific coast, it is noteworthy that San Francisco does not mention this disease among those which must be reported to the health department, although Salt Lake City places it on the list.

There is compulsory reporting of tuberculosis in New York, Boston, San Francisco, Baltimore, Rochester, Providence, Atlanta and Louisville. In the reporting of tuberculosis, departments of health often contend with opposition on the part of the medical profession, and the physician in turn must contend with strong opposition on the part of his patients and their families.

The requirements of the different departments as to placarding and isolation vary widely. In the case of Baltimore, placarding and absolute isolation are apparently required for all the severer infectious diseases and also for whooping cough, mumps, typhoid fever, consumption and chicken-pox. Des Moines, New Haven and Louisville assert that they enforce placarding and complete isolation for "all contagious diseases." Chicago's sanitary code requires placarding for smallpox, scarlet fever or any "contagious, infectious, pestilential or epidemic disease." The code of Salt Lake City is extremely strict, and the printed rules require not only the placarding for such a disease as epidemic cerebrospinal meningitis, but make it unlawful for any person in the house with such a case to leave the house without a written permit from the board of health. Of course, such over-strict requirements are liable to defeat themselves. On the other hand, certain cities require only the placarding of smallpox, diphtheria and scarlet fever. Such are Boston, Detroit, Minneapolis, Atlanta, St. Paul and Providence. Rochester adds measles.

The degree of isolation apparently required varies widely. As instances may be given the Salt Lake City rule quoted above, which applies to all contagious diseases, and the following answer given by the Providence board, applying to all reportable diseases: "Not so strict as formerly. Children in family kept out of school and advised to stay on the premises. Other children in house usually allowed to go to school. Wage earners usually allowed to go to work." We suspect that whatever the requirements by official rules may be, the Rochester answer comes near representing the general practice. It is as follows: "We do not require isolation from other members of the family, because we believe it can not be enforced in practice."

There is room for difference of opinion regarding the value of placarding in the prevention of the spread of communicable diseases, but if it is, as seems to be the case, generally accepted as a valuable procedure, then it would certainly seem possible in the present state of medical science to arrive at a more uniform standard of application than is shown by these answers. In practice, some towns having the most stringent rules leave much to the discretion of officers. Philadelphia and Chicago, for instance, leave placarding to the discretion of inspectors and attending physicians, although the Chicago code especially is most sweeping and mandatory on this point.

As a usual thing, either sulphur or formaldehyd, or both, are stated to be the disinfecting agents used, but even here a striking diversity of opinion is shown. One reply states that "the work of the department in disinfection with formaldehyd gas has been exceedingly successful." Another reply says: "All forms of formaldehyd disinfection are a delusion and a snare."

There are, of course, still many obscure points in the etiology of contagious diseases, but the mode of transmission of most of these diseases is fairly well understood. On the other hand, as a matter of administration, it is true that many non-medical considerations affect the degree to which the sanitary code is enforced in each city. If the code gives the department of health strict rules and large discretionary powers, the enforcement is necessarily difficult and obstructed by considerations outside of those purely medical, while, if the rules are very lax, the enforcement will hardly be vigorous.

We would respectfully suggest that no subject could more fitly engage the attention of the Section on Hygiene and Sanitary Science of the American Medical Association than this of securing a scientific and practicable standard for the control of communicable diseases by municipal departments of health.

## THE INFLUENCE OF SODIUM CHLORID AND DECHLORIDATION ON CARDIAC AND OTHER DROPSIES.

The influence of sodium chlorid on the dropsies attending various forms of nephritis was brought to the attention of the medical world in a paper by F. Widal and A. Javal,[1] which has been noticed[2] in these columns. Since then the study of the fate of sodium chlorid in the body and the influence of that salt on dropsies and edemas has been diligently pursued by the French clinicians. According to the investigations of R. Marie,[3] it appears that when sodium chlorid is not eliminated it does not remain in the blood, but passes into the interstitial circulation, where it reaches a fixed percentage, usually about six grams to the thousand. When the retention is increased, the strength of the plasma does not change, but the tissues become more hydrated, and when the retention becomes very marked, the interstitial fluid becomes greatly increased and edema results. All the retained chlorid is not contained in the interstitial plasma, however, and Marie believes there are two stages in the retention: (1) that of fixed chlorid, in which the chlorids are contained in the tissues or organs, and (2) that of free or circulating chlorid, in which the chlorids are in the interstitial circulation. The variations of the latter chlorid are indicated by variations in the weight of the patient. It would seem, then, that depriving the edematous patient of chlorids would result in a diminution of his edema. The work of Widal and Javal seems to confirm this theory, insofar as the edema of nephritis is concerned. It has also been shown that dechloridation has an influence on the amount of albumin in the urine in these cases. Hallion and Carrion[4] suggest that the influence of a chlorid-free diet on albuminuria may be accounted for (1) by a modification of the osmotic tension of the glomerular secretion, as advanced by Castaigne and Rathery,[5] and (2) by a modification of the albumin of the blood, due to the proportion of chlorids which the organism contains. These authors object to the former theory and approve of the latter.

While dechloridation has been found of decided benefit in cases of edema complicating nephritis, no such striking results have been observed in cases of edema complicating cardiac disease. Widal, Froin and Digne[6] have studied the effects of dechloridation and of the administration of chlorids in nine patients suffering from cardiac affections, with more or less pronounced edema of the extremities. They have found that in three of these patients, in spite of increasing alimentary chloridation, the edema and the body weight diminished progressively. On the other hand, three other patients increased in weight when given ten grams of sodium chlorid daily with their diet. Again, in four patients dechloridation had no influence on the weight, or at most produced slight reductions only. In spite of these results, the authors conclude that a certain advantage is to be gained in cardiacs by prescribing a diet composed of meat, potatoes, butter and bread, all without salt, because such diet seems to prevent the increase of an existing edema. Vaquez and Laubry,[6] on the other hand, have satisfied themselves that a diet rich in sodium chlorid is dangerous for patients with cardiac disease because it renders them more liable to general and local disorders, such as dyspnea, insomnia, vomiting and albuminuria. Bergé[7] reports a case of arteriosclerotic nephritis with aortic insufficiency, which is somewhat illustrative of the last statement. Bergé had given his patient subcutaneous injections of normal saline solution once a week for eighteen weeks without harmful effect. Some months later a second series of injections was begun, and after the third administration of 200 c.c., the patient, developed an attack of pulmonary edema. Vaquez and Laubry believe that dechloridation of the diet is useless when a cardiac lesion is compensated; but when there is transitory asystole this form of diet is a useful transition between an absolute milk diet and a normal diet.

Chauffard[6] put a patient with atrophic cirrhosis of the liver, ascites and edema of the lower extremities, scrotum and lumbar region on a dechlorized diet. While the ascites was not benefited, the edema disappeared after paracentesis abdominis and did not reappear, although the ascites reaccumulated more rapidly than it had before when ten grams of sodium chlorid were administered daily with the food. Chauffard believes that if the dechloridation of the diet does such a condition no positive good, the administration of large quantities of sodium chlorid may do positive harm.

It would seem from these recorded experiences that a chlorid-free diet may prove of value in the hands of the internist in certain cases of cardiac disease complicated with dropsy; if not as a curative measure, at least as a prophylactic method directed against some of the more serious terminal accidents of this disease.

## LYMPHOTOXEMIA, THE STATUS LYMPHATICUS AND ALLIED DISORDERS.

Observations of a relationship between spontaneous sudden death and enlargement of the thymus, extended by Grawitz, Paltauf and others to enlargement of other lymphoid tissues as well, have demonstrated a condition which, although still shrouded in obscurity, has acquired a distinct name and fairly definite anatomy. Death is so sudden in some instances that the only symptoms observed are associated with cardiac or respiratory failure; in others death is practically instantaneous and observation of symptoms is impossible.

Although chiefly occurring in children with rickets, infantile eclampsia, tetany and the so-called thymic asthma, the anatomic evidences of lymphatism or status lymphaticus have been found in adults in exophthalmic goiter, idiopathic epilepsy, and in cases where sudden death has followed trivial physical stimuli. Numerous observations have concerned death from anesthesia in both adults and children and from the use of all forms of general anesthetics. That death in these cases may result from or be favored by the enlarged thymus, seems likely from a few observations: The trachea has been found with its lumen all but obliterated; in another instance it displayed a marked "saber-sheath" malformation; in a report by Kohn, the aorta was found enveloped by the overgrown thymus and the heart both hypertrophied and dilated; in some instances the fatal ending has been attributed to pressure on the vagi. The anatomic position of the thymus has naturally suggested its causative connection with dyspnea and laryngeal spasms, seen especially in infants, but the failure to find any notable constant hyperplasia has gradually led to the abandonment of this view.

The recent suggestion by Blumer[1] that death in cases of lymphatism is due to a cytotoxin, possesses many features of interest. He was led to this assumption by finding in the 9 cases studied changes very similar to those observed in animals injected with alien serum containing—in the nomenclature of the Ehrlich theory of immunity—amboceptors specific for various lymphoid tissues. If the increased production of lymphoid tissue in the pharyngeal, thoracic and abdominal lymph glands and in the intestine, spleen and thymus, takes place from the action of a toxin, and is, therefore, in a measure an adaptive process and in accord with Weigert's law of degeneration and proliferation, the sudden and hitherto unexplained spontaneous death in these cases may be due to changes caused elsewhere in other tissues by the toxin.

There is every reason to believe that molecular and chemical alterations may occur in disease for which we are at present unable to demonstrate corresponding morphologic changes. On the other hand, improved technic and an increasing thoroughness are constantly revealing structural modifications in diseases of the so-called "functional" type. That these cases of lymphatism will show on further research variations of structure explaining the abrupt and unexpected death, may be confidently expected. Some hint of this is afforded by the recent description by Peters[2] of the changes in tetany, a disease which may be but a symptom-complex of lymphatism or lymphotoxemia. He found, in 8 cases, an external hemorrhagic pachymeningitis of the spinal cord with inflammatory changes in the spinal ganglia and both motor and sensory roots. Details of the condition of the lymphoid organs and tissues in these cases of tetany are not described, and in the contribution by Blumer there is no mention of examination of the nervous system. During tetany, laryngeal spasms occur, and several of the infants examined by Peters exhibited such symptoms. Death occurred in one of the 8 suddenly during such an attack. The words of Ohlmacher, whose investigations established the occurrence of status lymphaticus in idiopathic grand mal, are worthy of repetition: "The tendency to bring to a common basis whose essential expression is the lymphatic constitution such obscure neuroses as tetany, eclampsia of infancy, laryngeal spasm and mors thymicum, can not be ignored." With the demonstration of changes characteristic of such diverse clinical phenomena, perhaps the necessity to distinguish some of them as separate diseases may disappear. The cytotoxins instrumental in causing hyperplasia of the lymphoid tissues in some forms of the status lymphaticus may be different from those operative in others; they may be bacteriogenic in one and of somatic origin in another. Estimation of the number and variety of the leucocytes in the circulating blood in diseases with which the lymphatic constitution is associated, is called for, and also of the lyt.c properties of the sera of these diseases for human leucocytes and lymphoid tissues. Indeed, the problems for research in these little known affections are, to a large degree, present also in the more familiar and kindred diseases—splenic anemia, leukemia (especially the acute form), Hodgkins' disease and multiple myelomas, since these also may be caused by the actions of toxins. Not the least needed is orderly and skillful examinations of the nervous system to determine if possible some explanation of their high mortality.

## AN OBJECTION TO SMOKELESS POWDER.

The object of many of the devices of warfare is to inflict the greatest damage to the enemy at the least cost to the other side, and smokeless powder is used to prevent concealing some portions of an opposing body. Attention has recently been called to an interesting aspect of the use of smokeless powder in naval warfare. In a target practice on a warship the wind blew the smoke and gases following the discharge of the guns back into the turret, incapacitating some of the gunners. The symptoms were convulsions, labored respiration, small and irregular pulse, feeble and tremulous heart action, headache, loss of consciousness, etc., and were ascribed in a large measure to the nitric and nitrous products created by the combustion. It, therefore, becomes in part a problem of ventilation. The ship crews must be protected from these fumes by proper devices. Torel,[1] writing on this subject, calls attention to the fact that under certain circumstances smokeless powder may be more of injury than of benefit to the ship crew using it.

## THE VALUE OF FRESH AIR.

If the present popular crusade against tuberculosis should fail in its purpose and "the great white plague" still continue to be more or less an important factor in the mortality, which we can not reduce beyond a certain definite point, it will have nevertheless worked out an immense amount of good in the mere fact that it has educated the people to the value of fresh air. In our northern climate, the changeable seasons and the necessity of guarding against extremes of temperature make us too apt to neglect ventilation both in public and private buildings. In the colder season Nature helps us to some extent against our will, as natural ventilation is then more active through entrances that can not be altogether obliterated by artificial means. Our buildings that are heated by grates, furnaces or stoves, when properly constructed and with air inlets suitably arranged, partly meet the conditions in supplying fresh oxygen to the inmates, though they are far short of sanatorium ideals. In our crowded city flats and tenements, however, the evil of vitiated atmosphere with its germs and other impurities forms one of the most serious of the disease-breeding factors in our midst. The tuberculosis crusade shows us that open windows even in our northern climate are not unendurable by invalids, to say nothing of healthy people, and that by coming back to more natural conditions we can escape many of the evils that have grown up about us. In the course of civilization man has gotten very far away from Nature—part of this of necessity and part from luxurious indulgence and the neglect of proper elements of health. We would be a hardier race if we coddled ourselves less, and the worst form of coddling from which we suffer is in our overheated and ill-ventilated apartments. Steam and hot-water heated flats, with storm windows and rubber-stripped doorways, are direct possibilities of lung and other infection. The awakening of the people to this fact, as well as to the dangers of crowded assembly rooms, street cars and other conveyances where fresh air is a dreaded and carefully avoided intruder, is an excellent thing.

## SUPRARENAL GRAFTING.

The hopelessness of Addison's disease makes of great interest any procedure that may be suggested for its relief. Some years ago Oesterreich, Professor Virchow's assistant at Berlin, reported a case in which the recognition of characteristic pigmentation, with lowered blood pressure, led to a suspicion of incipient Addison's disease, and operation with the removal of some portions of the suprarenals undergoing tuberculous degeneration was followed by relief. The success in this case, however, must be looked on as a happy accident rather than as a precedent to be followed. The difficulties in making a positive diagnosis of incipient Addison's disease are so great and the operation so grave that, except under the most favorable circumstances, a surgeon would hesitate to operate. A suggestion was made at the last meeting of the Society for Experimental Biology and Medicine,[1] which calls attention to the possibility of relief at more advanced stages of the disease when diagnosis has become more certain. Dr. Meltzer presented a case in which one suprarenal was removed and grafted into an incision in the corresponding kidney. When the other suprarenal was removed entirely, eighty-six days later, the animal survived and was apparently normal for twenty-one days, after which it was killed for examination. It is not surprising to find that the suprarenal may continue to live in the midst of kidney tissue, as portions of suprarenals are not infrequently found in the cortex of the kidney and are sometimes the source of malignant tumors—the so-called *hypernephroma*, which is usually fatal. It would seem, therefore, that this suggestive investigation might very well prove the basis for a surgical therapeutic measure that would at least prolong the life of some of our hopeless cases of Addison's disease. In animals, at least, the medullar portion of the grafted suprarenal seems to persist very well and to obtain a good blood supply.

## THE REMOTE EFFECTS OF HEAD INJURIES.

It has long been recognized that injuries to the head, generally with but sometimes without fracture, may be responsible for brain abscesses appearing weeks, months or even years after the injury. The rôle of such injuries in the production of neuroses and psychoses has been universally recognized and in some quarters greatly exaggerated. The physician who is not in touch with modern psychiatry is often too willing to assure the relatives of the insane patient of the absence of inherited predisposition and to place the blame on some injury that no one had thought of for years. It is still unsettled whether injuries to the head can cause brain tumors, but a history of trauma is obtained in a small percentage of cases, particularly of sarcoma and glioma. Another post-traumatic affection has created considerable controversy for some years. In 1891 Bollinger first called attention to the occurrence of cerebral hemorrhage weeks or months after a head injury. Recently Stadelmann[1] has contributed several convincing cases, and Harbitz[2] of Christiania has reviewed the whole subject in a lucid manner. As an instance of these so-called *"traumatische Spätapoplexien"* one of Stadelmann's cases may be cited. A working man, 29 years old, received a blow in the right parietal region which rendered him momentarily unconscious, but he was able to return to work in a few days. Four weeks later he was suddenly taken with convulsions, commencing in the left arm, and became unconscious. He died six days later, or thirty-four days after the injury. The autopsy revealed clotted blood in the leptomeninx of the right fossa Sylvii, with a small amount of softened brain substance underneath, and a clot the size of a pigeon's egg deep down in the right posterior central convolution; the surrounding brain substance was soft and edematous. There was also a focus of softening containing blood clots in the left frontal lobe. The course of events is supposed to be as follows: Trauma causes capillary hemorrhages, frequently surrounded by minute foci of softening, generally located in the surface of the brain beneath the contused part, but frequently also deep down around the ventricles, or in the portion of the brain diametrically opposite the injured portion. The changes produce a local circulatory disturbance causing edema, and this, together with the accompanying softening, causes a diminution in the pressure normally exerted from without on the vessel wall, and rupture is the result, occurring either spontaneously or from some trivial cause, such as sneezing, laughing, a heavy meal or emotion. Naturally in a given case one must be extremely cautious in deciding a hemorrhage to be of this kind. Stadelmann formulated the following conditions: 1. The patient must formerly have been in good health, not syphilitic, alcoholic, nephritic, or the victim of heart disease or arteriosclerosis. 2. The trauma must have been considerable, but need not necessarily have caused loss of consciousness. 3. The symptoms of the vascular and cerebral changes must be of distinct evolution and come on within a reasonable time. If years have elapsed, it will be practically impossible to establish a connection. The subject is worthy of attention, particularly on account of its obvious medicolegal importance. It is highly desirable that all such cases should come to autopsy, and a careful and critical comparison be made between the clinical and postmortem findings.

## LIFE-INSURANCE REJECTIONS.

A western contemporary[1] has protested with some vehemence against the custom among life insurance companies of exchanging lists of rejected applicants. The editorial refers to the condition as being "simply intolerable and outrageous." With this view the opinion of the *St. Paul Medical Journal*[2] is distinctly at variance. This journal calls attention to the fact that this is a beneficent provision to protect policy holders from deterioration of the average risk. In other words, if such a custom did not exist, it would be far easier than it now is, for persons who have been rejected on good and sufficient reasons, to secure insurance in other companies by skillfully obscuring the defect in family history, personal history, or physical condition, as the case might be, which had been the cause of the rejection elsewhere. Every life-insurance examiner is familiar with the endeavor of rejected applicants to remove the grounds of their disability. It may be, as has been charged, that some insurance companies are satisfied to learn that the applicant has been rejected, and will then give him no further consideration. Reference is made to a man's being put on the "blacklist." Such a one is perhaps unable to secure insurance and yet lives to a ripe old age. MacPhail[3] has recently investigated a large number of rejected candidates, and finds their length of life but little below the average life of accepted applicants. He ascribes this fact to the applicant having been warned of his condition, he amends his habits, improves his hygiene and thereby lengthens his life, and perhaps even overcomes some serious physical defect. These facts are, of course, to be borne in mind by the insurance examiner. The system of exchanging lists of rejected applicants, however, if used as a safeguard and not as a blacklist, is to be commended, protecting, as it does, the policy holder from loss through unwise risks.

## Medical News.

### CALIFORNIA.

**New College Opens.**—With appropriate ceremonies the Oakland College of Medicine was formally opened January 8. Dr. Frank L. Adams delivered the address of welcome.

**Sanitarium Burned.**—The Pajaro Valley Sanitarium, Watsonville, was destroyed by fire January 9. The six patients in the institution were removed in safety. The loss is $30,000, partially covered by an insurance of $13,000.

**More Plague.**—Two deaths from plague occurred in San Francisco in January. In Case 111 death occurred on January 10, and the diagnosis was confirmed January 25; in Case 113 the patient died on January 13, and the diagnosis was confirmed on January 22. During 1903, 17 cases occurred, and in 1902, 41 cases.

**Personal.**—Dr. Dennis D. Crowley, Oakland, has been appointed surgeon-general of the state, with the rank of colonel, succeeding Dr. Winslow Anderson.——Dr. Thomas Ross, Sacramento, has been made consulting physician of the Southern Pacific Hospital in that city, and Dr. Andrew M. Henderson has been placed in charge of the hospital.——Dr. Weston O. Smith, Alameda, president of the local health board, has resigned.——Dr. James W. Jesse, Santa Rosa, has been appointed physician and health officer of Sonoma County.——Dr. Henry B. Bessac, Forbestown, has been elected physician of Butte County.

**Wholesale Changes.**—The new San Francisco Board of Health, January 9, by abolishing numerous positions and creating many new ones, thereby effected, it is said, a saving of about $10,000 a year in salaries. The medical changes are as follows: Vacancies declared—Health officer, Dr. Aloysius P. O'Brien; bacteriologist, Dr. Howard Morrow, and city physician, Dr. Joseph G. Morrissey. Positions created—Deputy health officer, Louis Levy; district health officers, Drs. John F. Dillon, Albert S. Adler, and Frank J. Tillman; city physicians, Drs. George P. Purlenky and Tullio A. Rattanzi; chief inspecting physician, Dr. William C. Hassler; inspecting physicians, Drs. G. W. Goodale, Walter Jackson, Cosmos A. Glover and William J. Walsh; bacteriologist, Dr. Frederick G. Canney, and medical chemist, Dr. August C. Bothe. Dr. Denis F. Ragan has been confirmed as health officer, and Dr. George F. Brackett, chief emergency physician.

### IDAHO.

**Hospital at Boise.**—St. Luke's Hospital at Boise is a modern hospital building, erected at a cost of $25,000. It has nearly 40 rooms, and is equipped with modern appliances.

**Albion Has Smallpox.**—Several cases of smallpox have appeared in Albion, one of which is in the dormitory of the state normal school. The town was immediately quarantined.

**Personal.**—Dr. Edward E. Maxey, Boise, secretary of the state medical society, has gone east for post-graduate study.——Dr. Isaac S. Collins, Lewiston, has resigned as physician of Nez Perces County, on account of ill-health, and Dr. John F. Hurlbut has been appointed in his stead.

**Idaho State Medical Society.**—At the annual meeting held in Boise the following officers were elected: Dr. Jesse L. Conant, Genesee, president; Dr. Robert L. Nourse, Hailey, vice-president, and Dr. Edward E. Maxey, Boise, secretary and treasurer. The next meeting will be held in Lewiston.

### ILLINOIS.

**Medicine-Man Fined.**—W. M. Portner, an alleged doctor of medicine, traveling with a medicine company, was fined $100 at Piper City for practicing medicine without a license.

**Smallpox Closes Schools and Churches.**—The town council and school board of Bloomington decided, February 2, to close the schools and churches indefinitely on account of the alarming spread of smallpox.

**A Healthful City.**—Evanston asserts that it is the healthiest city in America. In 1903 only 212 deaths occurred, a death rate of 10 per 1,000. Of the deaths, 28 were due to pneumonia, 26 to heart disease, and 22 to tuberculosis.

**East St. Louisians Must Not Spit.**—The city council of East St. Louis, on January 25, passed an ordinance prohibiting spitting on sidewalks, in public buildings, street cars and railway stations. A penalty varying from one to five dollars is provided for every violation.

**Old Physicians Honored.**—At the annual banquet of the Decatur Medical Society, January 26, Dr. William J. Chenoweth, who has been 50 years in practice, and Dr. Ira N. Barnes, who was graduated 41 years ago, were the guests of honor. Dr. Silas E. McClelland acted as toastmaster.

### Chicago.

**Hospitals Under Ban.**—The building commissioner has notified 13 hospitals that they must receive no new patients until certain specified changes, looking to safety in case of fire, have been made.

**Alexian Brothers' Hospital.**—During 1903 this hospital cared for 3,062 patients; 1,932 were discharged cured, 488 discharged improved, and 91 discharged unimproved. The deaths of the year numbered 333. Of these 126 were in dying condition when brought to the hospital.

**Deaths of the Week.**—During the week ended January 30, 549 deaths were reported, 32 more than for the previous week, and 37 less than for the corresponding week of 1903. Pneumonia led with 121 deaths; consumption caused 57; heart disease, 56; bronchitis, 40, and violence 37.

**Result of a Cold January.**—Notwithstanding that the mean temperature of the month has been five degrees below the normal, the department of health states that the death rate promises to be among the lowest on record. The average January rate since 1893 has been 16.32 per 1,000. For the month just closing it will be about 14. The lowest during the period was 13.69, in January, 1898; the highest, 20.91 in 1893. Last January, although milder than normal, the public health was affected by the coal famine, and the death rate was 16.07 per 1,000.

### IOWA.

**Communicable Diseases.**—During December, diphtheria was reported in 9 localities; scarlet fever in 39; measles in 2; whooping cough and chicken-pox each in one locality, and smallpox in 12 localities.

**Sixty Years in Practice.**—To celebrate his eighty-sixth birthday and the sixtieth anniversary of his entry into practice, Dr. Ben Selman, Bloomfield, entertained the physicians of the city at a turkey dinner, January 17.

**Unlicensed Osteopath Fined.**—It is reported from Taylor County that D. B. Roberts pleaded guilty to the charge of practicing osteopathy at Bedford without proper legal authority, and was fined $300 and costs. He was committed to jail in default of payment.

**Dedication of New Medical Building.**—The new building of the Medical Department of Drake University was dedicated January 29. Dr. D. S. Fairchild, dean, read a paper on "History of the Growth of Drake University College of Medicine and the Changes in the Methods of Medical Education During that Time"; Dr. G. H. Simmons, Chicago, on "Medical Education, Ideal and Practical"; Dr. D. C. Brockman, Ottumwa, Iowa, "Duties of the Medical School to the Profession and to the Public"; Hon. Nathan E. Coffin, Des Moines, "The Relation of the College of Medicine to the City"; and Mr. Hill M. Bell, president of the university, "Relation of the University to the Medical School." The building is a two-story structure with high basement, making it practically a three-story building. It will be used especially for the junior and senior class work; the work of the first two years will be carried on at the university.

### MARYLAND.

### Baltimore.

**Deaths of the Week.**—The deaths last week numbered 235, an annual death-rate of 21.24 per 1,000; consumption and pneumonia leading with 33 and 28 respectively.

**For Tuberculosis Sanitarium.**—Of the $25,000 needed to secure another $25,000 offered by a man of Baltimore for the building of a sanitarium in the Blue Ridge in connection with the Hospital for Consumptives, $14,000 has been raised by the Quarter Club, and from other sources.

**Halliburton Lectures.**—Dr. W. D. Halliburton, F.R.S., professor of physiology at King's College, London, lectured last week before the students of the University of Maryland and before those of Johns Hopkins. The subject of the former lecture was "The Proteids of Muscle and Nerve." He was the guest of Dr. John C. Hemmeter while in Baltimore.

**Tuberculosis Philanthropy.**—During his visit to the Tuberculosis exposition last week Mr. Henry Phipps of New York, well known for his philanthropy in this field, gave to the Johns Hopkins Hospital, through Dr. William Osler, for the purpose of establishing a separate out-patient department at the hospital, $20,000. It is said that he gave one-half this amount to the same institution a year ago. His gifts to the institution in Philadelphia, founded by him and bearing his name, are said to amount to several hundred thousands. In connection with the work at the Johns Hopkins Hospital, it may be mentioned that it has been carried on for several years through the generosity of two ladies of Baltimore. Cases have been visited in their homes and special directions given to the families as to the management of the disease. A library of tuberculosis has been started.

## MASSACHUSETTS.

**Hospital for East Boston.**—There is a bill before the legislature to appropriate $100,000 for the erection of a hospital for East Boston.

**Hospital Union Fund Concerts.**—During February the Hospital Music Fund Committee will give concerts at Adams Nervine Asylum, Cullis Consumptives' Home, Home for Aged Couples, Boston City Hospital, and the Massachusetts Infants' Asylum.

**Willard Hospital Report.**—The annual meeting of the Willard Hospital, Bedford, for the treatment of alcoholism and narcotic habits, reports 53 patients treated during the year. Considerable enlargements have been made in buildings and equipment during the year, but the demand for more is urgent.

**Hospital for Children.**—The thirty-fifth annual meeting of the Children's Hospital Corporation in Boston reported 1,519 patients treated in the wards last year, and 24,529 in the outpatient departments. Earnest efforts are being made for funds to replace the burned convalescent home in Wellesley and for the erection of a hospital with adequate facilities in common with the new Harvard Medical School.

**Dissemination of Infectious Diseases.**—The quarterly meeting of the Massachusetts Association of Boards of Health discussed the dissemination of infectious diseases, the paper being read by Dr. Theobald Smith, and the source, effect and prevention of an unhealthy milk supply, the paper being by Prof. Charles Harrington. The association also took vigorous action in protest against the passage of the antivivisection bill now before the legislature which would very greatly interfere with the work of local boards of health in their efforts to prevent disease.

**Extension of Councilman's Work.**—The work of Dr. William T. Councilman of Harvard Medical School in the cause of smallpox, which was presented last year, is to be supplemented by further studies in the Philippines. Two of his assistants, who have worked for some years on the subject, Drs. W. R. Brinckerhoff and E. E. Tyzzier, will leave soon for Manila. They will endeavor to determine the relations of these protozoa to others, and the mode of infection of man. Other tropical diseases may also be studied as encountered. But the special object of the fund which pays their expenses is to gain more complete knowledge of these germs, associated with variola and vaccinia.

## PENNSYLVANIA.

**Physician Injured.**—Dr. Edward M. Emrick, Shamokin, was struck by a train at that place, January 18, and sustained a fracture of the base of the skull.

**Hospital Openings.**—Mount Pleasant Memorial Hospital, presented to the town by the late Jacob Justice of Philadelphia, was formally opened January 22.——St. Joseph's Hospital, Southside, Pittsburg, will be opened April 1.

**Election.**—The Medical Society of Center County held its annual meeting in Bellefonte, January 12, and elected the following officers: President, Dr. Walter J. Kurtz, Howard; vice-presidents, Drs. Samuel G. Coons, Benore, and John Sebring, Jr., Bellefonte; secretary, Dr. Jared Y. Dale, Lemont, and treasurer, Dr. George F. Harris, Bellefonte.

### Philadelphia.

**Dinner to Dr. Hinsdale.**—On January 29 a farewell dinner was given to Dr. Guy Hinsdale by a number of his professional friends.

**Did Not Report Smallpox.**—Dr. William C. Hollopeter was fined $10.50 for failure to notify the bureau of health of a case of smallpox. He contended that he had notified the bureau by telephone.

**School Hygiene.**—Under the auspices of the board of education a number of lectures are to be given on school hygiene. Dr. S. Weir Mitchell will deliver the first lecture, entitled "Nervous Diseases, Their Causes and Effects."

**Portrait Presented.**—An oil painting of the late Dr. Thomas G. Morton was presented to the Pennsylvania Hospital by the Association of Resident Physicians of that institution, January 11. Dr. Morton was connected with the hospital in various capacities for more than 40 years.

**Personal.**—Dr. R. Bruce Burns has been superseded as president of the board of directors of the Frankford Hospital by Dr. B. Frank Walters.——Dr. Randle C. Rosenberger, associate in bacteriology in the Jefferson Medical College, has been appointed director of the bacteriologic laboratories of the Philadelphia Hospital.

**Baby Farmer Convicted.**—Herbert J. Stahl, proprietor of a "baby farm," tried for the death of an infant from alleged starvation, has been convicted of involuntary manslaughter. The maximum penalty, which is two years' imprisonment and $1,000 fine, was imposed. The commonwealth asked for a verdict of murder in the second degree.

**Bequests.**—By the will of the late Cordelia A. Brown $5,000 is bequeathed to the Methodist Hospital to endow a free bed in memory of William Brown, her husband.——Harriet Richards, who died recently, left $10,000 to be expended by the executor of her estate in establishing free beds in one or more of the Roman Catholic hospitals of the city.

**Medicolegal Election.**—At the annual meeting of the Medicolegal Society, held on January 26, the following officers were elected: President, Dr. J. Cardeen Cooper; vice-presidents, John R. Umstead, and Dr. Justus Sinexson; secretary, Dr. William T. Hamilton; treasurer, Dr. G. M. O. Peltz, and censors, J. H. Wolfe, and Drs. Wm. Ruoff and Edgar W. Tully.

**New Medical Inspectors.**—Thirty-seven medical inspectors have recently been added to the department of health. These were chosen from 250 applicants, who were required to pass a Civil Service examination. Dr. Andrew A. Cairns has been appointed chief medical inspector. Dr. Thomas J. Beatty was made assistant chief medical inspector, and Dr. J. Howard Taylor, for years chief medical inspector, assistant medical inspector.

**Health Report.**—The report to the bureau of health showed, for the week ended January 30, 65 new cases of smallpox; for the previous week, 106. Of typhoid fever for the corresponding periods there were 126 and 88 new cases, respectively. The water supply in many parts of the city is very turbid because of the recent heavy snow and rainfall, a condition, perhaps, accounting largely for the increased number of typhoid cases. Pneumonia continues to claim a large number of victims, the number of deaths from the cause the last week being 97.

## RHODE ISLAND.

**Tetanus Patient Convalescent.**—A case of tetanus has been under treatment for a month at the Newport Hospital, with antitoxin, and is reported convalescent.

**Contagious Diseases.**—During October and November 210 cases of diphtheria were reported, 121 cases of scarlet fever, 86 cases of typhoid fever, and 44 cases of measles.

**Treats Many Cases.**—The Rhode Island Hospital reports 4,150 cases treated in 1903, and the average daily number of patients in hospital was 232. This is a marked increase, 19 per cent. and 10 per cent. respectively over the previous year.

**November Mortality.**—During November 580 deaths occurred in the state. Of these 165 were from communicable diseases, including 74 from tuberculosis; 79 from genito-urinary disease; 64 each from nervous and circulatory diseases; 58 from diseases of children, and 28 from violence.

**Election.**—At a recent meeting of the Newport Medical Society the following officers were elected: President, Dr. Christopher F. Barker; vice-president, Dr. V. Mott Francis; secretary, Dr. Mary E. Baldwin; treasurer, Dr. Douglas P. A. Jacoby; librarian, Dr. William S. Sherman; curator, Dr. Harry J. Knapp; bacteriologist, Dr. Chas. W. Stewart; executive committee, Drs. V. Mott Francis, William S. Sherman, and S. Parker Cottrell, and censors, Drs. William S. Sherman, Douglas P. A. Jacoby and Stephen C. Powell.

## SOUTH DAKOTA.

**Will War on Quacks.**—The State Board of Medical Examiners is said to be about to take active steps to rid the state of the numerous irregulars who have been plying their trade unrestrained up to this time.

**Fire in Hospital.**—Fire in the basement of the Sioux Falls Hospital, January 1, necessitated the removal of the patients in a fierce snowstorm, but no casualties occurred, and the building was not seriously damaged.

**District Society Meeting.**—The meeting of the Eighth (Yankton) District Medical Society was held in Vermillion, December 29. Dr. Frithiof N. H. Gyllenhammar, Gayville, was elected president; Dr. Thomas Cruickshank, Vermillion, vice-president: Dr. James L. Stewart, Irene, secretary and treasurer; Dr.

Sherman G. Berry, Tyndall, censor, and Dr. William E. Moore, Tyndall, delegate to state society. The next meeting will be held in Tyndall.

## TENNESSEE.

**Physician's House Burns.**—The house of Dr. William T. Watson, Lexington, was recently burned. The loss was $4,000.

**College Opens.**—Tennessee Medical College, Knoxville, opened January 4 for the mid-winter term, with an increased attendance.

**Smallpox.**—Sevier County has thirty or more cases of the disease.——The epidemic at Morristown is thought to be at an end.——In Knox County 101 cases are reported.

**Personal.**—Dr. T. B. Peyton, Gallatin, has been elected health officer of Sumner County, vice Dr. Brown, resigned.——Dr. William G. Ewing has been elected chairman of the Nashville Board of Health, succeeding Dr. John R. Buist, and Dr. Larkin Smith has been re-elected health officer.

**Crusade Against Illegal Practitioners.**—The State Board of Medical Examiners is making an active campaign against illegal practitioners of medicine. Two "herb doctors" of Chattanooga have been bound over to the Criminal Court; one of the accused was discharged and one failed to appear. More warrants have been issued.

**Commencement.**—The commencement exercises of the medical department of the University of the South, Sewanee, were held January 21. Dr. John S. Cain. the dean, delivered an address on "Medical Ethics," and Vice-Chancellor Wiggins an address on "The Necessity of Education in the Profession." A class of 27 was graduated.

## TEXAS.

**Smallpox.**—Burgess reports 3 cases; Sour Lake about 50 cases; Granger, 10 cases; Marshall. 7 cases; Troupe, 25 cases, and Tyler several cases.

**Still Another Medical College.**—Bell's Medical College, Dallas, has been incorporated with a capital stock of $3,000, by Dr. Arthur C. Bell and others.

**Hospital Transferred.**—Dr. Charles M. Rosser, Dallas, has formally transferred the Good Samaritan Hospital in that city to the president of the board of directors of the Texas Baptist Memorial Sanitarium.

**Society Meetings.**—Coleman County Medical Society.—At the last meeting of the society the following officers were reelected: Dr. Charles M. Alexander, Coleman, president; Dr. J. D. McCann, vice-president; Dr. Thomas M. Hays, Santa Ana, secretary and treasurer; Dr. Newton Long, Santa Ana, delegate to state association, and Drs. Gabriel B. Beaumont, Coleman, J. M. Mathews, and Charles M. Alexander, Coleman, censors.

Smith County Medical Society.—This society met at Tyler, December 8; the charter issued by the state association was presented, and the following officers were elected: Dr. Irvin Pape, Tyler, president; Dr. J. Charles Smith, Starrville, vice-president; Dr. Albert E. Woldert, Tyler, secretary and treasurer, and Drs. Thomas J. Bell, Jasper D. Phillips and John Z. Ferrell, all of Tyler, censors. At the banquet which followed, Dr. Holman Taylor, Marshall, councilor for the Fifteenth District, presided as toastmaster.

## UTAH.

**Hospital at Salt Lake.**—A building permit has been issued for the Latter-Day Saints' Hospital, Salt Lake City, to cost $90,000.

**New Post Hospital.**—The quartermaster-general has asked Congress to appropriate $155,000 for the erection of a new post hospital at Fort Douglas.

**Smallpox Epidemic.**—Smallpox is said to be raging in Cache and Box Elder counties. In Cache County 77 cases have already been reported.——Smallpox is abating at Nephi, and the quarantine has been raised.

**Weber County Society Meeting.**—The Weber County Academy of Medicine met at Ogden, January 6, and elected Dr. John S. Gordon, president; Dr. John Driver, vice-president; Dr. Lyman Skeene, Jr., secretary; Dr. Samuel L. Brick, treasurer, and Dr. James M. Harris, librarian, all of Ogden.

**Personal.**—Dr. Frederick E. Straup, Bingham, has been suffering from an infected wound of the thumb, which necessitated a partial amputation.——Dr. John J. Steiner has been appointed health officer of Panguitch.——Dr. Theodore B. Beatty, Salt Lake City, secretary of the State Board of Health, has been appointed a member of the committee on smallpox under the auspices of the U. S. P. H. and M.-H. Service.

## VIRGINIA.

**Bequest.**—By the will of the late Robert S. Bosher, Richmond, $2,000 is devised to the Sheltering Arms Hospital.

**Honor Dr. McGuire.**—On January 7 the Medical College of Virginia and the University College of Medicine suspended operations, and the faculties and students attended the unveiling of the statue of Dr. Hunter McGuire.

**Gives Solarium.**—Mrs. Lewis H. Hyde of New York has given $3,000 to provide for the erection of a sun-parlor in the Winchester Memorial Hospital. It will be octagonal, two stories high, and built almost entirely of glass.

**Free Hospital Treatment for Indigent Virginians.**—A bill is proposed making an appropriation of $17,000 to the Medical College of Virginia. The present annual appropriation of $5,000 for general purposes is included and is to be expended as heretofore. The remaining $12,000 is to be set apart for the purpose of payments to the college at the rate of $1 a hospital day, which includes board, lodging, nursing, etc. All citizens of the state are entitled to receive treatment on proper proof of citizenship, necessity for treatment and pecuniary inability to pay for same.

## WEST VIRGINIA.

**New Hospital Opened.**—The Mountain States Hospital, recently erected by Dr. Charles S. Hoffman at Keyser, has been opened for the reception of patients.

**Will Build City Hospital.**—The executors of the estate of the late Dr. Andrew G. Clarke, Parkersburg, have turned over to the designated trustees $26,308.56, the amount of the bequest for a city hospital.

**Societies Meet.**—Marion County Medical Society.—At the second annual meeting held in Fairmont, December 30, Dr. Presley B. Ogden, Fairmont, was elected president; Dr. Albert L. Peters, Gray's Flats, vice-president; and Dr. Jesse A. Jamison, Fairmont, censor. Dr. James W. McDonald, Fairmont. was re-elected secretary, and Dr. William H. Sands, Fairmont, treasurer.

Marshall-Wetzel Bi-County Medical Society.—The following officers were elected at a meeting held in Moundsville, January 4: President, Dr. John C. McCullough, Moundsville: vice-president, Drs. J. F. Reger, Littleton, and James E. Cooper, Cameron; secretary, Dr. W. De Witt Stewart, Moundsville, and treasurer, Dr. John R. Davis, Moundsville.

**Visiting Staff Selected.**—The members of the visiting staff of the Huntington Hospital have apportioned their time of service as follows: January, June, November—Drs. Thomas J. Pritchard, Charles T. Taylor, Isaac R. LeSage and Thomas F. Stuart; February, July, December—Drs. Edward S. Buffington, Alexander C. Burns, William R. Cummings, Eastbank, and S. W. Hogsett; March, August—Drs. Robert E. Vickers, Edward E. Sample, Thomas E. W. Grover and W. D. Hicks; April, September—Drs. Henry A. Brandebury, George N. Waldeck, Archibald Crary, and H. C. Solter; May, October——Drs. Morgan Baker, John D. Myers, J. E. Rader, and Cassius C. Hogg; and oculists and aurists—Drs. Thomas W. Moore. J. H. Reynolds and John C. Geiger.

## WISCONSIN.

**Sanitarium Opens.**—The Waukesha Springs Sanitarium under the superintendency of Dr. Byron M. Caples, has opened.

**Removal to Capital.**—The State Board of Health has moved its offices from Milwaukee to Madison. Dr. Cornelius A. Harper, Madison, has been elected secretary, succeeding Dr. Uranus O. B. Wingate. Dr. William F. Whyte, Watertown, has been re-elected president.

**Would Muzzle Dogs.**—All Milwaukee dogs running at large are to be muzzled for six months, if the recommendation of the joint committee on judiciary and health be adopted by the city council. The proposed ordinance has the endorsement of the Milwaukee Medical Society.

**Will Prosecute Paradis Again.**—The State Board of Medical Examiners announces that, notwithstanding its defeat in the case against Joseph E. Paradis of Marinette, for practicing medicine without a license, it will make another attempt to prosecute him, as the adverse decision was due only to a technicality.

**Eyes and Ears To Be Examined.**—Investigations have demonstrated that 38 per cent. of the school children of the state are defective in vision or in hearing, or in both. The State Board of Health has, therefore, determined that, on entrance to the public schools, each pupil shall be examined, and the parents of those found defective in sight or hearing shall be notified, and the suggestion made that corrective measures be taken.

**Personal.**—Dr. Frank Garlock, Racine, has gone to Manila, P. I., to practice.——Dr. Hasso A. Meilike, Clintonville, has been appointed a member of the State Board of Health.——Dr. Thomas B. McIndoe, Rhinelander, has been reappointed a member of the State Board of Medical Examiners.——Dr. Charles S. Sheldon, Madison, has been re-elected secretary, and Dr. Sidney H. Hall, Ripon, treasurer, of the Wisconsin State Medical Society.

## GENERAL.

**Panama Physicians Preparing.**—The U. S. Public Health and Marine-Hospital Service is said to have begun actively to prepare for the Panama Canal campaign. Physicians are to receive special training, and, under the supervision of experts, will endeavor to prevent much of the sickness that is liable to occur among the workmen on the isthmus. The headquarters will be in a large hospital to be erected at Colon.

**The Committee on Medical Legislation** of the American Medical Association, it is announced by the Chairman, Dr. Charles A. L. Reed, will meet at the New Willard Hotel, Washington, D. C., at 11 a. m., Wednesday and Thursday, February 10 and 11, in conference with the National Auxiliary Legislative Committee, consisting of one representative from each state medical association and from each of the national medical services.

## CANADA.

**Personal.**—Dr T. J. Norman of Toronto has been appointed assistant superintendent of the Asylum for the Feeble-Minded at Orillia, Ontario, in succession to Dr. Mohr.——Dr. Charles A. Hodgett has been appointed secretary of the Ontario Board of Health, in succession to Dr. Peter H. Bryce.

**A University for British Columbia.**—The idea of the establishment of a university in British Columbia was put forward recently at a meeting of the Tourist Association of Victoria, and the citizens of that province will work assiduously for the institution. Its success will probably mean a medical school on the Pacific coast.

**Epidemic of Typhoid Fever in Montreal Improving.**—The typhoid fever situation, which has been causing considerable alarm in Montreal during the past six weeks, is now decidedly improving. In Westmount only one new case has been reported in several days. At St. Henri no new cases have been reported during the past week. Dr. Fleury of the Notre Dame Hospital, has found, on making an examination of the blood of some of the St. Henri patients, that some of the cases were not genuine typhoid as was supposed.

**Toronto Orthopedic Hospital.**—The fifth annual report of this hospital, just issued, shows the past official year to have been the most successful in its history. In the first year 172 patients were treated; in the second, 221; third, 255; fourth, 278; fifth, 353. There were 31 patients Sept. 30, 1902; admitted during the following year, 322; total treated, 353; discharged, 323; deaths, 1; patients remaining at end of year, 29. Of the 353 patients, 146 were under and 207 were over 14 years of age. The number of operations was 290.

**British Columbia Association for the Prevention of Consumption.**—This was established at a largely attended meeting held in Victoria, B. C., January 20, at which were present delegates from all parts of the province, as well as representatives of the dominion and provincial governments. Sir Henry Joly, lieutenant-governor of the province, was elected honorary president, and Dr. Proctor of Kamloops, secretary; Dr. C. J. Fagan of Victoria, treasurer, and on the committee of management, Dr. J. C. Davie of Victoria and Dr. R. E. Walker of New Westminster. The provincial government will be approached for a grant of $25,000.

**The Health of Victoria, B. C., During 1903.**—There were reported in Victoria during 1903, 66 cases of diphtheria, 6 deaths; scarlet fever, 117 cases, 2 deaths; other cases of infectious diseases were very few, with no deaths. Two cases of smallpox occurred, but prompt measures prevented the spread of the disease. The Lazaretto at D'Arcy Island has only two patients—both Chinese. Precautions are still being continued to prevent the introduction of the bubonic plague. Taking Victoria's population at 25,000, the average death rate per 1,000 for the past three years has been 11.57. The total number of deaths in Victoria during 1903 was 131.

## FOREIGN.

**Neurology in Asia and the South Sea.**—The professor of psychiatry at Munich, Emil Kraepelin, has just started on a long tour of investigation through eastern Asia and the southern Pacific to study nervous and mental disease as it occurs there and the conditions which influence it, especially its relation to alcoholism. Dr. Gudden will conduct the psychiatric clinic during his absence.

**Anticharlatan Congress.**—The first annual congress of the Anti-Charlatan Society of Germany was held at Berlin, January 14. Excellent addresses were made on the legal status of quacks, on proprietary medicines, etc. The attendance was not as large as anticipated. Reissig of Hamburg advocated the plan of educating the public in regard to quack practices by means of popularly written pamphlets.

**Fifth International Congress of Dermatology.**—Berlin will welcome this congress Sept. 12 to 17, 1904. Professor E. Lesser will preside, and Dr. O. Rosenthal is the general secretary. His address is Potsdamerstr. 122 g. Berlin W. The themes appointed for discussion are: "Cutaneous Affections in Case of Anomalies in Metabolism," "Syphilitic Affections of the Organs of Circulation," "Epitheliomata and Their Treatment," and "*Present Status of Leprosy (since the first leprosy congress of 1897)*," and "Present Status of Anesthetic Leprosy."

**Visit of Spanish Medical Students to Paris.**—A large number of Spanish students from Madrid, Valencia, Barcelona and other university centers, recently took a trip to Paris, where rooms had been engaged for them in the Latin quarter. They took their meals at the large Students' Co-operative Restaurant, which was founded and is managed by and for the students of the quarter at the minimum of expense. The Pasteur Institute, the hospitals and the clinics were the goal of the medical members of the party, and every facility was afforded them by the committee of Paris students appointed to receive the delegation. Great scientific zeal was displayed by the students during the few days of their visit.

**Electrotherapy in Disfavor at Lille, France.**—Professor Doumer of Lille has for several years had charge of a service of electrotherapy, which he established with the modest sum of $1,300 in 1892, this expense shared by the city and medical faculty. As this sum was inadequate he has supplied apparatus as needed, paying for it himself. From this modest service have issued a large number of important works on electrotherapy. Some have been published in the *Nord Médical*, of which he is one of the three founders, and others in the official bulletin of the French Société d'Electrothérapie et de Radiologie. He has treated an average of 480 patients annually, and his laboratory has been frequently sought by visiting foreigners. One of his latest publications is on the "Treatment of Mucomembranous Enterocolitis with the Continuous Current at High Strengths." The municipal authorities at Lille have recently summarily closed his service, alleging that it is not sufficiently frequented to pay for the room it occupies, but the true reason, the *Nord Médical* asserts, is to be found in Doumer's political opinions.

**The Source of Radium.**—Joachimsthal in Bohemia has long been famous for its silver and tin mines. The German word for dollar, "Thaler," is derived from its name, as the first silver dollars were made there. As the silver mines were worked out, the place declined until a new industry took its place, the making of the fashionable "uranium glass," which owes its tints to the uranium ore which is found there in abundance. The refuse is called pitchblende or pitch ore, and is a submetallic, pitchy, grayish or greenish-black opaque substance which was regarded as of no value. When Curie, a year ago, wrote to the president of the Vienna Academy of Sciences to ask his aid in procuring him a large quantity of this pitchblende, several tons were forwarded to him and no charge was made. At present the Joachimsthaler authorities are cherishing their pitchblende and will not sell it at any price, not knowing what they ought to charge for it, and perhaps fearing that the supply will give out. It takes ten tons of pitchblende to produce one gram of radium.

**French Legislation on Vaccination.**—Vaccination has not hitherto been compulsory in France, but the new law, to take effect April 7, 1904, requires every resident in France, native or foreign born, to be vaccinated during the first year of life and revaccinated at the eleventh and twenty-first years. An incident is related in a foreign exchange showing the inconveniences of the old plan. An epidemic of smallpox had broken out at Nice, and the local authorities vaccinated the inhabitants as a preventive measure, not using coercion. An Englishwoman, an Eddyite, preached an antivaccination crusade and prejudiced many persons against it. The authorities were at a loss what to do, and had about decided to compel the lady to leave town when she contracted smallpox herself and died. The disease did not develop, we are told, among any of the newly vaccinated subjects. Such incidents can not occur after the new law goes into effect, as, if persons are not willing to submit to vaccination, they will not be allowed to reside in France. Nowhere else in Europe is a triple vaccination required.

**The New German "Academies for Practical Medicine."**—The Prussian authorities are planning an institution in connection with the public hospital in cities, which is to afford graduate instruction and train physicians in specialties. The city of Düsseldorf is building a new public hospital, and arrangements are being made for the new "Akademie für praktische Medizin" to be connected with it. It will have facilities for instruction in internal medicine, surgery, obstetrics, infectious diseases and a fifth department devoted to pathologic anatomy, etc. There will be subdepartments for eye, nose, throat and ear work, for children's diseases, cutaneous and nervous affections, and treatment of accidents. Physicians who wish to take up a specialty will be installed as assistants in the special departments, and after serving a certain number of years will be given a certificate as to their proficiency in their specialty. The training of nurses for the sick is also another task of the academy, with the holding of free graduate courses for all physicians, and instruction of the public in matters of hygiene, but the principal purpose for which it is organized is to perfect the education of the graduates from the medical colleges who are not allowed to practice until they have served a year in some hospital or allied official institution.

## Correspondence.

### Price and Quality of Diphtheria Antitoxin.

PHILADELPHIA, Jan. 30, 1904.

*To the Editor:*—In your editorial of January 23, on the subject of "The Price of Diphtheria Antitoxin," you state: "Judging from the correspondence before us, and from the information which we have concerning the manufacture of antitoxin, we can not but believe that the prices of antitoxin have been and are higher than is necessary for a reasonable profit."

Appreciating the wrong impression that has been created by the sensational articles appearing in the lay press and by your statement relative to the price charged being unreasonable, and to give the reasons why we discontinued the lower potency of antitoxin, formerly known as "Standard," will you permit me to state the following facts:

During the past nine years we have been preparing antitoxin especially to meet the demand of American physicians. We offered at first three grades, known as "Standard," containing 100 units per c.c.; "Potent," containing 250 units per c.c.; "Extra Potent," containing 500 units per c.c. The demand gradually increasing and being principally for the higher potencies, we cut out the weakest strength entirely, and placed two potencies of serum on the market, known as "Standard," the potency of which was increased to 250 units per c.c.; and "Concentrated," 500 units per c.c. During the past two years the demand for the higher potency serum or "Concentrated" has largely increased, while the demand for the weaker serum has greatly diminished.

We date every package of antitoxin and exchange for a fresh supply any serum not used within the time specified on the label. Our experience proved that the physicians demanded the more concentrated product, and since we were compelled to exchange for this the greater portion of the lower-potency serum distributed, and since these exchanges added a large expense to the distribution and cost of antitoxin, we believed that by issuing but one strength—and that the higher potency, the returns would be largely controlled; that we would be issuing what physicians demanded, and that this saving of expense of exchanging unused serum would warrant a reduction in price. This is what we have done, and prices have been reduced on an average of 15 per cent., as per the following schedule:

| | Present Price. | Former Price. |
|---|---|---|
| 500 units | $1.10 | $1.25 |
| 1000 units | 2.00 | 2.25 |
| 2000 units | 3.50 | 4.00 |
| 3000 units | 5.00 | 5.75 |
| 4000 units | 6.50 | 7.50 |

(By requests of physicians we have relisted the 500 units package.)

We had not supplied the Chicago Board of Health, previous to January 7, for a considerable length of time, nor would we, since the price at which they were purchasing their supply was less than that at which we could prepare it. Consequently, when we were asked for a quotation, we offered the high-potency serum only. We were not requested to quote on the weaker serum, the general distribution of which had been discontinued, and on which we would have been pleased to quote a price on request, at about cost of production. We have always endeavored to meet every reasonable demand that has been made for legitimate preparations, and if the Board of Health of Chicago or of any other city or state requires a low-potency serum for free distribution, we shall be glad to furnish it, and at about cost. In determining to offer but one potency of antitoxin we believed that the indigent sick were entitled to receive the same advantage of concentrated serum as the well-to-do.

Meanwhile, if the City of Chicago or any other city or town having a regularly organized health department refuses to supply reputable physicians with antitoxin for the treatment of the needy poor, we shall be glad to donate sufficient serum to meet such emergencies. The conscientious manufacturer recognizes the importance of saving life from diphtheria and protecting those exposed to contagion by immunization, just as thoroughly as does the conscientious physician.

The firms engaged in producing antitoxin have invested large sums of money, and are safeguarding the quality of the serum by every means that science, skill and money can command. The directors of the laboratories and their assistants are chosen solely by their scientific attainments; furthermore, we recognize that only by producing the highest standard of quality is it possible for such a business to be continued.

During the past few years the expense of preparing antitoxin has increased enormously. In addition thereto, the cost of syringes, needles and devices for injecting serum direct to the patient, has added materially to the expense, and it is solely by controlling the expense attending the exchange of the weaker potency for the higher potency that we believed it possible to effect such a saving as would enable us to reduce the price.

Relative to the profits accruing from the production of antitoxin, we shall be glad to have any accredited representative of THE JOURNAL or of the American Medical Association examine our books and learn the exact profit earned in the production of antitoxin.

There is no trust existing among the manufacturers of antitoxin, nor do we believe such an organization is possible, since the production of antitoxin is only a portion of the business of each firm. While it is true that the lists are practically the same, this is also true of the general and standard commodities offered.

The conclusion of your editorial that "Under no consideration must it be thought that physicians want a cheap antitoxin" is insured, since the United States Government has rigid regulations safeguarding its production, and, furthermore, the products are purchased, *from time to time*, in the open market and subjected to tests, and it would be exceedingly unwise for any firm to market an inferior product, under the careful supervision now practiced.

Meanwhile, it can be depended on that competition, which is keen among the different manufacturers of antitoxin, precludes the possibility of excessive prices being charged.

H. K. MULFORD.

### A Protest and Warning Against Use of Name.

NEW YORK CITY, Jan. 30, 1904.

*To the Editor:*—A concern styling itself the A. S. Valentine Chemical Company is advertising a preparation in the form of a capsule for which it claims scientific and wonderful value in the treatment of gonorrhea, its complications and sequelæ. Investigation shows that the A. S. Valentine Chemical Company is a corporation formed under the laws of the State of New Jersey, and that its incorporators are A. F. Evans, Frank L. Shelton and Nannie L. Shouse, all residents of Kansas City, Mo. This company has a small office at a pretentious address in New York City, which address it uses in its advertisements. The capsule they sell is a gelatin-coated thick fluid bearing the name "Benzol-Capsule Valentine." The contents of the capsule have been represented as "distilled and encapsulated by Valentine's special process."

As is admitted by the person in charge of the office, who is one of the directors, no person by the name of Valentine has ever been connected with the A. S. Valentine Chemical Company, nor has any person with this surname given it his or her consent to the use of this name.

In order to protect the profession and myself I call attention to the following facts:

1. That I have, in all my writings on gonorrhea, its complications and sequelæ, emphatically expressed my conviction that no drug or combination of drugs administered internally can be a specific in the treatment of these diseases.

2. That no drug or combination of drugs given by the mouth can destroy gonococci.

3. That I do not know the contents of the capsules sold by these people and that I certainly do not recommend them or any other secret preparation.

4. That neither I, nor any relative, nor any acquaintance of mine is in any manner connected with the A. S. Valentine Chemical Company.

5. That on Jan. 7, 1904, through my legal adviser, Henry C. Quinby, of this city, I formally requested the A. S. Valentine Chemical Company to desist from the use of the name Valentine, and on their refusal I caused a petition for an injunction against their so doing to be prepared for filing in the Circuit Court of the United States.

On January 20 the counselor of the so-called Valentine Company had an interview with my legal adviser, Mr. Quinby, which resulted in the former unequivocally advising his clients to cease using the word Valentine in any manner.

I will thank any of my colleagues to inform me of any violation of this promise, so that I may, for the sake of the public, the profession, and my own sake, prosecute as vigorously as the best possible counsel and any sum of money can.

Ferd. C. Valentine.

### Worthless Galenical Preparations.

New York City, Jan. 29, 1904.

*To the Editor:*—In a recent communication, printed in The Journal of the American Medical Association, I stated that one of the causes of therapeutic nihilism and therapeutic chaos was to be found in the inferiority of some drugs and in the great variability of galenical preparations. I pointed out the great importance of ordering galenical preparations from strictly reliable sources and referred to the advisability of prescribing the active principles of drugs in those cases where the active principles have been isolated. I want to give an additional illustration which very forcibly illustrates the correctness of my position. As is well known, the solid extract of nux vomica of the U. S. Pharmacopeia must contain 15 per cent. of alkaloids. Prof. Frederick J. Wulling of the University of Minnesota has just reported the analysis of a sample of extract of nux vomica, which contained *not a trace of alkaloid*, instead of 15 per cent. (The italics are Professor Wulling's.) The explanation given is that the extract was undoubtedly heated to too high a temperature in the process of evaporation. Many extracts become entirely worthless if heated too high, and this is done only too often by careless manipulators. Is it any wonder that some physicians become therapeutic nihilists? Suppose a physician uses an extract like the above in gradually increasing doses and fails to get any effect whatsoever—is it any wonder that the seed of skepticism is planted in his mind? Let the physician not condemn his weapons before he is sure that he used the right weapons and that they were properly tempered.

William J. Robinson, M.D.

110 East 128 Street.

## Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

### RADIUM IN CANCER.

Indiana, Jan. 28, 1904

*To the Editor:*—I have a patient suffering with cancer of the larynx who insists that I investigate radium in the hope of applying it in his case. Can you direct me to a reliable source for information?

W. M. H

Answer.—The subject of radium and its therapeutic use is involved in so much theory and speculation, as is usual with a new therapeutic agent, that it is impossible at this time to give an opinion as to its exact status in medicine. It will doubtless be found of value in some cancers and other skin affections, but probably not in so many diseases as some writers seem to think. We refer you to a paper by Dr. Inglis in this issue, to our editorials of May 9, 1903, p. 1293; July 11, 1903, p. 107; Aug. 1, 1903, p. 317; Aug. 8, 1903, p. 377, and to abstracts of papers as follows: By Exner and by Holzknecht, Wiener kl. Wochenschrift, No 27, 1903 in The Journal, p. 345, Aug. 1, 1903; by London, Berlin kl Wochen., No. 23, 1903, in The Journal, p. 400, xli, Aug. 8, 1903, by Dawson Turner and by J. Macintyre, British Med. Jour., Dec 12, 1903, in The Journal, p. 65, xlii, Jan. 2, 1904; by Tracy, N. Y. Med. Jour., Jan. 9, 1904, in The Journal, p 266, xlii, Jan 23, 1904.

### UNJUST CRITICISM OF A COLLEAGUE.

Nebraska, Jan. 27, 1904

*To the Editor:*—Thursday, January 14, I was called to see a 6-year-old boy, who for several days had complained of headache sore throat, loss of appetite, and who had appeared feverish to the parents' touch. I found the following: Temperature, 104.5; pulse 140; epiglottis and larynx congested and swollen, soreness to the touch on external parts, breathing troublesome, dark sores on tongue, gums, tonsils and as far down as I could see with the use of an ordinary tongue depressor; bowels very constipated severe headache and sweating. I had them use an antiseptic mixture containing nitrate, glycerin, cocain, etc., as an application every two hours, after first using a 5 per cent. carbolic acid solution as a cleansing agent. Then I kept his bowels open and administered iron, glonoin and aconite and gave at night a powder containing caffein citrate, morphin and acetanilid in aromatic powder. The fever hung around 102 or 103 until January 20, when several scabs came off with hemorrhages and the temperature went to 99.5 and the pulse to 110. January 23 the temperature and pulse were normal, no swellings, little soreness, and I ordered the boy out of bed for Sunday and ordered sulphur disinfection, as I realized that I had had a mild diphtheria. Sunday a competitor of mine called at the house, looked in the boy's mouth and, without asking me a word of the history or treatment, said: "Never was even a beginning to a mild diphtheria, and you need not disinfect at all Humbug." I would like to have your opinion on several things: 1 What would my history suggest to you was the case? 2. Could any physician go to a boy after he is well, or out of bed, look in his mouth and say justly, as this doctor did? 3. Is it professional?

Answer.—1. The history suggests diphtheria or some infectious disease, but one at a distance can not judge accurately. Only a bacteriologic examination could settle the diagnosis absolutely 2. No. 3. No.

### THE RELATION OF OVULATION AND THE TIME OF IMPREGNATION TO MENSTRUATION.

North Dakota, Jan. 22, 1904

*To the Editor:*—If intercourse resulting in pregnancy occurs only a few (two to four) days before the menstrual period, would the expected menstruation occur as usual, or would the suppression begin from the time of intercourse and impregnation?

C. E M

Answer.—Much has been written on this subject and some effort has been made to solve the problem by experiments, but there is not yet agreement on the data and their interpretation It is generally admitted that there is some genetic relation between ovulation and menstruation, but whether ovulation occurs during menstruation, during the period of premenstrual swelling, after menstruation, or in the intermenstrual period, is not certainly known. Moreover, it is not known how long the free unfertilized ovum can exist nor how long the process of ripening, that is, the casting off the polar bodies, takes. It is known that the spermatozoa can live hours and days in the healthy genital passages of the woman. It is probable that the ovum escapes before or during or just after menstruation and remains intact and capable of being fertilized by the spermatozoa received during intercourse shortly after the end of menstruation. Fruitful intercourse which occurs later than one week after menstruation is probably to be ascribed to the fertilization of an egg that belongs to the period of the falling menstruation. Intercourse within a day or two of menstruation, if it results in fertilizing an ovum, may either prevent the appearance of the menstrual discharge or cause it to be much smaller in amount than usual. This statement seems to agree best with clinical facts known concerning the duration of pregnancy. If pregnancy results from a single coitus it lasts, as a rule, about 273 to 274 days. This corresponds with the common method of reckoning 280 days from the first day of the last menstruation. If menstruation lasts on an average four to five days, coitus, occurring two to three days later, results in the fertilization of an egg already present. If, as held by some, the spermatozoa are retained in the tube acting as a receptaculum seminis until the escape of the ovum just before the next menstrual period, the real length of the pregnancy dating from fertilization would be two or three weeks less, or 250 to 260 days. It is a fact, however, that the duration of pregnancy dating from coitus which occurs shortly before menstruation is generally about 274 days, or 295 to 300 days dating from the last menstruation. Since, then, the duration of pregnancy dating from coitus is about the same whether intercourse occurs shortly after menstruation or shortly before expected menstruation, it seems probable that the egg fertilized in the first instance is from a different period than that of the latter.

### THE EFFECT OF SCARLET FEVER, MEASLES, ETC., ON THE MILK OF NURSING WOMEN.

Glenville, Pa., Jan. 25, 1904

*To the Editor:*—I have seen many mothers, who were having measles, diphtheria and scarlet fever, nurse their children. The practice is common in my section. Have there ever been studies made of mother's milk under such conditions as to the danger or immunity to the child? Can you refer me to any literature on the subject? W. O. S.

Answer.—The propagation of tuberculosis through milk, especially cow's milk, has been the subject of considerable discussion and some investigation. Little or nothing has been done in regard to the propagation of scarlet fever and measles through this channel. Many epidemics of scarlet fever have been attributed to the supply of cow's milk. The greater number of these have been reported from England. It was formerly thought that the contagion came from the cow that was affected with a disease identical with scarlet fever. It is generally admitted that in epidemics which are really caused by milk supply the milk is contaminated by the milker or some one who has something to do with the handling of the milk or is living in the rooms where it is cared for or stored. Nursing women, while not exempt from these contagious diseases, are not very often affected, partly because of lessened liability of adults and partly because of decreased danger of infection. Scarlet fever of the puerperium was formerly thought to be common. These cases were almost always due to genital wound infection with skin and throat manifestations and were not cases of true scarlet fever. When a nursing woman is attacked with any acute febrile disease there is generally a diminution in the milk secretion while the proportion of solids is changed, albuminous constituents and the salts being increased. It is probable, however, that the quantitative changes in the chemical constituents of the milk are of less importance than formerly supposed. For the last few years much attention has been given to the milk ferments, and it is probable that these biologic constituents are very important in determining the value, digestibility and assimilability of milk. The study of the ferments as changed by the acute febrile diseases has not yet been undertaken, for this field of investigation is as yet very new. If our correspondent will keep on the lookout in the journals of physiologic research he will no doubt soon find that some worker has entered this interesting field.

In regard to the practical question of withdrawing the child from the breast, it is probably better to let the child continue nursing, if the attack is not very serious. Before the question arises the chance for and danger of infection has already occurred. Further danger of infection is rather from exhalations from the throat than from breast milk. The biologic and chemical changes in the milk are probably not so important as to counterbalance the advantages of the maternal secretion. In a more severe case in which the condition of the mother is serious and when nursing would be a strain on her, of course, the child must be withdrawn at once.

## Marriages.

H. B. Hargus, M.D., to Miss Lena S. Applegate, both of Klamath Falls, Ore., January 9.

Frederick Harrison, M.D., Fordyce, Ark., to Miss Fannie Jones of McCrory, Ark., January 14.

John C. Malone, M.D., Linden, Ala., to Miss Virginia Prowell of Dayton, Ala., January 13.

Frederick J. Kalteyer, M.D., Philadelphia, to Miss Helen Redmond, in New York City, January 15.

H. Stokes Dobiss, M.D., Atlantic City, N. J., to Miss Effie Fickens of Bridgeport, Conn., January 11.

Wallace A. Ort, M.D., Wellston, Ohio, to Miss Stacey Belle Elliott of Columbus, Ohio, at Hamilton, Ohio, in December last.

## Deaths.

**John Curtis Jones, M.D.** University of Edinburgh, Scotland, 1860; a member of the American Medical Association; surgeon in the Confederate Army; member of the Ninth International Medical Congress; member of the State Board of Medical Examiners; some-time vice-president of the Texas State Medical Association; died recently at his home in Gonzales, Texas.

**John W. Harriman, M.D.** State University of Iowa, Iowa City, 1891, professor of anatomy in the State University of Iowa; formerly surgeon-major Fiftieth Iowa Volunteer Infantry; a member of the American Medical Association, died in Iowa City, January 25, three weeks after an operation for appendicitis, aged 38.

**Edward B. Dana, Jr., M.D.** College of Physicians and Surgeons, New York, 1889, died from pneumonia at his home in Metuchen, N. J., January 21, aged 40. He was president of the borough board of health and permanent delegate to the state medical society.

**Egbert D. Sutherland, M.D.** College of Physicians and Surgeons, Chicago, 1885, of Bay City, Mich., who served with the Thirty-third Michigan Infantry, U. S. V., in the Spanish-American War, died from consumption in Detroit, after a long illness, January 25.

**William W. Firestone, M.D.** Charity Hospital Medical College, Cleveland, Ohio, 1865, a member of the American Medical Association, and one of the oldest and most esteemed practitioners of Wooster, Ohio, died at his home in that city, January 25, aged 61.

**Oliver Chase Wiggin, M.D.** Harvard University Medical School, Boston, 1866, some-time president of the Rhode Island Medical Society, and president and secretary of the Providence Medical Association, died in Jacksonville, Fla., Feb. 3, 1903, aged 63.

**Aaron S. Van Buskirk, M.D.** Medical College of Ohio, Cincinnati, 1876, died at his home in Fort Wayne, January 22, a day after an emergency operation for gallstones had been performed, aged 56. At the time, he was convalescing from pneumonia.

**J. J. Arthur Liebertanz, M.D.,** of Zurich, Switzerland, a passenger on the North German Lloyd steamer *Hannover*, was found dead in his cabin on the steamer in Baltimore, January 26, from the effects of an overdose of morphin, aged 42.

**George H. R. Bennet, M.D.** University of the City of New York, 1860, surgeon of the Twenty-third New York Volunteer Infantry in the Civil War, died suddenly from apoplexy at his home in Brooklyn, N. Y., January 26, aged 66.

**Charles J. Warner, M.D.** Cleveland Medical College, 1862, a member of the American Medical Association, died at his home in Congress, Ohio, from cancer of the stomach, January 23, after an illness of several weeks, aged 68.

**John B. Murphy, M.D.** College of Physicians and Surgeons of Ontario, Toronto, 1876, medical superintendent of the Hospital for the Insane, Brockville, Ont., died suddenly from heart disease at that place, January 17, aged 54.

**Hugh Spears, M.D.** Faculty of Medicine of Queen's University, and Royal College of Physicians and Surgeons, Kingston, Ont., 1873, was found dead in bed, from asphyxiation by gas, Nov. 25, 1903, aged 69.

**William Elliott, M.D.** Chicago Medical College, 1884, while driving across the Illinois Central tracks at Peotone, January 11, was struck by a train and sustained injuries from which he died January 18, aged 48.

**Robert M. Weed, M.D.** New York Homeopathic Medical College and Hospital, 1880, of New Rochelle, N. Y., died at Mount Vernon, N. Y., from disease of the liver of long standing, January 26, aged 49.

**Frederick A. C. Emerson, M.D.** Medical School of Maine at Bowdoin College, Brunswick, 1883, died at his home in Garland, Maine, January 15, from consumption, after an illness of nearly two years, aged 44.

**Selden Whittaker Crowe, M.D.** National Medical College, Washington, D. C., 1857, died at his home in New York City, January 24, from pernicious anemia, after an illness of four months, aged 68.

# Association News.

**Atlantic City Hotel Headquarters.**—The following hotels have been selected by the Hotel Committee as headquarters for the various sections of the American Medical Association during the annual session, June 7-10, 1904, at Atlantic City. The committee have selected the best hotels along the beach, and in each case have chosen a hotel as near the meeting hall of the respective sections as possible, so as to reduce to the minimum the distances between headquarters and meeting places.

| SECTION. | HOTEL. |
|---|---|
| General Headquarters............. | Marlborough House. |
| Practice of Medicine.............. | Hotel Traymore. |
| Obstetrics and Diseases of Women | Hotel St. Charles |
| Surgery and Anatomy............. | Haddon Hall. |
| Hygiene and Sanitary Science...... | Garden Hotel. |
| Ophthalmology.................... | Seaside House. |
| Diseases of Children.............. | Hotel Dennis. |
| Stomatology...................... | The Islesworth. |
| Nervous and Mental Diseases....... | The Brighton. |
| Cutaneous Medicine and Surgery... | The Shelburne. |
| Laryngology and Otology.......... | The Strand. |
| Materia Medica, Pharmacy and Therapeutics...................... | Young's Hotel. |
| Pathology and Physiology......... | The Windsor. |

Any information with regard to rates, location, reservation of rooms, etc., will be cheerfully given by the committee, who invite correspondence on the subject.

Wm. Edgar Darnall, M.D.,
Chairman Hotel Committee, Atlantic City, N. J.

# The Public Service.

## Army Changes.

*Memorandum of changes of station and duties of medical officers U. S. Army, for the week ending Jan. 30, 1904:*

Banta, Wm. P., asst.-surgeon, ordered to Fort Clark, Texas, for temporary duty.

Turnbull, Wilfrid, asst.-surgeon, granted two months' leave of absence to go beyond the sea.

Kirby-Smith, R. M., asst.-surgeon, granted twenty days' leave, for extension of seven days.

Hutton, Paul C., asst.-surgeon, relieved from further duty at Peking, China, and ordered to General Hospital, Fort Bayard, N. M.

Hansell, H. S., asst. surgeon, assignment to Manila, P. I., revoked, and instead ordered to legation guard, Peking, China, for duty.

Carpenter, Alden, contract dental surgeon, ordered to Fort Walla Walla, Wash., for temporary duty.

Voorhies, Hugh G., contract dental surgeon, on temporary duty at Plattsburg Barracks, N. Y., has been granted seventeen days' leave from January 17.

## Navy Changes.

Changes in the medical corps of the Navy, week ending Jan. 30, 1904:

Arnold, W. F., surgeon, sick leave extended two months.

Spear, R., P. A. surgeon, ordered to the Naval Hospital, Washington, D. C.

Shipp, E. M., P. A. surgeon, ordered to the Naval Hospital, New York.

Stone, M. V., asst.-surgeon, retired from active service on account of disability incident to the service.

Payne, J. H., Jr., P. A. surgeon, detached from the *Wabash* and ordered to the Naval Hospital, San Juan, P. R.

Morse, E. T., pharmacist, detached from the *Navy Yard, Portsmouth, N. H.*, and ordered to the Naval Laboratory.

## Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the fourteen days ended Jan. 28, 1904:

Wertenbaker, C. P., P. A. surgeon, granted leave of absence for five days from January 21. Detailed to make inspection of places in Mexico and the Texas border recently infected with yellow fever.

Rosenau, M. J., P. A. surgeon, granted one day's leave of absence under Paragraph 189 of the Regulations.

Greene, J. B., P. A. surgeon, granted leave of absence on account of sickness for fifteen days from January 26.

von Ezdorf, R. H., P. A. surgeon, granted leave of absence for thirteen days from January 25.

Anderson, J. F., P. A. surgeon, granted leave of absence for six days from Jan. 25, 1904, under Paragraph 191 of the Regulations.

McClintic, T. B., asst-surgeon, granted leave of absence for six days from Jan. 25, 1904, under Paragraph 191 of the Regulations.

Foster, S. B., A. A. surgeon, granted leave of absence for ten days from January 17.

Schug, F. J., A. A. surgeon, granted leave of absence, Dec. 22, 1903, to Jan. 5, 1904, on account of sickness.

Walker, R. T., A. A. surgeon, leave of absence granted for twenty days from Jan. 13, 1904, revoked.

Allen, G. C., pharmacist, on being relieved from temporary duty at Louisville, Ky., by Pharmacist G. O. Ferdinand, to rejoin station at New Orleans.

Holt, E. M., pharmacist, relieved from duty at Louisville, Ky., and directed to proceed to Washington, D. C., and report at Bureau for temporary duty.

Ferdinand, G. O., pharmacist, to proceed to Louisville, Ky., and report to the medical officer in command for duty and assignment to quarters.

### BOARDS CONVENED.

Board convened at Washington, D. C., Jan. 25, 1904, for the physical examination of officers for promotion and applicants for admission to the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon General W. J. Pettus, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

Board convened at Washington, D. C., Jan. 26, 1904, for the physical examination of such officers of the Revenue-Cutter Service and applicants for admission thereto as may present themselves. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

Board convened at the Marine Hospital, Port Townsend, Wash., Feb. 1, 1904, for the physical examination of an office of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon J. H. Oakley, chairman; P. A. Surgeon N. H. Foster, recorder.

### PROMOTIONS.

Asst.-Surgeons W. C. Billings, J. W. Kerr and G. M. Corput commissioned as P. A. surgeons, to rank as such from Dec. 29 and 31, 1903, and Jan. 6, 1904, respectively.

### APPOINTMENT.

Ferdinand, George O., of New York, appointed pharmacist of the third class.

## Health Reports.

*The following cases of smallpox, yellow fever, plague and cholera* have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended Jan. 29, 1904:

### SMALLPOX—UNITED STATES.

California: Berkeley, Dec. 31-Jan. 7, 1 case; Los Angeles, Dec. 26-Jan. 2, 1 case; San Francisco, Jan. 10-17, 2 cases.

Colorado: Colorado Springs, Jan. 8-16, 1 case; Denver, Nov. 28 Dec. 26, 9 cases.

Illinois: Cairo, Jan. 21, 4 cases; Jan. 16-23, Chicago, 2 cases; Danville, 4 cases.

Indiana: Evansville, Jan. 16-23, 2 cases.

Louisiana: New Orleans, Jan. 9-16, 4 cases, 3 imported.

Maine: Jan. 21, Smithfield, 1 case; Stacyville, 11 cases.

Maryland: Baltimore, Jan. 16 23, 1 case.

Michigan: Jan. 16-23, Detroit, 2 cases; Grand Rapids, 1 case; Port Huron, to Jan. 23, 3 cases.

Missouri: St. Louis, Jan. 9 23, 21 cases.

New Hampshire: Jan. 16-23, Manchester, 2 cases; Nashua, 1 case.

New Jersey: Jan. 16-23, Plainfield, 1 case imported; Trenton, 8 cases.

New York: Buffalo, Jan. 8-23, 4 cases; New York, Jan. 16-23, 5 cases, 1 death.

Ohio: Bucyrus, Jan. 8-23, 22 cases; Jan. 15-22, Cincinnati, 5 cases, 1 death; Cleveland, 3 cases; Dayton, Jan. 16-23, 5 cases.

Pennsylvania: Jan. 16-23, Allentown, 1 case; Johnstown, 1 case, 1 from suburban district; Philadelphia, 106 cases, 13 deaths; McKeesport, 5 cases; Reading, 4 cases; Titusville, 1 case; Williams port, 4 cases.

South Carolina: Charleston, Jan. 16-23, 3 cases.

Tennessee: Nashville, Jan. 16-23, 3 cases.

Utah: Salt Lake City, Jan. 8-16, 7 cases.

Wisconsin: Milwaukee, Jan. 16-23, 19 cases.

### SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Dec. 19-26, 8 cases.

Brazil: Pernambuco, Dec. 1-15, 15 deaths; Rio de Janeiro, Dec. 20-27, 40 cases, 40 deaths.

Canada: New Brunswick, Newcastle, Jan. 21, 1 case imported from Portland.

France: Paris, Jan. 2-9, 16 cases.

Great Britain: Jan. 2[illegible] case; Leith, 1 case; Liverpool, 1 case; Newc[illegible]ses; South Shields, 1 case; Sunderland, 7 cases [illegible] Jan. 8-15, 44 cases, 3 deaths; Nottingham, Dec [illegible]es, 1 death; Sheffield, Dec. 26-Jan. 2, 1 case.

India: Bombay, Jan. 15-29, 5 deaths; Karachi, Dec. 20-27, 2 cases, 1 death.

Italy: Catania, Dec. 31-Jan. 7, 1 death.

Mexico: City of Mexico, Dec. 13-Jan. 10, 4 deaths.

Russia: St. Petersburg, Dec. 26 Jan. 2, 31 cases.

Spain: Santander, Jan. 4-11, 8 cases.

Turkey; Smyrna, Dec. 20-Jan. 3, 11 deaths.

### YELLOW FEVER.

Brazil: Rio de Janeiro, Dec. 20-27, 3 cases, 3 deaths.

Jamaica: Kingston, Dec. 26-Jan. 9, 2 cases, 2 deaths.

Malta: Dec. 26-Jan. 2, 4 cases, 1 death.

Mexico: Merida, Jan. 3-16, 1 case, 1 death; Vera Cruz, Jan. 8-16, 2 cases.

Venezuela: Maracaibo, Dec. 20-27, 1 case, 1 death.

### PLAGUE—UNITED STATES.

California: San Francisco, Jan. 10 13, 3 deaths.

### PLAGUE—INSULAR.

Hawaii: Honolulu, Jan. 10, 1 death.

### PLAGUE—FOREIGN.

Brazil: Pernambuco, Nov. 15-Dec. 15, 9 deaths; Rio de Janeiro, Dec. 20-27, 9 cases, 3 deaths.

India: Bombay, Dec. 15-20, 120 deaths; Karachi, Dec. 20-27, 7 cases, 6 deaths.

Mauritius: Dec. 24-31, 53 cases, 29 deaths.

CHOLERA.

Java: Batavia, Dec. 5-12, 14 cases, 3 deaths.

Turkey in Asia: Diarbekir, Dec. 15-20, 53 cases, 28 deaths; Hitt, Dec. 13-15, 8 cases, 4 deaths; Kerbela, Dec. 13-20, 447 cases, 443 deaths.

## Medical Organization.

### California.

Pasadena Medical Society.—At the annual meeting held January 19 the Pasadena Medical Society formally dissolved to become the Pasadena branch of the Los Angeles County Medical Society. Dr. Fitch C. E. Mattison was elected chairman; Dr. John E. Janes, clerk, and Dr. Charles D. Lockwood, councilor.

### Indian Territory.

Greater McAlester Medical Society.—Physicians of South McAlester and its vicinity met in South McAlester, January 22, and organized a medical society, appointed a committee to draft a constitution and by-laws, and elected the following officers: Dr. Eben N. Allen, South McAlester, president; Dr. Frank L. Watson, Alderson, vice-president, and Dr. Le Roy Long, South McAlester, secretary and treasurer.

### Massachusetts.

North Berkshire Medical Association.—This association has so amended its by-laws that graduates of all regular medical schools are eligible to membership.

### New Hampshire.

Carroll County Medical Association.—A meeting of the society was held at Sanbornville, January 19, at which the society reorganized on the standard plan, adopted a new constitution and by-laws, and elected the following officers: Dr. W. S. Davis, Sanbornville, president; Dr. Pearl J. Haskell, Sanbornville, vice-president; Dr. Ervin W. Hodsdon, Centerville, secretary; Dr. Nathaniel H. Scott, Wolfboro, treasurer, and Drs. J. W. Dearborn, Maplewood, and Stillman P. Getchell, Wolfboro, delegates to the state society.

### South Dakota.

State Fully Organized.—South Dakota is now organized according to the plan suggested by the American Medical Association, with the difference that in place of the county societies the state is divided into nine districts, with the same powers and duties as the county societies. All of the district societies are now organized, and the membership of the state society has more than doubled in the past year.

First (Aberdeen) District Society.—This society, which has been in active work for about fifteen years, at its last meeting, held in Aberdeen, January 19, abandoned its old constitution and by-laws, and adopted those recommended by the American Medical Association. It now has a membership of 62 and holds meetings on the third Tuesday of alternate months. The following officers were elected: Dr. Charles B. Mallery, Aberdeen, president; Dr. Lynn A. Pickering, Warner, vice-president; Dr. Henry J. Rock, Aberdeen, secretary, and Dr. Robert D. Alway, Aberdeen, treasurer.

## Society Proceedings.

### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*Ninety-Eighth Annual Meeting, held in Albany, Jan. 26-28, 1904.*

The President, Algernon T. Bristow, M.D., Brooklyn, in the Chair.

### THE ADOPTION OF THE UNION PLAN.

### President's Inaugural Address.

On Tuesday, January 26, the society was called to order and addressed by the President, Dr. A. T. Bristow. He said that 673 delegates and 462 members, or 1,135 persons, constituted the present membership of the state society. The total membership of the county societies was 5,680. It was estimated that the membership of the consolidated state medical organizations would be 5,700. He discussed other society matters, and called attention to the desirability of issuing a monthly journal instead of the annual transactions. He urged the part that the profession should have in the great medical problems before the state, and closed by emphasizing that the long-sought opportunity for union of the profession in New York was here.

### Report of the Committee on Consolidation.

Dr. Henry L. Elsner, Syracuse, read this most important report. It was very long, but was listened to with great interest. As we stated last week, it detailed the steps of the attempt at harmony, gave the means by which it had been brought so near, and included the new constitution. The report was also circulated in printed form.

### Dr. Jacobi's Address.

Dr. A. Jacobi, New York, chairman of the Joint Committee, then made an address in which he moved the adoption of the report. He urged all to catch the spirit of the hour, and seize this great opportunity to restore harmony to the ranks of the profession in this state. He spoke as follows:

"The report of the chairman of your Committee of Five encloses the work of the Joint Committee of Ten. As its chairman, I rise to add a few remarks to the complete historical review you have listened to. I do so with the expression of the most intense gratification, for it has never been my lot to assist at the labors of any body of men more engrossed by their work than has been this committee laboring for the consolidation of the two large state bodies.

"The report before you gives no idea of the time and efforts required by the task entrusted to this committee. At first it seemed we had plain sailing. Nothing appeared to be simpler than to consolidate two corporations eager to be consolidated. A large amount of detail work was expected, but the enthusiasm exhibited in the association and in the special October meeting of the medical society promised an easy fulfillment of our common intentions and wishes. There was perfect harmony. There never was an allusion to past difficulties, controversies or animosities; nor was there during the many and protracted meetings a single minute disturbed by the rumors spread now and then of alleged attempts at thwarting the will of the profession as represented in the joint committee. Its two halves worked with equal zeal. Naturally, the actual work could not be equally divided; without invidious discrimination, therefore, the chairman wishes to thank two members for the unusual amount of labor cheerfully undertaken and successfully carried out, namely, the chairman of your Committee of Five, Dr. Elsner, and the secretary of the joint committee, Dr. Wisner R. Townsend. Nor should I pass by the uninterrupted and unselfish aid unofficially given by our president, Dr. Algernon T. Bristow, and our legal counsel, Mr. Howard van Sinderen, without whose indefatigable coöperation and fertile resourcefulness we should have stranded many times. In connection with this statement, I wish it to be understood that whatever has been done by your committee, whatever has gone before the legislature, or has been presented to you, has been scrutinized, suggested, criticised or created by him.

"The legislature has not been slow in appreciating and rewarding the efforts of the medical profession in behalf of its unification. Those of us who lived in by-gone times and participated in the work of this society are aware that it took years of strenuous effort and persistent persuasion to convince legislators of the importance and general usefulness of state boards of examiners, of increased requirements for the matriculation in medical schools, etc. When at those different times we approached the legislatures we were always confronted with the reproach that the medical profession was no unity; that what one wanted the other opposed, and with the fact that legislators declared themselves unable to decide a question in regard to which medical men were not of one mind. We were told many times that if and when the medical profession came before the legislature as a united body with demands either in its own or the people's interest—both, as a rule, being identical—there would be no delay in complying with its wishes. That promise has been made good. Within a week the permissive bill asking for consolidation has been passed through the senate and the assembly, and signed by the governor. Our thanks are due to the kindly services of the Hon. Nathaniel Elsberg, and his and our friends in the senate and assembly, and the Governor, the Hon. B. B. Odell. Evidently there is no power in the land that would care to evade, or to disapprove, or claim a just ground to withstand the reasonable demands of the 11,000 physicians of the Empire State when united for a common purpose.

"The legislatures of the future will be glad to know that whenever a bill will arrive that is voiced by the united profession and deals with the sanitary, educational and other vital interests of the people of the state, they are safe in passing it. The mature judgment of the profession has not easily been mistaken. Indeed, whatever progress has been made in the scientific and moral evolution of the medical profession has been accomplished by the combined efforts of its rank and file, without the co-operation, and frequently against the opposition, of some medical schools or of alleged and self-complacent leaders. That is as it should be in a profession which is imbued with the democratic principles of the commonwealth, and with the consciousness of its predominant weight in the determination of the most vital interests of mankind.

"From the report read you learn that the consolidated medical profession will bear the time-honored name of the Medical Society of the State of New York; that its seal will be preserved: its continuance not interrupted, and the individual rights of members enhanced. There will be no privileged class of almost five hundred permanent members, some of whom have even lost their membership in county societies, and no danger from a possible predominance of such an aristocratic class. The house of delegates will count at least 150 members, in place of the nominating committee of nine. It can not elect its own members into offices. It is controlled by the referendum, which means an appeal to the total membership of the society in any doubtful or contested case. It takes the place of Congress in our political commonwealth. To it are referred legislation and administration, and it is renewed by annual election in the county societies according to the number of assembly districts, with this proviso, that every county society has at least one delegate. By being the legislative body, it leaves the meetings of the society free for its scientific work. The constitution and by-laws, formed under the eyes of legal authority, are safe from interference, and are subject to changes by the majority vote of the medical society.

"This is what is proposed for your adoption. Other points are referred to the future vote of the combined societies, so the question whether there shall be in the by-laws an ethical clause, whether the directory or journal or transactions shall be continued or not and the amount of dues. All this will be left for your five or six thousand votes to decide.

"You who met here as delegates or permanent members are in as momentous a position as any that the medical society was ever placed in during the century of its existence. Unification has been the demand of the vast majority of the profession of our state so long that it has become practically unanimous. Not of the state alone, however. The profession of the United States is listening to your verdict of this morning. While it is our pride that this is so, and that on our resolution the fate of the country's profession may depend—to know that the eyes of our brethren all over this broad land are on us this very moment, adds to our responsibility. Never was there during the life of this society a better opportunity for the display both of wisdom and of patience.

"It is admitted on all sides that both patience and wisdom are demanded more on the part of the medical society than of that of the association. The latter's organization is simpler and, being younger, it is not beset with old, in part contradictory, often repealed, frequently only half repealed laws extending over a hundred years. The autonomy of the county societies, which the joint committee has been anxious to preserve, unless wisely exercised, creates a difficulty. As their ratification of the new constitution and by-laws is demanded as a matter of course, their common sense, patience, wisdom and patriotism are required to a high degree. They will consider that laws are not made forever; they are not the masters of man, but the expression of their will as modified by time, usages, and changed necessities. Even the sacred constitution of the United States had to be modified by the modern requirements of the sons and grandsons of its makers. That is why it is recommended that if there be any points in the proposed constitution and by-laws displeasing one or the other, you are still safe in adopting them all. There are six thousand of us, and there will be more. Every year your constitution and by-laws may be altered if you deem proper. Your delegates will change, and your referendum is more powerful than any house of delegates. What we are after is union. More than once a member of your joint committee got up to say: 'We have been sent here to harmonize and to unify and to consolidate. We can not return to our masters and tell them we have missed our opportunities to execute their will. I still hear the ring of enthusiastic applause when the unanimous vote calling for unity brought a tear to many an eye. And unity it shall be.' I never heard the duties of sound citizenship expressed more emphatically.

"After unification, we shall be satisfied that nothing will ever sever us again. For there will never again be a diversity of principles like twenty-two years ago. There will be a common faith, aim and altar. We shall take in the medical brotherhood the place which belongs to us, and work for the ideals, scientific, moral and practical, such as no other profession can realize, together with our peers all over the Union. We must or need split up into parties nevermore. To the undivided and indivisible body medical the American people will look for authoritative guidance in matters of sanitation, education and forensic legislation. What a Greek sage demanded should and may become true, viz., that the commonwealth will be advised and ruled by the physician. It is in this spirit that I appeal to you not to miss this opportunity of initiating for our glorious profession an epoch of fraternity, vastly increased usefulness and almost ideal possibility for benefiting ourselves, our brethren, and numerous millions. I appeal to you as one of your oldest members who has stood by you in prosperity and distress, in peace and war; and long and lately as a friend of reconciliation and union of the two great medical bodies of the state. The confidence both of your own committee and that of the association has permitted me to preside over their long and laborious deliberations. That is why I feel I have a right to represent in this solemn hour the whole profession of the state in its anxious longing for consolidation, not as an officer, or a delegate, but as a peer among peers. That is, Mr. President, why I have risen to move the adoption of the following resolution:

*Resolved*, That the report of the Joint Committee of Conference be accepted and that the proposed agreement for the consolidation of the Medical Society of the State of New York and the New York State Medical Association be and the same is hereby approved, and the president of the society is hereby authorized and directed to execute the same in the name and behalf of the society, and the secretary is hereby authorized and directed to affix the corporate seal thereunto; and be it further

*Resolved*, That the committee of the society heretofore appointed for the purpose of bringing about the consolidation, namely, Dr. Henry L. Elsner, Dr. A. Jacobi, Dr. A. Vander Veer, Dr. George R. Fowler and Dr. Frank Van Fleet, be and they are hereby continued as such committee, with full power and authority to do whatever may be necssary to carry the agreement into effect.

The motion of Dr. Jacobi was seconded by Dr. D. B. St. John Roosa, and following him, Drs. William Warren Potter, Willis G. Macdonald and Roswell Park spoke in favor of the motion, and urged unanimous action. The resolutions were then enthusiastically adopted without a dissenting vote. It was then ordered that the report of the committee be printed and a copy sent to each member.

## THE SCIENTIFIC PAPERS.

The papers read at this meeting were of a high quality. There were three subjects on which there were symposiums, diabetes, nephritis and abdominal pain, and on which there was valuable exchange of opinion.

### Symposium on Diabetes.

**Dr. R. M. Pearce**, Albany, discussed the pathology of diabetes, and was of the opinion that all forms of diabetes were not due to disease of the pancreas.

### Physiologic Chemistry of Diabetes.

DR. DAVID EDSALL, Philadelphia, discussed the various theories. He thought there was much to be learned concerning the nature of different varieties of sugar. In diabetes there might be a defect in glycogen construction or an excessively rapid conversion of glycogen into sugar.

### Medical Treatment of Diabetes.

DR. WILLIAM H. THOMSON, New York, was averse to prescribing the opium derivatives in diabetes, firmly believing that no permanent good could possibly follow the use of medicines of this class. He had for many years made use of cod liver oil, and had found it very beneficial except in the obese form or in those leading a very sedentary life. Arsenic was also useful. In severe cases, he began by giving 15 grains each of antipyrin and benzoate of sodium four times a day, changing after a time to 15 grains of aspirin and 10 grains of bismuth salicylate. Alkaline waters were often useful, but if used freely for a long time they would hasten emaciation.

### General Management of Diabetes.

DR. F. C. SHATTUCK, Boston, said that the diet should be regulated, not only as to the articles of food, but as to the quantity of each. In the milder cases, after one or two months of a strict diabetic diet, it might be proper to cautiously test the patient's ability to take starch, but a much longer time would be required in more severe cases. If diacetic acid and acetone were present in the urine, a radical change in the diet would be dangerous. The diabetic should be warmly clad, and while having rest of body and mind should have a moderate amount of exercise.

### The Occurrence of Diabetic and Non-Diabetic Glycosuria in the Same Individual.

DR. HEINRICH STERN, New York, read this paper. His conclusions were: (1) The diabetic state may be established before glucose is excreted by the urine: (2) glycosuria is a symptom of many other disturbances, both ectogenous and endogenous; (3) with the aid of other disturbing factors it is possible to differentiate between the diabetic and non-diabetic form; (4) duplex mellituria is the result of two concurrent or intercurrent affections of dissimilar character, having glycosuria as the one symptom in common, and (5) duplex mellituria depends on the alternate prominence of one set of symptoms, including glycosuria.

### Addresses by Drs. Bristow and Hadley.

Tuesday evening two excellent addresses were given. The president's annual address, by Dr. Algernon T. Bristow, Brooklyn, was on "The Present Status of the Medical Expert," and clearly laid the burden of the present medicolegal difficulties on the legal profession. This address will appear in THE JOURNAL shortly.

The other address, on "Conflicting Claims of General Education and Professional Education," by Arthur T. Hadley, LL.D., president of Yale University, is given elsewhere in this issue.

### Officers Elected.

The following officers were elected: President, Dr. Hamilton D. Wey, Elmira; vice-president, Dr. Joseph D. Bryant, New York; secretary, Dr. Frederic C. Curtis, Albany; treasurer, Dr. O. D. Ball, Albany.

The society voted in favor of holding semi-annual scientific meetings successively in Buffalo, Rochester, Syracuse and New York.

*(To be continued.)*

---

## THE BALTIMORE TUBERCULOSIS EXPOSITION.

*Held at McCoy Hall of the Johns Hopkins University, Jan. 25-30, 1904.*

This great exposition, described by some as the greatest presentation of the subject ever given, was held under the joint auspices of the Tuberculosis Commission of Maryland, the State Board of Health of Maryland, and the Maryland Public Health Association. It was illustrated by charts, photographs, diagrams, models, instruments, tests, pathologic specimens, lectures, etc., and covered the history, distribution, varieties, causes, cost, prevention and cure of tuberculosis.

### The Addresses.

The formal opening was held at 8:15 p. m. January 25, when addresses were delivered by Governor Edwin Warfield, by Hon. Robert McLane, mayor of Baltimore; by Prof. William Osler, and by Mr. Frederick Hoffman of Newark, N. J. The governor highly commended the unpaid work of the Tuberculosis Commission, of which Dr. William S. Thayer is president, and spoke of the exposition as "the clinical and supplementary report of the commission." He promised that he would "gladly co-operate in the measures proposed." The mayor urged personal work and the receiving of appropriations from the legislature. Dr. Osler spoke of the apathy of the citizens, from which it seemed almost hopeless to arouse them. Mr. Hoffman, who is the actuary of a large life insurance company, spoke from large statistics. He assigned ten specific reasons for the marked but gradual reduction in the death rate from consumption in the last fifty years, viz.: The vast and far-reaching improvements in the housing of the population of large cities; the vast improvements in the direction of providing tenements and dwellings with more light and better ventilation; the diminution in the evils of overcrowding; the improvement in the morals of the people, making for a lesser degree of gross intemperance; improved methods of feeding of infants and adults with food of more nutritious quality, making for the building of a body of a higher degree of disease-resistance; improved economic conditions, especially in the direction of higher wages and shorter hours of labor, substituting possibilities of rest and recreation for overstrain and bodily exhaustion; the prohibition of child labor at early ages, making for constitutions better able to withstand the inherent disease-producing conditions of factory life; far-reaching improvements in the sanitary conditions of factories as the result of systematic factory inspection and an intelligent public health administration; improvements in school hygiene providing for children at the critical-age period more room, more light and better ventilation than was formerly the case; and, finally, a tendency toward a higher standard of life and a more deliberate view of life and the value and worth of living. The decrease in the death rate from consumption in American cities was from 32.5 per 10,000 in 1871 to 19.2 per 10,000 in 1900. Mr. Hoffman then went on to speak of race, marriage, occupation, religion, etc., and showed how all these were concerned in the prevalence and mortality of consumption. The high mortality of the colored race, which is 49 per 10,000, to 17 per 10,000 in the whites, was dwelt on, and is not to be explained solely by unfavorable surroundings, but is due to racial differences, to a less vigorous vital resistance on the part of the negro. The native population of native stock shows the lowest mortality from consumption, while the Irish show the highest. From 15 to 34 years, one-third to one-half of the total mortality is from consumption. Many interesting points were brought out with reference to marriage, occupation and religion.

The second day's address was made by Dr. Lawrence F. Flick of the Phipps Institute, Philadelphia, who spoke on "House Infection of Tuberculosis." He laid great stress on the house as an agent of infection, and said that practically contagion is limited to it. In proper house disinfection is to be found the key to the entire problem of stamping out tuberculosis.

On the third evening the addresses were by Dr. Mazyck P. Ravenel of the University of Pennsylvania and Dr. D. E. Salmon, chief of the Bureau of Animal Industry, Department of Agriculture, Washington, D. C. With reference to transmission from man to cattle, Dr. Ravenel said this was first proven in 1868 by Chaveau, who selected only animals from the Jura Mountains, where the disease was unknown. Direct experimental evidence of transmission from cattle to man is wanting, but several such cases had occurred under his observation from accidental inoculation, some ending in general infection and death. Transmission by injection of tuberculous meat, however, is difficult to prove, as we can not exclude all other sources of infection. Yet the evidence of this is as good as in cases which we admit to be by inhalation. The bovine organism has also been found in the intestines of children dead of intestinal tuberculosis. The chief difference between the bovine and human bacillus is their relative virulence, this being vastly greater in the former. We are justified in saying that bovine tuberculosis is transmitted to the human race, chiefly to infants, in a certain, at present undeterminable, proportion of instances and is, therefore, a menace to public health. Dr. Salmon gave the results obtained on this subject by himself and assistants in Washington.

The fourth day's address was made by Dr. S. A. Knopf of New York, who said that consumption is curable by pure air, pure food and pure water; that it is not hereditary and that it is communicated by inhalation, ingestion and inoculation. He showed several forms of spittoons. He spoke of the danger of kissing, putting fingers and pencils in the mouth, and expectorating on the floors. Dr. Knopf continued with many practical suggestions, and urged that philanthropists could find their best opportunities for doing good in this field.

The fifth day's address was by Dr. George Adami, Montreal, on "Facts, Half Truths and the Truth about Tuberculosis." He pointed out the difference between many popular conceptions and the real facts as regards this great scourge.

On the sixth day Professor Welch spoke, and Dr. Charles H. Potter gave demonstrations with the lantern of the pathology of tuberculosis. A similar demonstration by Dr. Huber of New York concluded the exposition in the evening.

### The Exhibit.

The exhibit was held in the corridors, in a room opening into these and in the lower part of the large McCoy Hall. Statistics were much in evidence, nearly 100 charts being shown. Many of the facts brought out in the address of Mr. Hoffman were here graphically exhibited. The relations of factory, tenement and sweat shops to tuberculosis were next shown, and the conditions prevailing in Baltimore, New York, Boston, Chicago, etc., were pointed out by photographs.

Especially valuable was the exhibit of prophylactic measures employed by state and municipal boards of health. Pictures of sanatoria and dispensaries, both native and foreign, illustrated the most modern and approved methods of treatment. There were many models of tents, one of the most observed being the Fisher tent, fully equipped for patient and attendant. This was pictured and described in The Journal, Dec. 26, 1903. Other models of tents were the Gardiner, from Colorado Springs and another which is used successfully on the health farm of the Young Men's Christian Association near Denver.

There was a series of photographs showing infected streets and houses in Baltimore; another set showed how in the treatment the colony idea, the roof garden, the fire escape, the veranda could be converted to the use of the consumptive. The committee on Home Treatment and House Hygiene exhibited a model room furnished in all its details, and near this was an exhibit made by the Visiting Nurse Association. A large collection of books and portraits was shown in glass cases illustrating the history of tuberculosis from the earliest times down to the present.

The pathologic section consisted of specimens of tuberculous tissues and organs in man and animals, wax casts, etc., derived from the Army Medical Museum and from the museums of the University of Maryland, the Johns Hopkins Hospital, the Baltimore College of Physicians and Surgeons, and the city and state health departments.

A large map had been prepared by the health board, showing all the houses in which there has been a death from tuberculosis in the 10 years from 1890 to 1900. Each of these 11,582 deaths is indicated by a red dot. "Lung block," the worst area, consisting of two squares crowded with negroes, shows 175 deaths. The sweatshop pictures were very impressive. Among the institutions, etc., exhibited were the health departments of Chicago, New York City, Baltimore and Boston; Loomis Cottage Sanatorium, New York; Muskoka Sanitarium, Canada; Massachusetts State Sanatorium; Sharon Sanatorium; Stoneywold Sanatorium; Blackwell's Island Hospital; National Sanatorium, Canada; Bedford Sanatorium, etc. The "City Hall and Court House Sputistics" of Dr. Fulton were original and suggestive.

Sufficient to say, the exposition, unique in its way, was a perfect success. Crowds of people thronged the corridors during the entire week, hundreds stood during the lectures and hundreds were turned away unable to gain entrance to the large hall. Such an outpouring of people was remarkable and unexpected, and the attention, interest and enthusiasm with which they listened to the speakers and minutely examined the exhibits gives the greatest encouragement.

The arrangements were admirable. Dr. Fulton and his assistants were always at hand to pilot the crowds and visitors about and explain everything to them.

Many physicians and sanitarians from all parts of the United States and Canada were in attendance.

### Action on Tuberculosis Congresses.

At a conference held in McCoy Hall on the evening of January 28, presided over by Prof. William H. Welch, Baltimore, at which a number of representative physicians interested in the study of tuberculosis from various parts of the country were present, the following motion made by Dr. H. M. Bracken of St. Paul, Minn., and amended by Dr. William S. Thayer, Baltimore, was unanimously adopted: "Moved that the chair be authorized to appoint a committee with power to act, to consider the conditions existing with regard to the proposed tuberculosis congress and other national antituberculosis associations in the United States, also to consider the formation of a national committee to represent this country at the International Congress at Paris, and that the members of this conference will abide by the action of the committee—also that this committee have power to add to its membership."

In accordance with this motion, Prof. William H. Welch appointed the following gentlemen to this committee: Dr. William Osler, Baltimore; Dr. Edward L. Trudeau, Saranac Lake, N. Y.; Dr. Theobald Smith, Boston; Dr. J. G. Adami, Montreal, Canada; Dr. Vincent Y. Bowditch, Boston; Dr. S. A. Knopf, New York City; Dr. Mazyck P. Ravenel, Philadelphia; Dr. Arnold C. Klebs, Chicago; Dr. Edward G. Janeway, New York City; Dr. Henry Barton Jacobs, Baltimore; Dr. H. M. Bracken, St. Paul, Minn.; Dr. Lawrence F. Flick, Philadelphia; Dr. Herman M. Biggs, New York City.

---

# Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Rhus Toxicodendron Poisoning.

The following combination is recommended by *Med. Pharm. Critic and Guide* in the treatment of ivy poisoning:

| | | | | |
|---|---|---|---|---|
| ℞. | Sodii hyposulph. | ℥i | 30 | |
| | Menthol | gr. v | | 30 |
| | Alcoholis | ʒi | 4 | |
| | Spts. etheris nitrosi | ℥i | 30 | |
| | Aq. destil. q. s. ad | Oi | 500 | |

M. Sig.: Apply locally with a soft sponge or on sterilized gauze.

### Formaldehyd.

Wainwright, in *Med. Mirror*, in speaking of formaldehyd as an antiseptic, germicide, disinfectant and deodorizer, states that the 40 per cent. solution, formalin, in 1-32,000 dilution preserves milk for several days; 1-25,000 strength is useful as a douche in leucorrhea; 1-3,200 for rinsing dairy cans:

1-2,000 for rinsing vessels intended for liquids liable to fermentation; 1-500 for irrigations of catheters and for mouth wash; 1-250 as a general disinfectant, solution for washing the hands, instruments, spraying sick-rooms, and as a deodorant. In the treatment of lupus, psoriasis and other skin diseases, it should be used in strength of 1-100.

The author also recommends formaldehyd in the treatment of hyperidrosis of the feet, in whooping cough and diphtheria, using a vapor or spray of 1 per cent. strength in the latter diseases. It is also of service in relieving the conditions in atrophic rhinitis and ozena, using it in dilute solutions applied locally after the application of cocain to the mucous surfaces. In the treatment of carcinoma of the cervix, with fetid discharge and severe hemorrhage, a 20 per cent. solution acts as a hemostatic, diminishes the discharge, fetor and pain. In cases of pharyngitis and tonsillitis, it is of value combined in diluted strength with glycerin. In chronic otorrhea, the ear may be syringed out daily with a formalin solution in the proportion of one dram to the pint (4.-500). As antidotes to formalin in cases of poisoning when given internally, a few drops of aqua ammoniæ well diluted, aromatic spirits of ammonia or liquor ammoniæ acetatis have proved to be very efficient.

### Creosotal in Croup.

Lazansky, in *Med. Council*, recommends the following combination containing creosotal in the treatment of croup contracted by children between the ages of five and ten years:

| | | | | |
|---|---|---|---|---|
| ℞. | Creosot. | gr. xlv-ʒi | 3-4 | |
| | Liq. ammon. anis. | m. xv | 1 | |
| | Syr. senegæ | ℥ss | 15 | |
| | Infus. ipecac. rad. | ℥iss-℥iii | 45-90 | |

M. Sig: One teaspoonful every hour until fever diminishes, then every two to three hours.

### Empyroform.

Skarlek, according to an abstract in *Amer. Med.*, has found empyroform to be beneficial in the treatment of eczema. It lessens the itching, has marked drying properties, and is non-irritant. It is useful in all stages of eczema. He employs the following combination:

| | | | | |
|---|---|---|---|---|
| ℞. | Empyroform | | | |
| | Pulv. amyli, āā | ʒvi | 24 | |
| | Liq. petrolati | ℥iss | 45 | |

M. Ft. unguentum. Sig.: Apply locally.

Empyroform is a combination of tar and formaldehyd. It is a brown powder with tar-like odor, insoluble in water but soluble in caustic alkalies and chloroform and liberates formaldehyd when heated.

### Pertussis.

The following combination is recommended by J. S. Howard, in *Med. Council*, in the treatment of whooping-cough:

| | | | | |
|---|---|---|---|---|
| ℞. | Acidi nitrici dil. | ℥i | 30 | |
| | Tinct. card. co. | ʒiii | 12 | |
| | Syrupi simplicis | ℥iiiss | 100 | |
| | Aquæ | ℥i | 30 | |

M. Sig.: One small teaspoonful every two hours.

The foregoing is especially recommended in infants, who have been exposed to the disease, as a prophylactic measure.

### Broncho-Pneumonia.

The following combinations are recommended in *Clin. Ther.*, in the treatment of catarrhal pneumonia:

| | | | | |
|---|---|---|---|---|
| ℞. | Ammonii chloridi | gr. lxxx | 5 | |
| | Syr. scillæ | ʒiii | 12 | |
| | Liq. ammon. acetatis q. s. ad | ℥iv | 120 | |

M. Ft. mistura. Sig.: One dessertspoonful in water every three to four hours.

One or two drops of the tincture of aconite may be added to each dose of the foregoing, carefully watching its effects; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Ammon. carb. | gr. xlv | 3 | |
| | Mucil. acaciæ | | | |
| | Syrupi simplicis, āā | ℥ss | 15 | |
| | Tinct. lavendulæ comp. | ʒii | 8 | |
| | Aquæ q. s. ad | ℥iv | 120 | |

M. Sig.: One teaspoonful in water every three hours to a child three years of age.

In cases where there is threatened respiratory failure the following may be substituted:

| | | | | |
|---|---|---|---|---|
| ℞. | Quin. sulph. | gr. xxiv | 2 | 60 |
| | Strych. sulph. | gr. 1/4 | | 015 |
| | Acidi hydrochlor. dil. | m. xv | 1 | |
| | Glycerini | ʒiii | 12 | |
| | Liq. pepsini q. s. ad | ℥iv | 120 | |

M. Sig.: One teaspoonful in water every three or four hours for a child five years of age; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Strych. sulph. | gr. 1/4 | | 015 |
| | Acidi hydrochlor. dil. | ʒi | 4 | |
| | Spts. chloroformi | ʒiv | 15 | |
| | Ext. cinchonæ liq. | ʒiii | 12 | |
| | Aquæ q. s. ad | ℥iv | 120 | |

M. Ft. mistura. Sig.: One teaspoonful for a child five years of age, every three or four hours.

### Enterocolitis.

A. Robin, in *N. Y. and Phila. Med. Jour.*, states that medication should be so directed as to render the gastric contents alkaline before being pushed on into the intestine. For such purposes the following combination is recommended:

| | | | | |
|---|---|---|---|---|
| ℞. | Calcii carb. precip. | | | |
| | Magnesiæ (calcined), āā | ʒiss | 6 | |
| | Sodii bicarb. | ʒi | 4 | |

M. Ft. chart. No. xii. Sig.: One after each meal.

Between the meals, to render the pain less, the following is advised:

| | | | | |
|---|---|---|---|---|
| ℞. | Lactose | gr. xv | 1 | |
| | Magnes. oxidi hydratis | gr. xxiiss | 1 | 50 |
| | Bismuthi subnit. | | | |
| | Cretæ prep., āā | gr. xii | | 75 |
| | Codeinæ | gr. 1/12 | | 005 |
| | Sodii bicarb. | gr. xv | 1 | |

M. Ft. chart. No. i. Sig.: As indicated to relieve the pain.

Milk alone is not recommended. The diet should include thin soups, bouillons, broiled or roasted meat without sauces, boiled fish and boiled vegetables. A glass of ale may be given once a day. Colonic flushings with boiled water should be given daily and very slowly with low pressure. Saline purgatives are contraindicated. Castor oil may be given in combination with extracts of belladonna and hyoscyamus. In some cases the following is preferable:

| | | | | |
|---|---|---|---|---|
| ℞. | Ext. aloes (Cape) | gr. xxx | 2 | |
| | Pulv. jalapæ | gr. xv | 1 | |
| | Res. scammonii | | | |
| | Res. cambogiæ, āā | gr. xv | 1 | |
| | Ext. belladonnæ | | | |
| | Ext. hyoscyami, āā | gr. iiss | | 15 |
| | Pulv. saponis, q. s. | | | |

M. Ft. pil. No. 1. Sig.: One to three pills at bedtime.

The author recommends cold compresses to the abdomen, and allowed to remain in place all night. Massage is also of benefit in these cases.

In prolonged painful paroxysms, avoid opium preparations and substitute cannabis indica as follows:

| | | | | |
|---|---|---|---|---|
| ℞. | Ext. cannabis indicæ | | | |
| | Ext. hyoscyami | | | |
| | Ext. belladonnæ, āā | gr. ss | | 03 |
| | Menthol | gr. iss | | 09 |
| | Alcoholis, q. s. | | | |
| | Syr. acaciæ q. s. ad | ℥v | 150 | |

M. Sig.: One tablespoonful every hour.

Locally the following liniment may be applied to the painful spots:

| | | | | |
|---|---|---|---|---|
| ℞. | Spts. chloroformi | ʒv | 20 | |
| | Ext. belladonnæ | | | |
| | Ext. hyoscyami | | | |
| | Ext. cannabis ind., āā | ʒi | 4 | |
| | Linimenti saponis | ℥iii | 90 | |

M. Ft. linimentum. Sig.: Apply locally as indicated.

### Tonics in the Convalescent Stage of Febrile Diseases.

The best general tonic after an acute illness, according to A. Caillé in *Post. Grad.*, is a change of air from the city to the country, from the mountains to the seashore, and vice versa. Diet and regulated digestion, exercise, massage baths and proper surroundings are of importance. The administration of dilute hydrochloric acid after meals will aid the digestion; and a normal digestion and nutritious diet will soon improve the composition of the blood. He recommends the following method of administering hydrochloric acid in such cases:

℞. Acidi muriat. dil. ......................ʒiv 15|
Sig.: Five to ten drops in sugar water after eating; or:
℞. Acidi muriat. dil.
Tinct. nucis vom., āā..................ʒii 8|
M. Sig.: Five to ten drops in sugar water after eating; or:
℞. Acidi muriat. dil. ......................ʒi 4|
Essentiæ pepsini ......................℥ii 60|
M. Sig.: One teaspoonful after eating, three times a day.

He recommends, before administering iron, arsenic, phosphorus or other drug tonics that the tongue be cleaned.

To improve the anemia he recommends the following combinations:

℞. Tinct. ferri muriatici ..................ʒi 4|
Elix. gentianæ comp. ..................℥ii 60|
M. Sig.: One-half to one teaspoonful three times a day; or:
R. Elix. calisayæ cum ferro et strych......℥ii 60|
Sig.: One half to one teaspoonful three or four times a day.

In such cases he also recommends the glycerophosphates and hypophosphites of iron.

Arsenic is of value given in the form of Fowler's solution, one to five drops (.06-.30) diluted in water *after meals.*

Phosphorus given in the form of Thompson's solution or elixir of phosphorus may be given to children in ten to twenty (.65-.13) drop doses in water three times a day.

## Medicolegal.

**Eighty Thousand Dollars for Personal Injuries.**—In International & Great Northern Railroad Company vs. Moynahan, a personal injury case brought by the latter party, an engineer, who was 38 years old, sound and earning $140 to $150 a month when injured, the Court of Civil Appeals of Texas holds that a verdict for $80,000 damages was warranted by evidence that he hovered between life and death for many months, suffering great agony, became a physical wreck, unable from his spinal injuries to move his head or preserve his balance naturally, was never without pain, was totally incapacitated for labor, one side was paralyzed, and his tendency was to grow worse.

**Injury to Practice and Use of Morphin by Wife.**—The Supreme Court of Georgia holds, in the case of Smith vs. Smith, that, in the trial of an action for divorce, brought by a husband against his wife on the ground of alleged cruel treatment, it is not error to reject evidence that she constantly quarreled with, abused and insulted her husband, and, by slandering him to her neighbors, injuriously affected his practice as a physician, etc. Nor is it error, in the trial of such a case, to reject evidence that the wife was an habitual user of morphin, and almost all of the time under its intoxicating influence.

**Transportation of Insane Persons.**—The Supreme Court of Georgia, which finds no authority directly in point, holds, in Owens vs. Macon & Birmingham Railroad Company, that the carrier can not absolutely refuse transportation to an insane person, but it may in all cases insist that he be properly attended, safely guarded, and securely restrained. And even where such precautions have been taken, it is not bound to afford him, if violent, transportation in the cars in which other travelers are being conveyed. And while there may be cases in which the convenience of other passengers should yield to the necessities of the unfortunate, the company may decline to receive one who at the time of entering the train exhibits signs of violence which indicate that his presence and conduct would tend to the manifest annoyance of others. So to do would ordinarily be better than to receive him on the promise of his attendants that he would be quiet, and, on the disorder continuing, force on the carrier the duty of deciding whether he should be ejected at a station where there might not be proper accommodations. Where, however, it becomes essential to transport one who, though violent and noisy, is not responsible for his actions, the company is entitled to seasonable notice, in order that it may make proper arrangements.

**An Inmate of a Hospital.**—In the case of Farrel vs. Security Mutual Life Insurance Company, the insured was asked if he had ever been an inmate of any hospital, and answered, "No." But it appeared that he had been admitted to a hospital, where he remained for from one to two weeks. A physician testified that he had visited him professionally, and suggested his removal to the hospital; that he went to the hospital, and examined him for twenty minutes to half an hour very carefully; that he was accepted at the hospital as his private patient. The physician further testified that he found nothing the matter with the man; that he made an entry of rheumatism *in order to qualify him* to be entered at the hospital, and that he ordered his removal to the hospital because he could give him better care, and under more satisfactory circumstances, than he would receive where he was. He explained that by better care he meant "better environment"—under better conditions—and that by "better conditions" he meant, "Well, if he touched a button he could have a servant come to his room any time day or night, or if he wanted a change of blankets, or a hot drink—any want could be attended to at once; that he sent him there to put him where he could get good bed and board." The United States Circuit Court of Appeals, Second Circuit, holds that, even if the question could be considered, as contended, as an inquiry whether the insured had been admitted to the hospital for medical treatment for disease, the uncontradicted evidence as to the circumstances under which he was taken there under advice of a physician as his patient, and the character of his occupancy, satisfied this requirement. And in view of the positive statements of the physician as to said facts the court would not have been justified in submitting the case to the jury on the theory of ambiguity or uncertainty because the witness said he sent him there simply "to get good bed and board." If this statement be not rejected as either palpably untrue or an unjustifiable conclusion of the witness, it must be so interpreted as to apply to the case of a patient who required the sort of treatment implied by better conditions, environment, and service.

7 *A Bacteriologic Study of the Intestines of Fish. Edith Loeber.

1. **Pneumonia.**—This article is an analysis of cases as regards sex, *mortality, etiology, race,* occupation, previous disorders, use of alcohol, duration, course, complications, symptoms, etc., followed by an analysis of a hundred *autopsies. The* authors find the fatality of the disease very markedly increased after the age of 40, though the number of cases is much greater in younger subjects. *It is policy, however,* to make no prognosis on youth, as the average age of the patients who died was 37.7 years, while that of those that recovered *was* 35.5, showing a much less difference than one would suppose. It would also appear from these statistics that *immigrants,* at least in the climate of Montreal, are three times as liable as natives to the disease, and that the outdoor worker is much more frequently attacked. The question of the *liability* of alcoholics to pneumonia is complicated by other questions, so that it is impossible to give positive figures. In the majority

of cases the fever rises to 102 or 104, and in quite a proportion to over 104, in the early stages. Leucocytosis occurred in 43 out of 45 cases examined, and in the 11 patients who died there were from 9,800 to 50,000 leucocytes, but in 5 of these there were severe septic complications. It would appear that the extent of the disease had much to do with the fatality; the smaller amount of lung tissue involved, the more favorable prognosis. The treatment was varied. In 40 cases there was practically no treatment. Baths were used in 45 cases; expectorants given in one-third; medicinal analgesics, heroin, etc., in a tenth of the cases; ice and heat in one-fourth; stimulants in three-fourths, and venesection was performed in only one case. There seems to be a prevailing tendency to symptomatic treatment with ready recourse to stimulants. In 60 cases where bacteriologic examinations were made, 65 per cent. showed the presence of the pneumococcus, in 5 per cent. of which it was mixed with other organisms to the extent of being a mixed infection; 20 per cent. were mixed infections of other kinds, while the streptococcus was the main agent in 8 per cent. The infrequency of the rigor at onset is also notable in this series, as also the non-enlargement of the spleen, from which it appears that pneumococcus infection is less likely to be accompanied with this complication.

2. **The Blood in Leukemia.**—Hamman reports several cases with careful blood examinations and discusses the literature. He concludes that there are three types of leukemia, each associated with a typical clinical picture. Between the blood pictures and the clinical pictures there is every grade of transition. Leukemia running an acute course is nearly always associated with the blood picture described by Fraenkel. When the blood picture described by Fraenkel is observed, it is almost certain that the case will run an acute course. The presence of either of the other typical blood pictures is an assurance—however, not absolute—that the disease will run a chronic course.

3. **Fractures of the Extremities.**—Wilbert insists on the importance of joint involvement in fractures, and says too much stress can not be laid on caution in handling of the part in case of injury near the articulating surfaces of the bone. He thinks that while it must be admitted that the Roentgen rays do not indicate the exact nature of all primary injuries, if properly used they show all serious lesions of the osseous structure and in a number of cases will indicate the nature and extent of injury to the soft parts, particularly when the lesions involve the denser portion of the tendon. Precision and exactness of diagnosis without the risk of injuring the surrounding tissue are practically impossible without the use of the *x*-rays, and without this diagnosis treatment must be uncertain. He favors the more general routine use of this method of diagnosis.

4. See abstract in The Journal of January 2, p. 53.

5. **Over-Exertion.**—Knott protests against over-strain in physical exercise and its abuse as leading to sudden and permanent breakdown in later life.

6. **Wounds.**—From an experience with over 2,000 wounds of various kinds in the last four years, Lathrop concludes that in ordinary lacerated wounds, the first thing to do is to check the hemorrhage and carefully cleanse the parts. He prefers formaldehyd soap, 10 per cent. to begin with, followed by mercuric chlorid solution and sterile water. The lacerated skin is next trimmed where necessary and the wound converted into an incised one as nearly as possible. The severed tendons are united, the edges carefully sutured, and the injured member dressed with the usual sterile gauze and cotton—dusting powder applied where desirable. A splint may be used when immobility is indicated. The dressing should not be removed for several days unless a fever gives warning of sloughing or infection. In very extensive laceration, oozing must be provided for by a drainage tube or gauze. The ordinary wounds with knives, bottles, sharp edges, etc., require little more than careful suturing and sealing with thorough asepsis. Nearly all scalp wounds of this character may be sewed up and no further trouble experienced. Domestic remedies are responsible for much of the infection. He thinks the ordinary dirty poultice is one of the most important of these. The one great agent in combating infection, preventing it when suspected and checking it, is carbolic acid. If no pus is present he would use a 5 per cent. solution. In case of suppuration he would etherize, make a free incision, use hydrogen dioxid freely and follow with sterile water or salt solution; then mop the entire cavity out with pure carbolic acid and then wash with alcohol, apply the usual dressing and insert drainage if necessary. The patients, as a rule, do well under this treatment; the spread of infection is likely to be checked. If the septic process has invaded the system, the use of antistreptococcus serum is very valuable, in full dose of 10 c.c. repeated once or twice in twenty-four hours. He used it on himself in a severe attack of blood-poisoning, and has employed it in a number of bad cases with good results. In punctured wounds with a valve-like opening the wound should be freely opened to the bottom and cleansed. In gunshot wounds of the abdomen the only thing is immediate laparotomy and suturing up of the perforation. In gunshot wounds of the extremities the Roentgen ray is of help in locating the bullet. In wounds of the chest, provide drainage and wait for Nature to cure, unless there are clear and urgent reasons for operation. The same is true in wounds of the skull and brain, with rigid asepsis and the removal of all spicules of bone.

7. **Fish Microbes.**—Loeber has studied the intestines and made cultures from the perch, bass and suckers obtained from Cayuga Lake and its tributaries. She found an abundance of microbes, chiefly the *B. proteus vulgaris*, which was present in all. The *B. coli* was not found in a single instance.

9 *The Prevailing Conception of Degeneracy and Degenerate, with a Plea for Introducing the Supplementary Terms Deviation and Deviate. G. L. Walton.
10 Cancer of the Rectum: Combined Abdominal and Perineal Operation. Charles A. Powers.

8. **Epithelioma.**—Warren describes the characteristics of the different varieties of epithelioma, the superficial types known as rodent ulcer, small-celled epithelioma and the polymorphonuclear-celled type characterized by larger cells with the characteristic nests such as are seen in cancers of the lip, back of the hand, penis, etc. The main part of his paper is devoted to the subject of rodent ulcer. He describes the process of keratosis senilis and reports a number of cases of rodent ulcer. He discusses the relative value of excision and *x*-ray therapy. In the early stages excision is advisable, but when the disease has become extensive and is rapidly spreading, the value of the *x*-ray is marked. The patient should be instructed to yield to the excision treatment, for that is possibly the best and will give reasonable prospect of permanent cure. He also pleads for a more radical operation for cancer of the lip, not only by a most liberal V-shaped incision, but the primary lesion should be dissected away in a continuous mass with the cervical glands and tissue occupying the triangle nearest the seat of growth. Incomplete, "ambulatory" operations, with cocain anesthesia, can not be too emphatically condemned.

9. **Degeneracy and Degenerate.**—Walton criticises the common use of the terms degenerate and degeneracy as signifying more than they ought in cases to which they are applied, and expressing opinions when simple facts are to be noted. Stigmata do not necessarily indicate deterioration, and it is a question whether a limited amount of them may not occur without lowering the mental or physical scale. Downward deviation is not the only type. He suggests the use of the term deviation as indicating variations from the normal, whether above or below or at the same level in the intellectual, physical, moral and other scales. It need not necessarily be limited to the lighter grades of variation. We may have the minor and major deviation, while the use of the word degeneration should be confined to marked downward tendency in the change.

15 *Public Health and Food Preservatives. (To be continued.) R. G. Eccles.
16 *Some Investigations of a Bacterial Treatment of Tuberculosis. (Continued.) Stephen J. Maher.

11. **Patented Foods.**—Halliburton notices certain common errors in regard to patented or proprietary articles of food, calling attention to the untrustworthiness of mere chemical analysis in some of these cases, and the necessity of testing both *in vitro* and *in vivo*. While, for instance, pork is the most highly nutritious of all meats, the muscle fibers are so completely enveloped in fat that a great part of it passes through the body without having been acted on by the digestive fluids. Another instance is whole wheat bread, which shows a highly proteid content, more so than the ordinary white bread, but experience shows that it is less nutritive, the material of food value being so closely invested with cellulose as to materially hinder its being acted on by the digestive fluids. Another common error which he notices is confusion of nutritious and nitrogenous foods. While the nitrogenous are indispensable, it does not follow that the non-nitrogenous foods are not also essential. For example, when the nitrogenous portion of milk is separated it is not necessarily of the same value as when contained in the milk itself. The various widely-advertised farinaceous foods, he thinks, are more harmful to the child than altered milk. The child's alimentary canal is not capable of grappling with starch and still less with cellulose. Another class of foods in regard to which the chemist can enlighten the physician is that of meat extracts, which are simply stimulants rather than nutritive in their effect. The amount of nutritive content in the small quantity given is by no means comparable to that obtained in the unaltered article. The best way to get the benefit of a steak is to eat it. The class of food products whose claim for recognition is based on their contents of the results of proteolysis, and which are presented in the form of albumoses and peptones, are of real nutritive value in proportion to the amount of albumose and peptone that they contain, and may be of use where the digestive system is at fault. Often, however, a reasonable and legitimate idea is reduced to an absurdity by ignorance, such, for instance, as "peptonized beef tea." Beef tea contains nothing capable of peptonization. Chemists, he says, can combine with medical men in enlightening the public as to the real value of foodstuffs and as to the real meaning of nutrition.

12. **Hepatic Drainage in Biliary Infection.**—Deaver discusses the condition of biliary infection, and insists that infection of the liver and its ducts can be cured by surgical means. It is nearly always accompanied with gallstone formation, and likely to become perilous from common duct obstruction. Most patients, he thinks, who suffer from cholemia really die from infection, and not from the bile retention itself. Such a patient can be saved by drainage. He offers the following conclusions as justified in the light of present experience:

1. Suppurative cholangeitis should be operated on before the infection injures the liver cells and before the retained bile has a chance to react injuriously on the general organism. The presence or absence of gallstones is of no moment in deciding for early operation, though they are usually present.
2. Cholecystostomy is the operation of choice where the lesion is acute and the gall bladder has been functionating up to the time of infection.
3. Excision of the gall bladder can safely be performed in chronic calculous cholecystitis with an obstructed cystic duct.
4. Hepatic drainage must be provided for in all cases where infection is present or suspected; either through the gall bladder or by opening the common duct or the hepatic duct.
5. Abscess of the liver is prevented and pancreatitis relieved by prompt drainage of infected bile ducts.

13. **Sterile Water Anesthesia in Rectal Diseases.**—Gant has had good effects with sterile water injections for the production of local anesthesia in operations about the rectum. The temperature of the water is unimportant, though warm is preferable as being less uncomfortable. Sterile saline solution has been recommended, but has no special advantages. The injection is made into the skin and under it, so as to produce local distension before incisions are made. If the process has been properly carried out, the skin and underlying tissue can be incised without pain in almost every instance. He recommends it for eternal cutaneous hemorrhoids and for large internal venous or capillary hemorrhoids which can be anesthetized in thirty seconds by injecting directly into the center of the large tumor sterile water enough to distend it tightly and cause it to turn white. Fissures, fistulas, ulcers, epitheliomas, strictures, etc., can be operated on under water anesthesia. A small ischiorectal abscess may be treated in the same way, but large ischiorectal abscesses, those requiring extensive cutting and curetting, had better be operated on under other methods. Prolapsus ani of a moderate degree can be almost painlessly operated on by first distending with sterile water the area of the mucous membrane and muscle structures which are to be removed, or by distending the line of incisions when a segment of the bowel is to be excised. He points out the following advantages of water anesthesia:

1. Effective local anesthesia is so quickly and easily obtained by this method, that in a majority of rectal cases there is no necessity of requiring a patient to submit to the annoyance and expense of entering a hospital and undergoing general anesthesia. For this reason it appeals strongly to the better class of patients.
2. The anesthesia instantly follows the injection of water sufficient to distend tightly the tissues to be incised or removed. This enables the operator to work quickly and, as the patient is not confined to the hospital during the after treatment, but can come to the office to be dressed, it economizes the surgeon's time and labor.
3. No annoying or dangerous complications have been observed during or following the injection of the amount of water necessary to produce anesthesia.
4. In the writer's experience the pain and bleeding following this method of local anesthetization have been less than when medicinal local anesthetics have been used.
5. It eliminates the danger to life from heart, lung and kidney complications, which are always to be feared during and following the administration of ether or chloroform, and it avoids the increased pain and hemorrhage due to straining and vomiting after general anesthesia.
6. The only requirements are a hypodermic syringe, a suitable needle and boiled water, and these are usually at hand.
7. The radical treatment of hemorrhoids can be so easily carried out under this method in the physician's office, with so little danger and inconvenience to the patient, that it should relegate to oblivion the much vaunted injection treatment, which is so dangerous and uncertain.

This method is not practicable for excision of the coccyx or extensive operations, such as are required for the removal of large tumors. The after-pain is much less than when drugs are used, since they seem to excite a state of nervous excitability and produce local irritability after the anesthetic effects have been thrown off. While the method can not be employed in all major operations, he has employed it to the exclusion of general and local medicinal anesthetics in nearly all his rectal operations, hemorrhoids, fistulas, fissures, etc., with such satisfactory results that he heartily recommends it to others.

14. **Puerperal Sepsis.**—Pryor holds that the vulva and cavum uteri contain occasional streptococci, and that these streptococci, under favorable conditions, set up virulent septic fever. Moreover, he holds that these do not stay long confined to the original locality, but penetrate the peritoneal cavity, and pelvic lymphangeitis and phlebitis are early complications. In slight cases he washes out the uterus with Thiersch's solution, then with boric acid, and packs it full with a 10 or even 20 per cent. iodoform gauze, which can be done without narcosis, producing but little pain. If the affection is superficial the amelioration of symptoms is sudden, and nothing more is needed than to remove and renew the uterine packing in three days. The second dressing is removed in two more days and is not renewed. This method is a safe one in all the milder forms of puerperal fever, whether due to cocci acting as saprophytes or to saprophytic bacilli, but if applied in the purely sapremic types, a digital exploration of the uterine cavity should be made to discover and remove fragments of placenta or membranes which so frequently are present. If this method does not succeed in six hours in controlling a case of streptococcic endometritis,

he feels sure that the germs have penetrated deeply and that we have to deal with a case of not bacteriotoxic endometritis, but of true septic endometritis or puerperal sepsis. In the latter case he would operate by incision of the posterior cul-de-sac and thorough packing around the uterus with iodized gauze, 5 per cent., so that it completely fills the pelvis from side to side and is in apposition with the posterior layers of the broad ligaments and uterus, and in contact with all that portion of the pelvic peritoneum which overlies those lymphatics and veins that carry infection. The gauze should not project from the vulva. A self-retaining catheter is inserted and cardiac stimulants employed, but, he thinks, very large doses of strychnia have a tendency to contract the arterioles, which is undesirable in streptococcic infection. The first local effect is the enormous outpouring of serum from the peritoneum; the catheter is opened every three hours, the urine measured and tested for iodin, as well as otherwise. To keep up the function of the kidneys, he gives saline enemata in eight-ounce quantities every four hours. He has never noticed iodin eruptions, but in three instances those operated on showed mild systemic effects which soon passed off. Almost immediately after the operation the temperature drops. In eight instances, and only when infusion was employed, has he noticed violent chill and great acceleration in pulse rate as the patient comes out from under ether. This is met by vigorous stimulation with brandy per rectum and nitroglycerin hypodermically. A liquid diet is allowed in twenty-four hours. Endocarditis and pneumonia are treated medicinally. In three days the uterine packing is removed, and is not renewed unless the cavum uteri is large. The cul-de-sac dressing is removed in one week and renewed. All the dressings are saved and examined bacteriologically. If a purge is employed, it should not be by calomel, but by salines, as mercury with iodin may produce poisoning. He finds the colon bacillus still present in all the dressings. It seems to be necessary only to damage the peritoneum-covered tissues very slightly to secure its presence, but he thinks it is devoid of virulence, unless associated with cocci or in the presence of greatly-damaged tissues. The idea is to kill the streptococci, and he has begun a series of observations to determine the effects of iodin on the blood, but has thus far failed to isolate it from the serum. Streptococcal infection diminishes the hemoglobin and intravenous infusion still further lowers it. In only two cases where he has tested the blood along these lines has he found the hemoglobin increased. Pryor has never been able to separate his cases into postpartum and postabortive. In his 37 operations, 36 revealed the streptococcus in the uterine scrapings. In all 37 it was secured from the cul-de-sac. In 10 cases previous curetting had been done by others, and 3 patients died. In 43 cases not previously operated on, 1 died, making a mortality of only 2 per cent. These deaths were due to bilateral pneumonia in 1 and endocarditis with pneumonia in the other 3. Six of the patients have subsequently conceived, 5 going to full term; 1 aborting at the fifth month. He compares this method of treatment with those of curetting, antistreptococcus serum, hysterectomy and the let-alone treatment, and says he has nothing to apologize for. All the women he has operated on have been spared mutilation; in 6 with full restoration of physiologic function. In no case has death resulted directly from the operation. The results, he thinks, can be accounted for in no other way than by the action of iodin.

15. **Food Preservatives.**—Eccles argues in favor of food preservatives.

16. **Tuberculosis.**—In the continuation of his article Maher first discusses the identity of the *X* bacillus according to Conn, who considers it a form closely related to the *Bacillus mycoides*. He shows how it seems to overcome in cultures the pathogenic bacilli, and gives the results of some experiments in which cultures were taken from the blood of patients before the injection of the *X* cultures and after. In the former case there was an abundant growth of staphylococci and in one case of diplococci. Following the injections, plates made under the same conditions showed scattered colon or staphylococci and the permanent growth of the *X*, which soon overwhelmed the others. In the second set of plates, made three and five days after the injection, the growth of the *X* obscured all other growths. In the third set of plates, made on the seventh day after the *X* culture injection, the growth was similar to that of the first set after the *X*.

23 Common Duct Stone Without Characteristic Symptoms. George E. Brewer.

17. **Cytodiagnosis in Nervous Diseases.**—Dana points out the value of lumbar puncture for the examination of the cell count in various cases. He has operated on 22 cases, including a number with paresis and several types of insanity, together with meningitis, tumors, etc. Marked lymphocytosis seemed to be the rule in paresis, though in two of his cases no cells were found. In the alcoholic psychoses there were either no cells found or only three to six in one hundred fields. In a case of cerebellar tumor and one of hydrocephalus there were no cells, and in a case of contusion of the brain the prognosis was considered serious on clinical grounds and confirmed by cell count. He thinks the method will be of use in diagnosticating the doubtful cases of paresis and tabes in the early stage, and also in determining whether or not the patient has had syphilis and whether certain symptoms indicating invasion of the central nervous system by this infection are correct. It will also hold good in diagnosing the activity of the process. If there is an actual inflammatory change going on it will be shown by the presence of polynuclear leucocytes, while in the ordinary conditions of specific infection, only mononuclears are present with a proportion of not over 5 per cent. of polynuclears. He has had no serious trouble from this method, though the operation is somewhat disagreeable as regards subsequent headache and vertigo. It seems in some cases that the headache is reflex or psychic.

The technic of the method is described in detail by Dr. Hastings.

18. **Lymphocytosis of the Cerebrospinal Fluid.**—This article is in a measure supplementary to Dana's, and the findings are practically the same.

19. **Radioactive Treatment with Thorium.**—Tracy illustrates the radio-activity of thorium and calls attention to its antifermentative property. He suggests two methods of using radio-activity in tuberculosis. One is by using a saturated solution of nitrate of thorium in a large shallow receptacle. A slight current of air can be caused to pass over the solution from a compressed air tank, while the patient is inhaling. With the nitrate of thorium there may be more or less free nitric acid; this must be neutralized by passing the emanations, before inhalation, through a wash-bottle containing a saturated solution of sodium bicarbonate. The more satisfactory way, he thinks, is by heating the oxid of thorium by the Lieber apparatus, which is illustrated. The procedure leaves in the lung cells a fine film of radio-active matter which in turn produces the phenomenon of induced radio-activity in the same parts, which may last for one or two days. This is shown by the patient, after inhaling thorium emanations, exhaling on a photographic plate, which produces the ordinary effects on the silver salts. An inhalation given every day or every other day, he says, will keep the lung cells constantly in a radio-active and antiseptic condition. The heat emanating from a Lieber apparatus can be cooled by passing through a glass and rubber tubing, and the inhalation may be given for a period of fifteen minutes at the outset, gradually increasing to half an hour. This method of treating tuberculosis will not interfere with other medical, dietetic or other treatment.

21. **Abdominal Operations.**—The importance of early operation in abdominal troubles is pointed out by Pond. He would fix no stated time. In one case, perhaps, twelve hours is late; in another three days is early. Among those demanding earliest interference are irritations of the stomach, intestines and gall bladder. Another misdirected idea is that of interval operation for appendicitis. Of course, the mortality of operations in the interval is very small, but when to this is added those that die during the attack not operated on, it becomes much larger. It is not always possible to diagnose cases positively at once, but by grouping of the symptoms and exclusion, we can decide whether it is safe to wait or operate at once. In conclusion, he says if you wish to do right by your patients, operate early; if you wish to be conservative and have a small death rate, operate early, and if you wish to get a medical reputation and help the cause along, do the same.

27 *The Pathology and Treatment of Osteoarthritis. Edward M. Merrins.
28 *Bovine Tuberculosis. J. W. Kime.
29 Neurasthenia. Joseph N. Study.

25. **Ringworm.**—The danger of the transmission of ringworm from one patient to another and also through domestic animals is remarked on by Beadles. He urges the necessity of school inspection and the comparative isolation of the sufferers, not allowing them to use the same towels, combs or brushes with others, and frequently sterilizing those that are used. The number of domestic pets, especially those that are mangy or diseased, should be diminished.

26. **Cryoscopy.**—Burthe's article on Claude and Balthazard's method does not permit of abstracting in detail, and should be referred to directly.

27. **Osteoarthritis.**—Merrins sums up the etiology of the disease, as whenever the tissues or joints suffer from some low form of chronic inflammation from some disease or injury, or are kept continuously irritated from overstrain or foreign bodies, or nutrition is impaired by some glandular disturbance, osteoarthritis may occur. He would not say that it is altogether a disease of toxic origin, but remarks that it is in those diseases in which toxins are formed abundantly that we may expect to find osteoarthritis, and do most frequently. He does not consider it a primary, but rather a secondary affection of these conditions. The medical treatment is that appropriate for the primary condition. The alkalies are prescribed, and do good by preventing intestinal fermentation, but it is doubtful if they combine with the uric acid in the human body as in the chemical laboratory. If they do, they are useful only where the gouty diathesis exists. The salicylates may be given in rheumatic cases for the relief of pain. Except the specific treatment in syphilitic cases, no drug he is aware of is capable of reducing the enlarged bones, but much can be done to check their growth, especially where the internal glandular secretions are defective, by giving preparations of the gland which is at fault. The antidiabetic régime has been found advantageous by Bezley Thorne, and change of climate is often beneficial, and treatment at thermal springs health resorts may improve the general condition. For local treatment, after acute inflammation has subsided, he would give baths of superheated dry air, followed by gentle passive movements and massage, gradually increasing the range of motion, but never causing severe pain or inflammation. In the early stages rest and alleviation of pain are necessary. In advanced cases forcible manipulation of the joint under anesthesia has occasionally effected temporary improvement, but is hardly advisable.

28. **Bovine Tuberculosis.**—Kime insists on the dangers of infected milk and the need of elimination of tuberculous animals from the dairy herds. He thinks the unfortunate utterances of Koch have materially lengthened the time necessary to stamp out bovine tuberculosis.

### St. Louis Medical Review.

*January 23.*

30 *Preparation of Patient for Abdominal Section and Treatment of the Case. Walter B. Dorsett.

30. **Abdominal Operations.**—The preparation of the patient for an abdominal operation is described by Dorsett. He believes in the simpler methods, avoiding irritant chemicals around the field of operation, but using good, clean soap and hot water and a razor to scrape off any excretions that are brought to the surface. This may be all that is necessary until the patient is brought to the table, the part being protected by a thick layer of sterile gauze or absorbent cotton left in place until the patient is anesthetized and brought to the operating room. This is then removed, and the site of operation again scrubbed or wiped off with a solution of green soap, rinsed off with sterile water, after which sulphuric ether is applied, and when it has disappeared by evaporation, alcohol is used. Sterile towels are applied around the proposed incision, care being taken not to leave too great a portion uncovered. During the operation the surgeon should avoid touching the skin of the patient unnecessarily, and at no time, if the intestines be brought through, should they be allowed to rest on the skin, but only on sterile towels, which should be changed as soon as soiled. He thinks, in our zeal to get the intestinal tract free of fecal matter, we overdo catharsis and weaken the patient. His favorite formula for all celiotomies is: Magnesium sulphate, 3 drams; sol. magnesium citrate, 12 ounces; solution carmin, 15 minims. Sig.: One-third contents of bottle every three or four hours till bowels act. On the morning of the operation a copious soapsuds enema is given to remove the remaining fecal matter, so that in case a saline enema be required later a better absorbing surface in the colon is provided. For the prevention of emesis he has lately established the plan of allowing the patient to drink thirty to forty ounces of water in quantities of ten ounces at intervals of half an hour, prior to going to the operating room. The stomach is then filled with water, and when the chloroform or ether enters it dissolves in the water and is held in solution, avoiding irritation of the gastric walls. The last drink of ten ounces is given immediately before the anesthesia. He has noticed that in most instances this last portion is vomited with but little effort and the nausea ceases. This practice has greatly lessened his anxiety in many cases. For dressing the incision he is in the habit of folding pads of gauze so as to make them hard, applying them on each side of and over the line of incision, maintaining them in contact with the abdominal wall by a larger piece of gauze sealed down with collodion. This firm dressing, when the binder is drawn snugly, acts as a buffer or in the same manner as does a pad or truss. The collodion also prevents the dressing from slipping off during convalescence or when the patient turns. It is not removed until the tenth day after the operation, when the pads are removed. For gaseous distension he uses the Virgil O. Hardin treatment, viz., enemata of alum solution, half an ounce of pulverized alum to one pint of warm water, carried well up into the colon, best introduced with the patient in the Sims posture. The peristalsis of the colon thus induced draws the gas through the ileocecal opening, and it is expelled. He prefers this to any attempt to open the bowels with laxatives the day after the operation.

40 Some Observations of Practical Interest on Colonic Lavage. Milton H. Mack

34. **Suppurative Ear Diseases.**—Beck describes the method of treating suppurative ear disease by means of a specially adapted probe and tube containing gauze. The tube has a little beak at the tip which acts as a retractor for the tragus and also aids the probe in getting hold of the gauze. His conclusions are given as follows:

1. That most individuals afflicted with suppurative ear diseases belong to the poorer (clinically treated) cases 2 That two or three times a week treatment by the physician is not satisfactory, especially in acute cases 3 That the constant moisture in the middle ear and external ear leads to granulation formation, decomposition and necrosis 4 That by means of intelligently instructing patients the treatment of suppurative ears can be markedly improved on and better results obtained 5 Patients and their immediate friends are easily instructed 6 That by means of this specially contrived tube gauze and probe the patient may be safely intrusted with the treatment, since infection and injury are not liable to follow. 7. Without the aid of a head mirror, ear speculum, etc, one can pack the ear very easily in that way, and it makes a very convenient appliance also in office practice

35. **Urethritis.**—Rubin uses a weak permanganate of potash solution for irrigation, starting with 1 in 10,000 or 1 in 15,000, gradually bringing it up to 1 in 5,000 in the third or fourth week. He uses the ordinary fountain syringe and a glass bulb, olive-shaped, the same as used for the nasal douche. He prefers a single current, and treats the acute case once a day. During the first two weeks the anterior urethra alone is irrigated, but later the posterior urethra and bladder are also flooded. With the irrigation treatment he also has the patient use 5 per cent. argyrol solution as an adjunct, and also prescribes sandalwood oil, 5 minims, with salol and sodium bicarbonate to be taken 3 gr. each one or two hours after meals These remedies are only necessary in the acute or subacute form when the urine is highly acid He allows the patient to drink plenty of pure water, discontinuing, of course, all carbonated waters and alcohol. In chronic cases the sound plays an important part in addition to the irrigation treatment, but the irrigation precedes all the instrumental work. He calls attention to the value of cocain solution, 2 to 5 per cent, used before introducing the sound in very sensitive urethras His cases were cured in three to six months, three treatments a week being sufficient for the chronic cases He has no good word to say for the instillation method

38. **Blood Examinations**—Whitman's article is a clear account of the method of examining the blood and the use of various reagents He thinks, however, that the physician should read some special work on the subject While the technic may look a little intricate to the beginner, two or three hours' practice will go far to solve its difficulties. The examination does not take any length of time

42 *The Present Status of the Treatment of Mastoiditis Geo F. Keiper
43 *Chronic Tonsillitis Gilbert D Murray.
44 The Present Status of the Dunbar Hay Fever Therapy. F W Bailey

42 **Mastoiditis.**—Keiper has sought the opinions of various authorities as to the use of heat or cold and the methods of application in mastoiditis, and gives the results of his replies. The author himself favors the use of hot applications, and that seems to be the opinion of the majority, at least for continued applications.

43 **Tonsillitis.**—Emphasis is laid by Murray on the following points

1 The teeth should receive attention from infancy The tongue when coated should be cleansed as carefully as the teeth 2 The mouth is a primary cause of tonsillitis and ought to receive simultaneous treatment with the throat 3 Offensive breath, from microorganisms present in the mouth and throat, can be eliminated through the personal effort of the patient 4 Bad taste in the mouth, particularly before meals, suggests infection of the tonsils, decomposing epithelium debris on the tongue, gums, teeth and oropharynx—one or all This filth (in which Steinberg found 42 different varieties of micro organisms) ought to be cleaned and sterilized several times daily by the patient 5 Diseased tonsils, not necessarily enlarged and often hidden, no longer act as a barrier to disease, but rather as a germ incubator and ought to be removed 6 No method of removing the tonsil is a safeguard against dangerous hemorrhage when one operates on a bleeder

59 Cysts of the Mesentery. Alvah H. Traver.

48. **Myasthenia Gravis.**—Hun's patient was a man 32 years of age, the disorder commencing insidiously, first showing itself in ptosis, with the slow development of the typical clinical picture of the disease, which is remarkably uniform in its manifestations. The postmortem revealed a sarcoma of the anterior mediastinum, possibly originating in the thymus, but no lesions in any part of the nervous system. In the presence of sarcoma the case was similar to one of Weigert and also one of Link in which the thymus was persistent. In Oppenheim's case of doubtful diagnosis, but closely resembling myasthenia gravis, there was also sarcoma in the anterior mediastinum. The authors, however, do not attribute the condition to this anomaly. They conclude that so far as can be estimated from the present data, the best theory of the pathology is that of interference with the lymph circulation. The only lesion that has yet been found which has been confirmed by a number of observers is infiltration of the muscles with lymphoid cells. Whether this is primarily due to irritation of a toxin or some other cause, or whether it is secondary to primary change in the lymphatic circulation, is uncertain, but Hun inclines to the former. The prognosis of the condition is necessarily bad, and the treatment, as the authors say, is a matter of the future. The article concludes with a full bibliography.

49. **Landry's Paralysis.**—Gordinier reports two cases, one with recovery.

50. **Diphtheria Antitoxin.**—Craig's report is based on a study of 1,182 cases. His conclusions are given as follows:

1 The use of antitoxin is increasing and is generally accepted as a valuable therapeutic agent by the medical profession 2 The medical profession is using mature judgment in the selection of cases for the use of antitoxin, the milder cases being permitted to to go on to recovery without the use of antitoxin, and the more severe cases, including the mixed infections, are given the benefit of protective inoculation 3 The use of antitoxin has decidedly diminished the death rate and has saved many lives

52 This article appeared elsewhere. See THE JOURNAL of Jan. 9, ¶33, p 127.

53. **Menstruation.**—The changes in the endometrium in menstruation are summed up by Lipes in substance as follows: The menstrual cycle is divided into three periods, one preceding the flow, characterized by a gradually developing congestion resulting in serous or serosanguineous infiltration of the stroma of the mucosa, separating the cellular elements and gravitating toward the periphery, forming collections of blood beneath the surface epithelium. Slight glandular hypertrophy, as well as swelling of the gland cells and consequent hypertrophy of the whole mucosa, likewise occur. The second stage of active hemorrhage is characterized by the outflow of blood through a diapedesis or through a rupture of the subepithelial hematoma with more or less loss of superficial epithelium depending largely on the severity of the

process. In the third stage involution takes place. The engorgement lessens, and rapid absorption of the blood in the stroma takes place. The epithelium which has been lost is regenerated by indirect cell division of the adjacent cells. This stage is prolonged until the premenstrual swelling takes place again, or else there is a slight interval during which the mucosa is inactive.

54. **Tetanus.**—Elting reports three cases and reviews the pathology and treatment. He concludes that the transmission of the toxin is along the axons of the peripheral nerves and not along the perineural and endoneural lymphoid spaces, and that it has a special affinity for the anterior horn cells and their analogues, the motor nuclei of the medulla and pons, as well as the peripheral and central axons. The sensory impulses play an important part in the production of this tetanus spasm. The action of tetanus toxin on the nerve cell is, perhaps, best explained by Ehrlich's theory, according to which the protoplasm of the nerve cell possesses certain so-called side chains which are able to attract and attach themselves to tetanus toxins in the blood. He favors the antitoxin treatment, and in this the subcutaneous method will be most generally applicable, but should be supplemented in severe cases by subdural injections. The Baccelli method of use of carbolic acid, he thinks, perhaps, is of value as a symptomatic treatment in conjunction with antitoxin.

56. **Ozena and Tuberculosis.**—Theisen has studied the connection of ozena with tuberculosis, observing altogether 21 cases, in 8 of which pulmonary tuberculosis occurred. He thinks it is more than a coincidence that this complication should be so frequent. When we consider how ozena affects the normal functions of the nose, we can readily understand how the tendency to tuberculosis can be established.

57. **Starch Digestion in Infancy.**—From a series of tests made on babies in a hospital Shaw concludes that:

> The saliva of very young infants contains a diastatic enzyme capable of converting small amounts of starch into maltose. This diastatic action of the saliva may continue in the stomach as long as two hours after feeding. Therefore, on physiological grounds, there is no reason why young infants can not digest small amounts of starch.

65 The Value and Limitation of Crounotherapy (mineral waters). George T. Palmer.

60. **Rectal Incontinence.**—Pennington operates by making a semicircular incision at one side of the anus, cutting the sphincter muscle and freshening the edges or ends of the torn sphincter by taking a V-shaped piece out of the angle and suturing the parts together. Then the flap is replaced and sutured and an aseptic dressing and T bandage applied. He thinks Chetwood's operation (see The Journal of April 19, 1902, vol. xxxviii, ¶30, p. 1037), is also a valuable one, and describes it. The article has 6 illustrations.

71 *On a New Symptom of Hemoglobinuria; Cyanosis and Gangrene of the External Ear. F. Rohrer.

67.—This article has appeared elsewhere. See The Journal of Jan. 9, ¶19. p. 125.

69. **Bone Necrosis in Chronic Purulent Otitis.**—Scheibe finds that necrosis in chronic non-specific middle-ear suppurations is exclusively of local nature. The suppuration acts in a necrotic manner only when pus is retained and putrefies. This condition generally occurs only when the middle-ear suppuration is complicated by cholesteatoma, although other causes are possible. In one patient the bone necrosis followed the use of carbolic acid. It is striking how rarely chronic suppuration without cholesteatoma causes necrosis. The prophylaxis, therefore, is connected with the treatment of the cholesteatoma; if it is possible to prevent putrefaction of pus, the onset of necrosis can be prevented. This is usually accomplished by antiseptic treatment with the tympanic canula as devised by Hartmann and Bezold. In exceptional cases, where continued treatment does not succeed in correcting the fetor, operation is indicated. He has not, however, observed a single case of cholesteatoma where necrosis occurred during treatment.

70. **Traumatic Hysterical Deafness.**—Barth reports two cases in which, with complete bilateral deafness of hysterical origin, the unconscious perception of musical sounds was not impaired. In the first case the condition was only temporary. In the second case with a traumatic cause in a rather neurotic individual, the deafness persisted and color blindness also appeared; the progressive course of the disease made the prognosis unfavorable.

71. **Hemoglobinuria.**—Rohrer reports a case where, with hemoglobinuria there was a bluish black discoloration of the auricles and superficial gangrene which, however, passed away without leaving a serious scar. The urine contained albumin and blood pigments. He has not observed this symptom in otologic literature. but found a case published by Wilkes in 1879, in which a similar symptom was associated with abscess of the hip-joint after injury. The fingers in this case, the toes and the tip of the nose also participated. (This is reported here as a case of hemoglobinuria, though in the brief abstract given, this symptom is not mentioned). These observations, Rohrer remarks, show that, with the appearance of lividity and cyanosis, hemoglobinuria should be suspected and an analysis of the urine be made.

72 *Do We Place Too High a Value on the Presence or Absence of Murmurs in Cardiac Disease? E. G. Wood.
73 *Fractures of the Skull. Paul F. Eve.
74 The Finsen Light Cure. H. John Stewart.

72. **Cardiac Murmurs.**—The diagnostic value of murmurs is over-estimated in Wood's opinion. He does not think that murmur in the cardiac area is conclusive evidence of heart disease. It may be hemic or exocardial in origin, and even when endocardial, it is doubtful whether it gives any information as to the condition of the cardiac muscle or the extent of the valvular lesion. In most cases changes in the size of the heart, character and relative intensity of the cardiac sounds and the condition of the pulmonary or peripheral circulation are the most important factors in the case. The absence of cardiac murmurs is of very slight value in excluding cardiac disease, as they may be absent in grave disorders for a long period. In prognosis they are also of very little value. We can rely more on the general appearance of the patient and the same indications as in diagnosis.

73. **Fractures of the Skull.**—Two cases are reported by Eve, who thinks that in all cases of injury of the cranial vault or where there is any suspicion of fracture, it is the duty of every surgeon to cut down and investigate. If there should be a small external wound it should be enlarged. If there is a fracture, whether linear or otherwise, trephining should be performed as soon as possible on account of the danger from sepsis. He believes in thorough irrigation with normal saline solution, continuing it from ten to twenty minutes, and where any spiculæ of bone are carried into the brain, this irrigation should be carried to the very bottom of the wound. There should also be drainage by either catgut, gauze or tube, but it can be dispensed with if no pus is found at the end of the third day. The hemorrhage can be arrested by hot normal saline solution

(120 F.) or gauze pack. In fractures of the base of the skull he thinks sepsis can be prevented by thorough irrigation with warm normal saline solution, 115 to 120 degrees, either in the nasal cavity or ear, as these are the points where the bacteria usually gain access. It has been his plan for years to irrigate these cavities as far as possible and continue it from ten to twenty minutes. Strychnin should be administered for combating shock and the bromids to rest the brain, preferably the bromid of ammonium. He lays stress on the position of the patient, having those with fracture of the anterior fossæ lie on the abdomen, while those with fracture of the middle or posterior fossæ lie on the ear from which the bleeding occurs. The irrigation in these cases should be done every two or three hours, as gently as possible.

76 *A Study of Actinomyces Cultivated from Commercial Vaccine Virus. William T. Howard, Jr.
77 The Shape of the Mammalian Red Blood Corpuscles. Frederic T. Lewis.

75.—See abstract in THE JOURNAL, Jan. 2, 1904, p. 52.

76. **Actinomyces.**—Howard describes here the forms observed by him in vaccine virus. Actinomyces have been found in bovine vaccine virus by three sets of workers, Sabrazes and Jolly, Folli, and himself. His summary is as follows:

> The vaccine virus of five vaccine establishments in the United States examined by me during the period from October, 1902, to May, 1903, contained [illegible] a total of ninety-five cultures. I [illegible] nine different species of actinom[illegible] new, were found. These organisms probably reach the virus from the air, water, soil, hay, straw and hide. While unsupported by bacteriologic investigations, or by experiments, it is not improbable that some of the postvaccinal suppurative infections are caused by these organisms, and are cases of atypical actinomycosis.

79 The Regular or Rational Physician. S. B. Kirkpatrick.
80 Puerperal Infection. J. M. McCutcheon.
81 Report of Two Cases of Tubo-ovarian Pregnancy. R. M. Dunn.

78. **Urethral Stricture.**—Guinn advocates the electrolytic treatment, using a battery of ten cells or more, an indifferent electrode pad and a series of olive-pointed bougies, of different sizes. He commences with the smaller size first, with a current of three to five milliampères for fifteen minutes, repeating the operation after ten days, using each time a larger electrode sound, always with the negative pole in the stricture. This softens and dissolves away the tissue, while the positive pole hardens and dries. The latter is attached to the indifferent pad electrode, placed at some indifferent point on the body.

87 Erysipelas and Atrophic Rhinitis. I. Valentine Levi.

82. **Hydrophobia.**—Illman reports a case carefully observed throughout its course, and followed by autopsy. He calls special attention to the lack of psychic manifestations. Inoculation experiments were positive in rabbits.

84. **Myxedema and Diabetes.**—The cases here reported were of brothers, aged respectively three, four and one-half years, and in each case there was a marked diabetes, not simply glycosuria. The occurrence in such early childhood is of note, as also the relationship of the patients as indicating a degenerative hereditary tendency. Both cases were favorably affected by thyroid medication. Its action on both the conditions was notable, and it was even earlier in its effect on the diabetes than on the myxedema. There was without question, he thinks, from this fact, a direct relationship between the diabetes and the thyroid gland. The fact, too, that the prognosis of diabetes in children has generally been unfavorable, while in these cases it was the reverse, is worth mentioning. He asks, does not the outcome in this case indicate that diabetes due to deficient thyroid function is far less grave a type than that caused directly by destruction or pathologic conditions of the islands of Langerhans?

86. **Hay Fever.**—Somers notices Dunbar's work on this subject and gives his own experience with the use of serum from animals inoculated with the pollen toxin of golden rod in ten cases. Admitting that the number is too small for positive conclusions, he suggests that the experience obtained with the golden-rod antitoxin indicates that:

> 1. The serum produces prompt and positive amelioration of the symptoms of fall hay fever in the majority of cases. 2. In a smaller number this favorable result is soon accompanied with the complete disappearance of the affection. 3. Where slight or no action is seen after its use, pollen as an etiologic factor does not predominate. 4. When results are obtained, it favorably influences all the manifestations of hay fever. 5. While I am unable to state from personal experience the effect of the serum on hay fever occurring at other times of the year, or its effects when administered in advance of the attack, yet when given during the attack, irrespective of its severity, it produces marked palliation rather than absolute cure. 6. Its effects on future attacks remain as yet unknown. 7. The serum in powder form is slightly soothing to the nasal mucosa, has but little influence on the other symptoms of the affection, and in occasional cases it may act as a direct irritant. Finally, as a result of larger experience, especially with hay fever occurring at other times of the year, it may become necessary to modify some of the opinions in regard to this antitoxin.

88 *The Question of Nasal Treatment for the Cure of Diseases of the Ear. Alex. W. Stirling.
89 *Combined Anesthesia with Ethyl Chloride and Ether. William P. Nicholson.

88. **Nasal Treatment of Ear Diseases.**—The proposition advanced by Stirling is that it is of no use to employ intranasal treatment for the relief of deafness unless such treatment is also advisable for the sake of the nose itself. In a few cases, however, of slight adenoids around the orifice of the eustachian tube and associated with middle-ear catarrh, it would be advisable to remove them even if there were no symptoms referable to the nasopharynx.

89. **Ethyl Chlorid and Ether.**—Nicholson, advocates ethyl chlorid as a preliminary to ether anesthesia, using an ordinary Esmarch chloroform inhaler and spraying from an ordinary kelene tube. When the patient ceases to show pain from pinching the skin of the hand, the ether inhaler is applied and the patient passes rapidly into complete anesthesia in from three to five minutes. The advantages of this method are the lack of struggling, the absence of prolonged nausea of anesthesia, and the very small amount of ether consumed. He thinks the method is as free from danger as any anesthesia can be, is inexpensive, and lessens to a large degree the danger of complications. It requires no such cumbrous apparatus as the nitrous oxid ether anesthesia.

**1, 3 and 4. Foreign Bodies in the Bronchi.**—Lermoyez describes the history of a prune stone which entered the air passages during a fit of coughing. The subject was a healthy young woman, *but all attempts to remove the stone through* the natural routes or a tracheotomy incision proved fruitless, and she died in a few days with symptoms of bronchopneumonia. He had the impression that his intervention had aided in the impaction of the foreign body and the fatal result. In contrast to this occurrence several years ago, he relates the history of a tack slipping into the bronchi recently *in the same way. He was able to locate it exactly with* radioscopy, examine it through the bronchoscope, and he might have withdrawn it by the natural route with a magnet if he had had one of the proper shape. As it was, low bronchoscopy through a tracheotomy incision, followed by the application of the magnet, resulted in the immediate withdrawal of the tack. A foreign body not attracted by the magnet could have been readily removed with forceps under the same conditions. He lauds the great value of Killian's bronchoscope as "lifting the veil that has hitherto concealed the bronchi from our view." Béclère gives a number of radiograms of foreign bodies in the bronchi and emphasizes the superiority of radioscopy to radiography for these cases. The former shows whether the foreign body is loose or impacted. When a radiogram is taken it should be during apnea, as he shows by comparison of the results thus obtained. Guisez describes the technic of bronchoscopy with numerous cuts, including one of a phantom bronchus for practice.

**5. Tuberculosis in the French Army.**—De Lavarenne confirms the recent assertions of the medical members of the French parliament in regard to the dissemination of tuberculosis throughout the farms and villages by returned soldiers. The removal from a country life to the barracks and the stress of military life are liable to fan a latent tuberculous affection into a blaze, and large numbers of the recruits develop serious tuberculosis during their first year of compulsory military service. *When dismissed,* they return home to become a focus of infection for the farm or village. Even during their term of service they are liable to infect other healthy recruits. He states that the candidates are examined with such haste that less than thirty seconds was devoted to each one in the last examinations at the recruiting office for the Seine department. It follows that many really healthy young men are rejected while others are accepted when a more careful examination would have revealed incipient or latent tuberculosis. Country physicians say that the proportion of tuberculous patients is constantly *increasing* in their practice where formerly they were rare. Some have now from 20 to 30 per cent., and one reports 60 to 70 per cent.

**6. Diagnosis of Pyelitis and Pyelonephritis.**—Bazy mentions that when *inflammation* of the lower part of the ureter is determined we may safely assume total ureteritis and pyelitis, as a circumscribed ureteritis has never been known to date. Pyelitis or pyelonephritis may exist without the classic symptoms, and the functional signs, pollakiuria and terminal pain or *hematuria at micturition* may be ascribed to a real or imaginary cystitis Abnormal frequency of micturition at night in comparison to the day should arouse attention, whether the abnormality is in a greater or lesser frequency than the daytime desires in comparison to normal Another sign is the presence of pus in too large proportions to be ascribed to the bladder alone, a deposit of 1 5 to 2 cm at the bottom of the vessel Pyelitis and pyelonephritis may induce pain on pressure of a point on a horizontal line passing through the umbilicus at a short distance from the latter, almost exactly over the outer margin of the rectus muscle He calls this tenderness the paraumbilical or upper ureter pain Another painful point is just below the costal arch, another at the apex of the costomuscular angle The latter is the lumbar pain The first, the paraumbilical, is the most frequent, the most painful, and frequently appears alone Pressure at this point is sometimes more painful than on the kidney itself, and sometimes induces a desire to urinate He calls this the pyelovesical reflex It is impossible or difficult to palpate the ureter through the vagina in health, but in case of inflammation it can be felt as a cord, more or less tender its entire extent and especially at its orifice in the bladder Pressure at the latter point is sometimes accompanied by a desire to urinate and sometimes by an ascending pain felt in the corresponding lumbar region This latter pain is characteristic and suffices alone to establish the diagnosis of pyelitis even when the ureter is not directly palpable In the male subject the same kind of pain is induced by pressure on the fundus of the bladder just above one of the horns of the prostate Palpation through the rectum in the male subject is thus almost as instructive as through the vagina in the female In case of bilateral kidney affections the upper and the lower ureter pains are sometimes crossed in respect to their intensity In conclusion, he insists on the value of nocturnal pollakiuria as the most important of all signs for the differentiation of pyelitis In treatment, a milk diet and rest are the most important and most efficient measures at our command, and usually suffice in recent cases

7 **Growth Energy**—Trémolières thinks that the day is at hand when we will be able to estimate the energy of growth just as we now estimate the energy of heat, light, mechanical force and electricity The phenomena of growth evidently depend on the materials of cell nutrition, lecithin, salts, etc, supplied in the food, dissolved in the water the organism absorbs, and penetrating into the cells by the processes of osmosis, under the influence of the organic electricity Growth energy is a colossal force, as we see solid rocks split by the growth of the roots that have penetrated into their interstices When we are able to measure it and know more about it we may be able to stimulate the development of the human body or correct its growth when it is arrested or abnormal

8 **Balsam of Peru Treatment of Compound Fractures.**—During the last four years van Stockum of Rotterdam has treated as follows all of the compound fractures at the city hospital, of which he is the surgeon in chief All foreign substances are removed with sterile forceps, but the wound is not washed nor disinfected, and no ligature is applied unless a large artery is bleeding Balsam of Peru is then poured copiously into the wound, its penetration promoted by moving the limb a little The fracture is then reduced as if it were a simple fracture, and the wound is dressed with gauze impregnated with the balsam under an impermeable covering The limb is then immobilized in a plaster cast for three weeks, the dressing left undisturbed The temperature always rises at first, but not seriously, and subsides to normal by the fifth or sixth day At the end of the three weeks the mortified tissues are found mummified, the edges of the wound show no trace of redness nor swelling, the bones are found consolidating, and the wound granulating normally He seldom had occasion to apply the balsam more than once or twice in 90 cases thus treated, including 58 of the legs, 4 of the thigh, 15 of the arm, 2 of the pelvis, 1 of the patella, 2 of the calcaneum, and 8 of the lower jaw The treatment was a complete success in all but 4 cases In these there was some suppuration, but all recovered without a second operation except in one case, in which gas gangrene necessitated secondary amputation In 8 cases healing was delayed by the presence of a foreign body, causing a fistula, and requiring removal The effects of this treatment can not be due to any bactericidal effect of the balsam, but rather to its action in stimulating the living tissues They corroborate those obtained by Landerer in tuberculosis with cinnamic acid, one of the elements of Peru balsam

9 **Effects of Tuberculin Injected Immediately After Tuberculous Infection**—Marmorek attributes the effect of tuberculin to its action on the tubercle bacillus itself, not on the lesions it induces He believes that tuberculin in contact with the bacilli causes them to secrete an entirely different toxin which is responsible for the febrile reaction observed He has found it possible to induce this reaction by injecting tuberculin a few minutes after inoculating guinea pigs with tubercle bacilli Twenty hours after the inoculation there is no reaction to the tuberculin, probably because by this time the bacilli have been taken up by the phagocytes The reaction occurs again, however, after sufficient time has elapsed for the bacilli to regain their liberty by destroying the phagocytes in which they were enclosed

10 **Direct Examination of False Membranes**—Deguy and Patry affirm that the method of examination described has seemed to them in many cases more rapid and more exact than diagnosis from cultures The fibrin is dissolved out, and nothing is left but the stained microbes, grouped as they have been in the false membrane A scrap not larger than 1 to 5 mm of the false membrane, as thin as possible, is rinsed in distilled and sterilized water It is then stained with a mixture of 30 c c of an alcoholic solution of methylene blue and 01 c c of potassium in 100 c c of water It is left in contact with this solution for ten to fifteen minutes, and then rinsed again in distilled water, dried with blotting paper, and a drop of a 1/20 solution of potassium is placed on it and left in contact for twenty to thirty minutes The excess of fluid is removed with the edge of a piece of blotting paper, and then a drop of potassium silicate is placed on the specimen Another strip of glass is then placed over it and the whole is compressed by applying a weight or squeezing with forceps while the silicate is dried for ten minutes in an incubator The two glasses are then firmly glued together and the specimen is ready for inspection

12 **Surgical Treatment of Typhoidal Perforation of the Bowel**—Cazin has been able to find on record 358 cases of perforation of the bowel in typhoid fever in which operation was performed The list includes one from his own experience and Keen's 158, as also the statistics of Mauger, Cariès, Junqua, Pédarré and Elsberg Of the entire number, 107 of the patients recovered, a proportion of 29 88 per cent Only 49 of the entire list were reported in France, the recoveries numbering 9 He pays tribute to the Americans as the leaders in this line He regards leucocytosis as of secondary importance for the diagnosis, as it is inconstant and tardy The hour of the intervention was mentioned in only 48 of the series of 63 successful cases, dropping all the incomplete and dubious records In 38 of this 48 the operation was undertaken within twenty four hours of the perforation, and only in 10 later than this One recovery is reported by Cardi with an interval of forty eight hours The patient was a girl of 13 with diffuse peritonitis following a typhoidal perforation about 10 cm from the ileocecal valve Depage has also reported the recovery of a woman of 42 operated on three days after the perforation He cut a V out of the intestine and closed the wound in the intestine with a suture in two

tiers. To relieve the distended intestine he made several capillary punctures, and the patient, whose condition had been desperate, recovered complete health. Ether or chloroform has generally been preferred to local anesthesia, and a very small amount proved sufficient for the purpose. The perforation was usually found in the last 50 cm. of the ileum, more rarely in the appendix, colon or cecum. In the 219 cases in which the site was mentioned, the laparotomy was lateral in 123 and on the median line in 90. A Lembert suture with silk was the general choice. Catgut is absorbed too readily, and in a few cases when it was used the suture gave way. Certain surgeons have freshened the edges of the perforation or resected the ulcerated zone, but Cazin does not regard this as essential, and it merely prolongs the operation. Owing to the friability of the coats of the intestine it is wise to take the suture through a fold, some distance from the edge of the perforation. Two rows of sutures with separate stitches will generally ensure the closure of the perforation. In one case Legueu utilized a piece of omentum to patch the hole with. A stercoral fistula developed the fifth day, but it healed spontaneously by the twentieth day and recovery was complete. Escher advocates suturing the lips of the perforation to the abdominal incision, to prevent danger of occlusion from paralysis of the intestines. Cazin thinks that the successes obtained by suturing the perforation at once render this procedure superfluous. In case the ulcerated zone threatens further perforations he would pack strips of gauze around it to wall off infection from the abdominal cavity in case further perforation should occur, rather than to inflict such a serious operation as resection of the bowel on the enfeebled patient. Leconte thus packed a case with several suspicious points, and thirty-six hours later a large mass of pus and feces was evacuated. The patient recovered and the fistula closed spontaneously in four weeks. When the peritonitis is already diffuse—as it generally is—the abdominal cavity should be copiously rinsed with hot saline solution. This indication is one of the reasons why general anesthesia is preferable. Multiple and efficient drainage should not be neglected.

13. **Treatment of Muco-Bloody Colitis or the False Dysentery of the Tropics.**—Blanc writes from Shanghai and describes the treatment which he has found most effectual for the diarrheic sickness which he calls false dysentery: Castor oil in the morning, no food until evening, when a soft-boiled egg or chicken broth is allowed, and at bedtime a goblet of a decoction of 60 gm. simaruba bark and 30 gm. cinnamon bark in 2,500 gm. water. Reduce to 2,000 or 1,750 gm. and add three tablespoonfuls of brandy. Four glasses are taken during the twenty-four hours for several days, adding a little laudanum if the stools are bloody. If there is nausea and vomiting, the second day the decoction is suspended and a dose of castor oil given instead. During convalescence castor oil is needed if thirty-six hours pass without stool. The food should be restricted to soft-boiled eggs, chicken broth, toast and boiled poultry. The after-condition requires treatment; healed ulcers reopen and require to be dressed. This local treatment is realized by bismuth internally to afford a protecting coating for the ulcerated walls, supplemented by systematic injections. He prefers for the latter a mixture of 10 gm. of bismuth subnitrate ground in a mortar, to which are added 1 gm. of gum tragacanth and 10 gm. of bismuth salicylate. When well ground together he adds 75 gm. of water and sets aside. He then adds later 425 gm. of water and filters through muslin. This injection is to be retained and repeated every second or third day, with boric acid enemata in the interim.

14. **Further Data in Regard to the N-Rays of Physiologic Origin.**—Charpentier announces that the emission of the *n*-rays by the living organism, mentioned on page 275 of the last issue, has nothing to do with heat, as they are emitted likewise by cold-blooded creatures. Contraction of a tendon does not increase the production of the rays along the course of the tendon, but only at its points of attachment. He ascribes this fact to the abundance of nerve terminals at these points. He has also found that compression of a nerve enhances its luminous properties. The functional activity of a nerve center is revealed by intensification of the luminosity over it. For instance, when the arms are moved the cervical enlargement of the spinal cord becomes more luminous. The center of Broca can also be located in the same way by having the subject speak in a low or loud voice. The results are less distinct with other centers. [These new rays were discovered in the laboratory at Nancy, France, where Blondlot is professor of physics. He called them the *n*-rays from the initial letter of the name of the city. Among their remarkable properties is that they pass through saline water, through lead .2 mm. thick, platinum .4 mm. thick, through tinfoil, a book of paper containing twenty-one sheets of gold leaf, mica, glass, paraffin wax and even sulphur, but they are arrested by pure water. Cigarette paper moistened with pure water will arrest the rays, while they will pass without hindrance through 4 cm. of normal saline solution. The rays are emitted by certain bodies, such as wood, glass and rubber, when forcibly compressed or twisted. Tempered steel, crystallized sulphur and hammered metals are permanent and spontaneous stores of the *n*-rays. Non-tempered steel is inactive. These and other properties of the rays are discussed in the *British Medical Journal* of January 9. Charpentier announces in still later research than the above that the heart, diaphragm and other muscles emit rays different from those emitted by the nerves, which are partly arrested by aluminum, while those from the former are not modified by it. Another difference is that the rays emitted by the nerves have a much stronger action on the phosphorescence of sulphur previously heated to 40 or 45 C. They are, therefore, not the true *n*-rays of Blondlot.—Ed.]

15. **Action of Radium on Different Tissues.**—Danysz relates experiences which show that the effect of the radium rays is more intense in young than in adult animals. He applies this fact to explain the selective action of the rays on neoplasms, while they traverse skin and muscle without appreciable action on them.

16. **Minimum Light Perception.**—Durand suggests the use of a gas flame as a test for the minimum of light perception and also its duration. The flame can be turned down gradually until the subject no longer perceives it.

17. **Unusual Localizations of Acute Circumscribed Edema.**—Since Quincke described this condition in 1882 he has had occasion to observe a number of unusual cases. In 4 the circumscribed edema affected the deep connective tissue. In the first 3 there was swelling of the periosteum concomitant with transient edema of the skin. The ulna, radius, small bones of the hand and the brow were thus involved, the periosteum somewhat tender. In 2 of the cases the swellings subsided in one day, but in another they lasted several weeks. Radiograms of the limbs showed no abnormal shadow, confirming the assumption of edema. One of these patients was a child. The affection probably originated in intestinal autointoxication. The attacks in one alcoholic and one neurasthenic subject recurred occasionally and with no appreciable cause. The fourth patient was a young woman with well-compensated aortic insufficiency, who exhibited painful swellings of the periosteum of radius, humerus, ribs and frontal

bone, each lasting several days, but disappearing much more rapidly than would have been possible with true periostitis. The symptoms were evidently due to an acute angioneurotic edema of the periosteum and connective tissue. The headaches likewise noted may have been due to an angioneurotic hydrocephalus. In 3 other cases the larynx was the seat of the acute edema. One was a youth of 17 who had two attacks, neither very serious. The second patient was a workingman of 26 who had suffered from eleven attacks of idiopathic edema of the larynx, otherwise healthy. The absence of coughing and pain and the acute onset spoke against tuberculosis or syphilis, and the non-febrile course and absence of other symptoms, against erysipelas. In a third case the lower air passages were likewise involved, the patient a young woman, a cook. The onset of the edema was acute and threatening, and the dyspnea and signs of pulmonary edema were so intense that she was carried to a hospital within thirty minutes of the first symptoms. By evening the lung findings were normal, but the development next day of edema of the upper lip, spreading until the eye was closed, cleared up the diagnosis. She stated on questioning that she had had such attacks during the last six years, but never so severe as the present one. Wright, Müller and Jamieson have reported similar cases, and Schlesinger believes that a certain number of cases of bronchial asthma belong in this category. In a further series Quincke describes a circumscribed edema affecting the tongue or soft palate and extending apparently into the digestive tract. These 3 patients were men, 18 to 56 years old. The transient character of the gastric disturbances and their association with circumscribed edema of the skin implied the probability that they were of the same character. The edema of the uvula in the third case was not accompanied by pain or fever, and the neighboring tonsils and pharyngeal mucosa were apparently intact. The symptoms on the part of the stomach and intestines suggested a gastro-intestinal catarrh, with the difference that they developed spasmodically and were not accompanied by any pain or tenderness in the entire digestive tract. The vomit after the food had been evacuated was a large amount of strongly alkaline fluid containing quantities of albumin and a very little blood and bile. These findings suggested the possibility that the edema observed in the uvula had extended down into the digestive tract and induced the secretion of the peculiar fluid noted. The bleeding was minimal and probably only the result of the violent retching. The urine the first day was highly concentrated and contained large amounts of indoxyl, probably from absorption by the altered intestinal mucosa. No cause for the attack could be discovered. The patient was a physician, 56 years old, who had been well up to the moment of the attack, leading his usual, regular life, with appetite for his food. Three days previously he had eaten some oysters and mushrooms. He had never before had any symptoms after eating them, and none of the other persons at the banquet had apparently suffered. An incubation period of sixty hours seems rather long, but has been noticed in other ptomain poisonings. It is possible that the absorption of the poison from the mucous lining of the digestive tract may have acted on the vasomotor, especially the trophic nerves, and caused the attack, similarly to "strawberry" urticaria. No attack of the kind nor of acute cutaneous edema had ever occurred in the patient's experience nor in that of any other member of the family. It is evident that intermittent hydrops of the joints and angioneurotic hydrocephalus belong in the category of this acute circumscribed edema. The basal type is comparatively simple and easily recognized, although there may be transitional forms with urticaria and erythema multiforme. We can assume that the same process as occurs on the skin may develop on the mucosæ, periosteum and connective tissue, possibly also in the muscles. This circumscribed angioneurotic exudation may likewise be responsible for acute, transient, "rheumatic" pains in the muscles, and for many neuralgias, for migraine and for certain of the manifestations of hysteria, as also for some of the disturbances of central origin in the motor and psychic field.

18. **Stenosis of the Cardia as Cause of Dilatation of Esophagus and Cure for It.**—Mikulicz reviews in detail the physiologic data on which he bases his assumption that dilatation of the esophagus is due primarily to contraction of the cardia. He describes a simple contrivance with which he is able to determine the pressure in the esophagus and obtain insight into its functions and the behavior of the cardia. To prevent and cure dilatation of the esophagus and its train of evils he advocates forcible dilatation of the cardia, similar to Récamier's method of forcible dilatation of the anus in case of painful fissure. He had an instrument made for the purpose, to be operated through the mouth and esophagus, but could never bring himself to operate in the dark as he had at first proposed, fearing that he might lacerate the cardia, with fatal peritonitis or mediastinitis in consequence. He therefore preferred to operate by way of the stomach, and now announces that he has performed this operation in 4 cases and apparently with perfect success. His first patient was a workingwoman of 30, who had been under treatment for six years, and the condition was growing constantly more deplorable even after gastrostomy. The fistula was enlarged, the stomach opened to admit the hand freely and, under control of two fingers, a long, curved forceps, the blades covered with rubber, was worked into the tightly closed cardia for 4 cm. The forceps was then gradually opened until the maximal distance between the backs of the blades reached 6 cm. The cardia was then stretched to its utmost, but without trace of tearing either in the muscle or mucosa. Two fingers could readily be passed into the esophagus beyond the hiatus esophageus. The wounds in the stomach and abdominal walls were then sutured, and after fluid food for two weeks the patient was able to eat any kind of food, and has been free from all disturbances, and has gained remarkably in weight since the operation was performed, Feb. 7, 1903. The second patient was a Berlin merchant, 39 years of age, and since the operation, last July, he has gained over 50 pounds. The 2 other patients were operated on in last October and November. The functional result in each case has been perfect to date. The cause of the retention in the esophagus was removed at one stroke, and in the 2 earliest cases radioscopy shows that the dilatation of the esophagus is gradually retrogressing.

19. **Production of Specific Substances from Bacteria.**—Mayer has continued his research in this line, and states that it has been crowned with success in the case of both typhoid and cholera bacilli. The addition of a weak alkaline ammonium sulphate to both kinds of bacteria causes an autolysis which results in the passage into the filtrate of specific substances from the bacteria. The same result can be obtained with cholera bacilli by shaking them for six to forty-eight hours at room temperature. The serum of rabbits inoculated with the filtrates thus derived acquires remarkable bactericidal power.

21. **Origin of Musical Heart Sounds.**—Galli illustrates a case which establishes that it is possible for an aberrant muscle fiber to induce a musical sound when the wall of the heart is indurated and the course of the blood stream induces vibration in the fiber.

24. **Importance of Intestinal Bacteria in Normal Conditions.**—Strasburger ascribes great importance to the action of bacteria in breaking up the cellulose cover of certain of the articles of food. He also calls attention to the fact that in normal conditions putrefaction does not occur in the small intestine, but is restricted to the large. The same bacteria are found in each, but recent researches suggest that the carbohydrates are able to protect the albuminoids against putrefaction. The lack of putrefaction in the small intestine he, therefore, attributes to the combination of intestinal bacteria and of carbohydrates. As the latter do not reach the large intestine in the same proportions, the bacteria alone are unable to prevent the development of the microbes which induce putrefaction. The chemical and mechanical stimuli from the presence of the intestinal bacteria promote peristalsis. Cases of habitual obstipation usually show a subnormal amount of these bacteria, especially of the colon and lactic acid bacilli, which he regards as the most important of the normal intestinal flora. As long as the walls of the intestines are sound the bacteria do not penetrate them, but the products of their metabolism are liable to be absorbed and may be responsible for certain general disturbances, such as headache, fatigue and depression, and also for certain skin affections. Metchnikoff's recent remarks in regard to the superfluous length of the large intestine, and his suggestion that it might be dispensed with, are answered by Strasburger to the effect that he would rather live a few less years than live longer with a constant, chronic diarrhea, which would be the necessary consequence of the removal of the large intestine. He summarizes his arguments in the statement that it is not the task of the practitioner to free the intestines of bacteria. Our efforts should aim to maintain the normal bacterial flora in normal conditions and normal proportions.

27. **Alterations in Testicles of Animals Exposed to Roentgen Rays.**—All the male rabbits and guinea-pigs exposed to the Röntgen rays proved sterile thereafter, as was mentioned in the report of Albers-Schönberg's experiences recently mentioned. Frieben adds now that none of the other organs of the animals showed any naked-eye changes, but the testicles were invariably found shrunken to one-third or one-half their former size, but otherwise apparently normal. The microscope revealed, however, that the epithelium of the tubuli seminiferi had almost entirely vanished and not a trace of spermatogenesis could be detected. There was no evidence of inflammation, and the intertubular connective tissue was apparently normal. The most labile cells of the organ had manifestly been affected by a degenerative process under the action of the Röntgen rays.

34. **Modern Theories of Eclampsia.**—Wormser describes tests of syncytiolytic serum, made according to the various theories and technics of Veit, Ascoli and Weichardt, as well as Liepmann's and his own. The results were inconclusive and unexpected in several ways.

35. **Perineum Tears.**—Bucura states that it is the rule at Chrobak's clinic to suture the tear at once. The experiences of 1901 were 279 healing by primary intention out of 313 sutured at once (in 3,333 births). Of this number 5 were slightly febrile and 3 febrile cases. In 16 others the wound healed partly by primary intention, and in only 18 was the healing secondary. Of the total 313, 93.6 per cent., healed without temperature; 2.6 were slightly febrile and only 3.8 had temperature, and these included a number with pneumonia, ulcers or endometritis.

36. **Fatigue Toxins and Antitoxins.**—Weichardt has found that the expressed juice from muscles of over-fatigued animals, injected into other animals, causes toxic symptoms after a latent period of twenty to forty hours. This fatigue toxin is destroyed by a temperature of 56 C. The juice is not toxic at first, but gradually acquires toxicity during the first forty-eight hours, and then gradually loses it again until all has vanished by the end of the week. He thinks that the toxic quality develops in consequence of a fermentative digestive process in the aseptic muscle juice. This assumption was confirmed by the fact that the onset of toxicity could be hastened by keeping the juice at 37 C. Intraperitoneal injection of the toxic fatigue-muscle plasm conferred on the serum of the rabbits thus treated a marked antitoxic power. The antitoxic serum thus produced was able to neutralize the fatigue toxin *in vitro* and in the animal body in a most conclusive manner. It is very resistant. He is now engaged on research to isolate the various elements of the toxin, separating the fatally toxic from the merely fatiguing elements.

37. **Staphylococci in Chronic Eczema.**—Veiel finds constantly and exclusively in the early stages of chronic eczema a staphylococcus identical with the essential pus cocci. It is found almost exclusively in the later stages. He thinks that the absence of other germs in the early stages excludes a specific germ for eczema.

38. **Operations on the Heart.**—Rotter has collected 46 cases in which suture of the heart was attempted. The recoveries number 19, or 41 per cent. He remarks that the flap-door incision, with the base on the median line, can be made equally well on the right side. He gives several suggestions for the perfection of the technic, and adds that exposure of the heart by this method is simple, and may be found useful for resuscitation in case of sudden death.

39. **Sun, Air and Mountain Climate in Treatment of Open Wounds.**—Bernhardt commenced to practice in the Engadine in 1886, and was at once impressed with the way in which wounds healed there. This, in addition to the beneficial effect of the mountain climate on tuberculosis, suggested that the conditions most favorable for operative treatment and healing of surgical tuberculosis and open wounds in general seemed to be combined there. Fresh meat hung up in the open air and sunshine dries, while retaining its flavor, and the aspect of meat thus dried suggested to him a similar method of treating open wounds. His first case was a patient who had been stabbed at seven points in the abdomen. The spleen had to be removed and the laparotomy wound burst open the eighth day and could not be sutured again. The edges were approximated with plaster, and the wound exposed for hours to the almost continual natural sunshine. The wound healed rapidly, and the results were so unexpectedly favorable that during the two years since, this method has been applied in nearly every case of open wounds and of closed lesions not far from the surface, especially tuberculous joint affections. The sunlight is particularly powerful among the mountains, as the chemical rays are not absorbed by impurities or moisture in the air, and the secretions of the wounds rapidly dry up under the influence of the dryness of the air. The wound becomes covered with a parchment-like skin, which protects it as well as any dressing under the clothing. Deep pockets heal rapidly under this exposure to the sun and air, usually on a veranda or in a room with open window. He gives a number of cuts of various wounds thus treated, including a dynamite injury of the hand, exposing the bone at several points, which healed completely in five weeks; one of an ulcus cruris and one of a large septic "pocket wound," which healed to an almost linear scar in six weeks; also one of scrofuloderma. In a case of extensive burn on the leg, 39 by 20 cm., which had proved rebellious to Thiersch grafting, after three months of sunlight treatment the knee-joint can be flexed to 90 degrees and ex-

tension is normal. The burn was of the second and third degree. In a case of septic bursitis of the olecranon with extensive skin defect, healing was complete in three weeks, with no trace of contracture.

40. **Radio-active Factor in Mountain Climate.**—Saake refers to the emanation of radio-active substance from the air, which Elster and Geitel first described in the *Physikal. Ztft.*, in 1902. He has found that it averages three to five times as much in the mountains as at the level of the sea. The difference in tension between the positive air and the negative earth—the potential—also increases with the altitude. His experiments indicate that these electric and radio-active factors have some share in the benefits of the mountain climate and that they might possibly be artificially increased.

43. **Handcuffs for Narcosis.**—The hands are drawn near together above the head, and are held in this position by a strap on each wrist, connected by a third long strap, which hooks into a screw ring on the edge of the table below, just under the patient's head. The hands and arms rest comfortably on a cushion, and while they have considerable play, yet they are unable to obscure the field of operation or the face.

44. **Treatment of Hemorrhagic Nephritis and of Early Stages of Nephritis in General.**—Baccelli has been treating these conditions for twenty years by endeavors to relieve the venous congestion in the kidney, which he considers mainly responsible for them. Stagnation of the venous blood entails degeneration of the epithelium and loosens it from its foundation. If the blood pressure in the ascending vena cava can be reduced or rendered negative, then the stagnating blood in the kidney is sucked into the vein and the kidney is given a chance to recuperate. This effect is most readily realized by tapping some remote branch of the vein. He withdraws as much as 300 gm. of blood from the vena pedidia. The results are surprisingly favorable. In a very severe case described the centrifugated sediment of the urine could scarcely be distinguished from pure blood under the microscope, but after the venesection the albumin disappeared at once from the urine, the blood soon followed, and in a few days the child was entirely restored. The result is neither so prompt nor so energetic when the blood is drawn from the arm.

45. **Digestive Tract in Pernicious Anemia.**—Four cases carefully examined and those reported by others indicate, according to the opinion accepted by Faber and Bloch, that the diffuse gastritis frequently observed in pernicious anemia and the anemia itself are subordinate to some primary cause. The digestive tract otherwise appeared normal. The absorbing and secreting functions seemed to be unimpaired. The most plausible theory for the origin of pernicious anemia is the assumption that it is the effect of some poison generated in the organism, and that this poison affects most perniciously the blood and the stomach. The lack of pathologic changes in the digestive tract below the stomach is no evidence against the assumption that this poison is generated in the intestines. In the one case of bothriocephalus anemia on record in which the intestines were examined less than an hour after death, the absence of pathologic changes in the intestinal walls was likewise marked, and yet there could be no question that the poison was generated by the parasite in the intestines in this case.

46. **Red Light Treatment of Smallpox.**—Finsen's reply to Schamberg's article in The Journal of May 2, 1903, was published in full in a later issue, page 1207, of the last volume. He gives the same here in Danish, and adds a list of five communications that have appeared during 1903 on the red-light treatment of smallpox, and all report favorable results. Besides this, he has had reports of two small epidemics on the Faroe Islands and in England, in which the red-light treatment produced an unmistakably beneficial effect. Naunyn was especially favorably impressed with its action in 11 cases at Strasburg, although one exceptionally severe confluent case terminated fatally. Emmerson, in a private letter to Finsen, expresses himself much more favorably than in his published report of his experience in the *Medical Times and Hospital Gazette* of July 4, 1903. Five of his 11 patients had never been vaccinated. Carassa did not have any suppuration fever in his 6 cases thus treated, including 3 confluent ones.

49. **Iodized Catgut.**—This communication was read at the Madrid Congress and has aided in the wider adoption of Claudius' method of preparing catgut with iodin. He has never observed any symptoms of intoxication from its use, while the catgut thus prepared is proving ideal in many respects. The technic was given in The Journal of Feb. 7, 1903, page 412.

50. **Emphysema.**—On the ground of 2 clinical cases and 15 experiments on the cadaver, Heerfordt describes the mechanism and symptoms of this condition. The article is illustrated.

55. **Trichinosis.**—Six cases are described and the various diagnostic points reviewed. Schroll thinks that the mild and isolated cases are frequently unrecognized. The affection may simulate typhoid at first with its fever, diarrhea and general ill feeling. In some of the cases the fever, ill feeling and pains in the limbs were attributed to influenza for several days until the attention was attracted to the edema. One mild case was assumed to be merely manifestations of the uric acid diathesis, and while the patient was being treated on this assumption the other members of the family began to exhibit the same symptoms, and the edema of the eyelids then attracted attention. An intoxication or infection was then assumed, with a suspicion as to trichinosis. A confrère called in consultation derided the latter diagnosis, and remarked that he had a number of cases with precisely the same symptoms in his charge at the time. The presence of a small, mild epidemic of trichinosis was later established. The edema, tenderness of the muscles and their infiltration testified against influenza. A gastro-intestinal catarrh with diarrhea, abdominal pains, edema of the eyelids and pains in the limbs may simulate the clinical picture of mild trichinosis, as he portrays by a typical case described. The pains are not localized in certain muscles, however, and there is no sensitiveness to pressure, infiltration nor stiffness in the muscles. The affection subsides in a comparatively short time, and the other members of the family do not present the same clinical picture.

56. **Formation of Uric Acid in the Human Body.**—Trautner presents arguments in favor of the assumption that gout in its primary manifestation is a colitis mucosa, and that the colon bacilli generate in the feces some reducing substance which becomes transformed into uric acid in its passage through the blood. Consequently, he proposes the theory that the colon bacillus is the primary cause of gout, and works up a good argument to sustain it, first establishing that the amount of uric acid in the urine increases with obstipation, that considerable diuresis and high specific gravity indicate an increased proportion, that ingestion of large amounts of albuminoids seems to increase the percentage of uric acid in

the urine, and concludes with the assertion that the purin theory is scarcely tenable.

**65. Organ Treatment of Tetanus.**—Virsaladze's communication is based on personal experience with 7 cases and the results obtained by others, as published in European literature, *especially in Slavonic publications.* Three died out of his 7 patients treated with injections of an emulsion of brain substance, and in one of the other cases the tetanus was of a very mild form. But the favorable outcome in the others and in those related in the literature indicate that this treatment has a promising future. He makes the emulsion as needed, using 15 to 20 c.c. of rabbit brain in physiologic salt solution, and injecting it subcutaneously. Four injections were made in four to nine days, and subjective improvement was marked, even after the first, in one typical case. The injections were accompanied by the usual measures. The 3 severe cases terminating in recovery were in patients 39, 52 and 23 years old. The fatal cases were in patients of 19, 16 and 46.

**66. Influence of Appetizers on the Digestion—Especially the So-Called Bitters.**—Borisoff gives curves and tables showing the influence on the secretion of gastric juice exerted by *giving his* est dog a little bitter substance *immediately* before his sham meal of meat. The dog has an opening into the esophagus and another into the stomach, according to Pawlow's technic for study of the digestive processes. The meat which he eats drops out through the hole in the esophagus, while the gastric juice flows out of the gastric fistula. Borisoff's previous research established the importance of the reflex action from the nerves of taste for the proper functioning of the secretory apparatus along the digestive canal. This view is corroborated by further tests of "bitters" as appetizers. He found that the secretions were increased by giving the dog a wad of cotton, soaked in tincture of gentian, immediately before giving him the meat. If the bitter was given as long as twenty minutes before, no effect was apparent. Others have established that large amounts of bitters have an inhibiting action on the gastric secretions. This latest research shows that a small amount, acting directly on the nerves of taste, immediately before the ingestion of food, has an unmistakable, stimulating effect on the secretory functions. The average amount of gastric juice secreted in 6 tests *without the* bitter was 101 c.c., while corresponding tests resulted in an average of 131.1 c.c. in 6 tests with the gentian. The amount obtained in the course of the two hours after the sham feeding ranged from 59.3 c.c. to 126.5 c.c. in the first series, and from 85.1 c.c. to 185.2 c.c. in the second series. He concludes from his research that the stimulant action of appetizers acting on the nerves of taste is now established beyond question, but that this stimulant action is very transient and is nullified if large amounts are used. The preferable method is in the form of "appetite drops," taking ten to twenty drops in a wineglass of water before each meal.

**67. Ankylosis of the Spine.**—Pussep draws sharp lines of distinction between the Bechterew and the Strümpell-Marie type. In a large table he gives the details of 28 cases of the former, as recorded by various writers, including 7 by Bechterew and 12 by other Russian writers, noting the condition of the reflexes, sensibility, muscle atrophy, etc. The article was presented at the Madrid congress.

**69. Lumbago.**—Gowers defines lumbago as an inflammation of the fibrous tissue of the muscles which by extension may involve the tendons, *and even the nerves,* the sciatic, for example. He calls special attention to a disorder similar in nature, but *differing in locality, which he calls muscular fibrositis* of the arm or brachial myalgia, characterized by pain in the muscles, not spontaneous, or only in a slight degree, but produced by contraction and tension, however slight. There may be tenderness to pressure also and the disorder may spread, as does the lumbosacral form, involving not only the nerve sheaths but the joint capsules. The brachial form is often mistaken and regarded as a neuritis when there is no nerve involvement. The familiar stiff neck is a milder form of this, and the muscles of the pharynx are sometimes involved. This muscular rheumatism is *more common in* the second half of life, and is often associated with gout. The brachial form he has seen especially in those who have an inherited tendency to gout, though not meriting its development by their habits of life. He also refers to traumatic fibrositis. As regards treatment *he insists on rest, special training* of the affected muscle, the use of aperients and rheumatic remedies, though they are much less effective in this condition than in rheumatism. The developed brachial form is often exceedingly obstinate. The *traumatic form of tendinous fibrositis when it* settled down to a stationary condition with pain on tension or even pressure resists *all treatment,* though it passes away in time like the other type, though the period may be long. Counter-irritation sometimes lessens the pain. Hypodermic injections of cocain seem to have a good effect.

70. *Chronic Cyanotic Polycythemia.*—Osler here describes a disorder which was noticed in THE JOURNAL, vol. xli, 44, p. 634.

**71. Diabetes Mellitus.**—Williamson calls attention to the slight excess of neuroglia tissue in Goll's columns, with a few scattered degenerated fibers in Burdach's columns and some degenerated fibers in the posterior nerve roots and posterior *horn. The spinal changes are probably* secondary to the altered blood condition in diabetes.

**72. Tendon Reflexes in Uremia.**—The exaggeration of tendon reflexes, especially knee-jerks and ankle clonus, in uremic conditions is noted by Stevens. He suggests that the exaggerated reflex is a symptom that may be of considerable diagnostic im*port in some cases.*

82. **Abdominal Surgical Disease.**—Bishop thinks cholecystitis may be caused by other organisms than the *Bacillus coli* and *B. typhosus*. In speaking of morbid changes in the large intestine he says that, in cases of painful defecation, attention should be directed to the anus and rectum. It is not safe to attribute the trouble to symptoms like hemorrhoids, etc., found there, but a complete rectal exploration is necessary. He mentions Houston's valves and the operations that have been suggested for the removal of the hypertrophy, growths in the sigmoid flexure and the treatment of mucocolitis. He speaks favorably of the operation of appendicostomy of Weir which has proven satisfactory in the one case in which he has used it.

83. **Physiologic Albuminuria.**—The conclusions of West's paper are summed up in the following:

> 1. Albuminuria may occur as a transitory symptom in persons who, except for this symptom, may be judged to be perfectly healthy, for they appear to be at the time and remain so. 2. But it may also occur in persons who though they appear at the time to be healthy develop signs of disease subsequently. 3. It is difficult to distinguish at a given time between those who will remain well and those who will not. 4. It is difficult to exclude for certain many of the pathologic causes to which the albumin might be due. In other words, though there may be no proof that these causes are present, there is equally no proof that they are absent, and in some cases the result shows that they were not absent. 5. Speaking generally, the larger the amount of albumin in the urine and the longer it persists the greater the probability of some permanent disease. 6. Continued observation of these cases shows that the so-called physiologic albuminuria does very appreciably increase the risk of life and that this risk grows rapidly with every year of age after 30 years. As the result of the foregoing proposition we are led to the general conclusion that functional albuminuria is never, strictly speaking, physiologic at all, but that it is, on the contrary, always pathologic though not necessarily renal.

105 "Paratyphoid" Fever. R. Tanner Hewlett.

93. **Typhoid Fever.**—Sandwith describes the conditions of typhoid fever in Egypt. The natives appear to be practically immune, especially in the rural districts, though during military service they are to a certain extent susceptible to it, but much less so than European soldiers. Europeans in Egypt have to use the same precautions against typhoid as elsewhere.

94. **Typhoid in India.**—Enteric fever appears to be common in India. Before the introduction of the Widal test it was largely overlooked among the natives as the symptoms appear to be somewhat different than those in European cases. He has only seen one classical enteric temperature chart in all his experiences there and that was in a native of the mountain regions. The classical temperature course is also rare in European cases.

95. **Typhoid in China.**—Cantlie says that typhoid fever is common among Europeans in certain cities in China and scarcely met with in others, and among the Chinese is rare anywhere. Of course, the statistics as to the Chinese are not complete, as they prefer their own physicians, though they go freely to the missionaries for surgical disorders. The method of preparing their food protects them. They eat very little uncooked food and drink but little but what has been boiled. The use of milk is rare. In Shanghai typhoid is very frequent, somewhat less so in Hong Kong. In the interior cities like Chunking, Chinkiang, Soochow, Ningpo and other places, it is hardly known even among Europeans. While the use of human fecal matter for manure is general in China, yet it undergoes fermentation and bacterial treatment in cemented tanks before it is used and it is possible that even the raw vegetables may not be dangerous as regards spreading the disease. The type of the disease in Hong Kong is rather unpronounced. Chinese children are subject to the infection, as has been shown by their experience in orphan homes under European management.

96. **Typhoid in Camps.**—Tooth discusses the subject of the cause of typhoid fever among soldiers and mentions, besides drinking impure water, the possibility of its conveyance by bathing, soil infection, sand storms, flies and the crowded condition of the tents.

97. **Typhoid Infection in London.**—Newman points out that while the case rate of typhoid in London remains fairly constant year by year, water-borne infection can not be considered the chief cause. Personal contact and shellfish, he thinks, are the main channels of infection. A further study in this line is required.

99. **Rigors in Typhoid Fever.**—Bolton discusses this somewhat unusual symptom, reporting a case and giving the temperature charts. Violent rigors usually indicate the presence of some toxic substance in the circulation. The case reported seems to support the theory that some intestinal irritation is in many of these cases responsible, though there is no doubt that the rigors may be excited by peripheral irritation. It does not appear that they materially affect the prognosis, though they produce trying effects on the patient. Their treatment must be on general principles, bearing in mind that they are not of such serious import as their appearance might lead one to think.

100. **Anti-Typhoid Inoculation.**—Wright's article appears here only in the first part describing the methods and the history of inoculation. He remarks on the cumulative effects of two or more inoculations. When the second one falls on a positive phase of the former inoculation, or on any period when the blood contains an increased quantity of antitropic substances, there is developed a cumulative high tide of immunity. When, on the contrary, the inoculation falls on a negative phase of the first, there is a cumulative susceptibility produced. In the second part of his paper he proposes to discuss the application of these principles to preventive inoculation.

103. **Typhoid Perforation.**—Mackenzie insists on the importance of early diagnosis and calls attention to certain confirmatory signs. Abdominal pain should be the most important danger signal. Vomiting, nausea, hiccough, repeated action of the bowels at short intervals, rigors, swelling, mental excitement or symptoms of perforation may accompany the pain. The doctor should be immediately summoned and should look for confirmatory signs; notice any change in the temperature, a sudden drop or rise, though steady temperature does not exclude perforation. There may be a change in the pulse, the beats becoming more frequent and weaker, though increased rapidity does not always follow. There may be a change in the facies, a pinched or drawn look, depression of the corners of the mouth, sinking of the eyes, blueness of the lips and swelling, but still more important is the abdominal pain, usually most marked over the lower half of the abdomen. Rigidity is exceedingly important. The presence of softness or flaccidity is always reassuring. Obliteration of liver dulness is a valuable sign if present, though not always free from ambiguity. If there is no tenderness, if the abdominal wall is flaccid, the liver dulness and the flanks normal, one may rest assured that there is no perforation. He thinks operation will be much more successful in the future than it has been in the past.

104. **Treatment of Typhoid.**—McCrae gives the treatment as followed in the Johns Hopkins Hospital. The diet consists chiefly of milk and albumin water. Sometimes ice cream, tea

and coffee and clear soups are allowed. Beef tea and the peptonoids are never given. If a change of diet is required, reduction or exclusion of milk is practiced, and only whey or albumin given. More patients are over- than under-fed. The necessity of giving large amounts of water is insisted on. Hydrotherapy by the Brand method is followed and the constant rubbing while in the bath is insisted on. The general management consists in giving the patients rest, while diet and baths are employed. A useful mouth wash is 1 to 20 solution of carbolic acid with listerine and glycerin, āā ℥i, and boric acid solution (saturated) ad ℥xviii, used after each nourishment. A condition of constipation is preferred and is the rule. If necessary the bowels are moved every second day by a simple enema. Alcohol is not given as a routine, most patients going on to recovery without a drop. It is given freely if there is any sign of toxemia or failing circulation. Many patients get *no medicine at all; none of the so-called intestinal antiseptics* is employed. Strychnin is administered for heart weakening *and sometimes digitalin, small doses of bromids and codeia* for headaches. In severe toxemia salol infusions are used if the patient can not take enough fluid by the mouth. Convalescence may be most troublesome. There is safety in not returning to solid food too soon. Soft food is taken after a few days of normal temperature and soft toast is added at the end of a week. From the seventh to the tenth day scraped beef or sweetbread is given. After this the diet is increased. The patient is usually propped up in bed about the tenth day and *allowed up in a wheel chair about three or four days later For anemia iron is given. The complications of hemorrhage,* cholecystitis, perforation, etc., are noticed. McCrae protests against giving opium in hemorrhage cases as it interferes with the diagnosis. In case of cholecystitis, operation not too much delayed is advisable, though it is often difficult to decide. In perforation early operation is insisted on. Disinfection of the urine is important; urotropin in 10 to 15 gr. doses ought to be given by the mouth until the urine is clear. Tender toes is a troublesome condition, and painting them with equal parts of iodin and *alcohol nearly always gives relief.* To sum up, a simple diet with *abundance of water, systematic baths, drugs given only when special indications arise*, are the important *points.* Special *attention* should be given to the recognition of early abdominal complications and prompt operative treatment when required.

Investigations with the Respiration Calorimeter, in Co-operation with the *Pennsylvania* State College Agricultural Experiment Station. By Henry Prentiss Armsby, Ph.D., and J. August Fries, B.S. Paper. Pp. 77. Washington: Government Printing Office. 1903.

The Treatment of Fractures: With Notes on a Few Common Dislocations. By Chas. L. Scudder, M.D., Surgeon to the Massachusetts General Hospital. Fourth Edition, Thoroughly Revised. With Nearly 700 Original Illustrations. Cloth. Pp. 534. Price, $5.00. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The Distribution of Blood Vessels in the Labyrinth of the Ear of *Sus Scrofa Domesticus*. By George E. Shambaugh, Instructor in the Anatomy of Ear, Nose and Throat. Printed from Vol. X. The Decennial Publications. Paper. Price, $1.25. Chicago: University of Chicago Press. 1903.

Social Diseases and Marriage. Social Prophylaxis. By Prince A. Morrow, A.M., M.D., Emeritus Professor of Genito-urinary Diseases in the University and Bellevue Hospital Medical College, New York. Cloth. Pp. 390. Price $3.00 net. New York and Philadelphia: *Lea Brothers & Co. 1904.*

The Prevention of Consumption. By Alfred Hillier, M.D., C.M., B.A., Secretary of the National Association for the Prevention of Consumption *(London). Revised by Professor* R. Koch. With Illustrations. *Cloth. Pp. 226. Price, $1.50 net.* New York and Bombay: Longmans, Green & Co. 1903.

The Self-Cure of *Consumption* Without Medicine, with a Chapter on the Prevention of Consumption and Other Diseases. By Charles H. Stanley Davis, M.D., Ph.D., Member of the Connecticut State Medical Society. Cloth. Pp. 176. Price, 75 cents. New York: E. B. Treat & Co. 1904.

Third Annual Report of the New York State Hospital for the Care of Crippled and Deformed Children, for the Year Ending September 30, 1903. Hospital Located at Tarrytown, N. Y. 1903. Paper. Pp. 28. *Albany: J. B. Lyon Company. 1904.*

The Blues (Splanchnic Neurasthenia), Causes and Cure. By Albert Abrams, A.M., M.D., (Heidelberg), F.A.M.S., Consulting Physician, Denver National Hospital for Consumptives. Illustrated. Pp. 240. Price, $1.50. New York: E. B. Treat & Co. 1904.

Chart of Acute Poisoning, Giving Descriptive Classification and Varieties, with Special Symptoms, Chemical and Physiologic Antidotes, Fatal Dose, Simple Tests and Remarks on Treatment. For Gratuitous Distribution. New York: Victor Koechl & Co.

*Prostatic Hypertrophy, from Every Surgical* Standpoint. By George M. Phillips, M.D., and Forty Distinguished Authorities. Edited and Compiled by S. C. Martin, Jr., M.D. Cloth. *Pp. 176.* Price, $1.75. St. Louis: Lewis S. Matthews & Co.

Lessons on Massage. By Margaret D. Palmer, Masseuse and Manager of the Massage Department of the London Hospital. Second *Edition.* Cloth. *Pp. 261. Price, $2.50.* New York: William Wood & Co. 1904.

The World 1904. Almanac and Encyclopedia and *Officially* Compiled Guide to the Louisiana Purchase Exposition. Paper. Pp. 541. Price, 25 cents. By mail, 35 cents. New York: Press Publishing Co.

Gynecological Nursing. By Netta Stewart, Sister in the Extramural Gynecological Wards of the Royal Infirmary, Edinburgh. *Cloth. Pp. 174. Price, $1.00.* New York: William Wood & Co. 1903.

Are We to Have a United Medical Profession? By Charles S. Mack, M.D., La Porte, *Ind.* 1904. Pasteboard. Pp. 44. Price, $0.25, *postpaid.* La Porte, Ind.: Herald Print.

The Nutrition of the Infant. By Ralph Vincent, M.D., Member of the Royal College of Physicians. Cloth. Pp. 295. Price, $3.50. New York: William Wood & Co. 1904.

Report of the Library Committee of the Faculty of Medicine, McGill University, Montreal, Canada, 1902-1903. Paper. Pp. 17. Montreal: Modern Printing Company.

Nineteenth Report of the State Board of Health of Wisconsin. *September 30, 1902.* Cloth. Pp. 304. Madison: Democrat Printing Company. 1903.

### New Patents.

Patents of interest to physicians, January 5 and 12:

749014. Invalid sling. Perry W. Atkinson, Troy Center, Wis.
748581. Ear. Charles E. Carll, Indianapolis.
749128. Sterilizer. Arthur Castle, Rochester, N. Y.
748934. Machine for operating on corns. John E. Doldt, Portland, Me.
748708. Insoluble gelatinous product and producing same. Henry V. Dunham, New York.
748709 Casein cellulose composition and producing same. Henry V. Dunham, New York.
748732. Optometrist's trial-frame. Charles L. Hogue, San Francisco.
748752. *Shield for clinical thermometers.* Eugene O. Koeneman, Eldora, Iowa.
748636. *Receptacle for disinfectants.* Wm. L. McDonald, Chicago.
749078. Manufacturing ether. Otto Meyer, Richmond, Va.
748650. Pessary. Frank L. Priest, Dallas, Texas.
749547. Pasteurizing. Michael L. Fesenmeier, Cumberland, Md.
749180. Surgical *pan.* Wm. A. Galloway, Xenia, Ohio.
749555. Truss. Jacob Harris, St. Louis.
749689. Surgical instrument. Thomas A. Houghton, Rochester, N. Y.
749690. Massage instrument. Nicolay *Jacobsen,* Christiania, Norway.
749213. Electromagnetic device for vibratory massage. Eugen K. Muller, Zurich, Switzerland.
749220. Medicated tampon. Edmund M. Pond, Rutland, *Vt.*
749453. Attaching device for sanitary *napkins.* Charles H. Schopbach, Aurora, Ill.

### THE INFLUENCE OF TRAUMA IN THE PRODUCTION OF MOVABLE KIDNEY.*

M. L. HARRIS, M.D.
*CHICAGO.*

The influence of trauma in the production of movable kidney is a subject of special importance to the railway surgeon who is so frequently called on to decide whether or not a movable kidney in a given case is the result of a certain injury or accident. It is a common belief of the profession, as well as of the laity, that a movable kidney is frequently the result of an injury. Most writers on the subject assign to trauma an important place among the etiologic factors, but few of them indeed offer any evidence, such as the report in detail of cases, or of reasoning based on pathologic conditions found, in support of their statements. It is evident, therefore, that the statement has been passed on from one author to another without the subject receiving the careful attention which it deserves.

Before entering in detail into this phase of the question, it will be necessary to consider the etiology in general of movable kidney. It was early observed that the large majority of cases occurred in women, and as movable kidneys were first discovered in women with lax abdominal walls, the result of repeated childbirth, it was at once concluded that repeated pregnancies were the cause of the movable kidneys. More extensive observations, however, gradually disclosed the fact that movable kidneys are much more common than at first supposed; that they frequently occur in the unmarried and in those who have never borne children, and, furthermore, that the right kidney is affected much more frequently than the left. Notwithstanding these facts, repeated pregnancies is still given as the most important cause of movable kidney by almost all authors. Of 126 women examined in order, it was found that those in whom the kidneys were not palpable or abnormally movable—55 in number—the average number of children born per woman was slightly greater than in those in whom movable kidneys were found—some 71 in number. Of 107 cases of movable kidney in women, from the author's records, 40 were single and 65 married, 2 not stated. Of the 65 married women 12 had never borne children; in other words, of 105 women with movable kidneys 52 had never been pregnant and 53 had borne one or more children.

These facts show conclusively that pregnancy in itself is not a material factor in the production of movable kidney. That retrodisplacements and prolapse of the uterus and vagina with lacerations of the perineum are material factors in the production of movable kidney, as stated by some, is likewise disproved by the above facts.

Another commonly stated cause of movable kidney is rapid absorption of the perirenal fat, but there are no facts in support of this statement. On the contrary, clinical experience, as well as observations at the operating table and in the dead-house, are opposed to it. Such a cause should be equally operative in both sexes, but we know how rare the affection is in man as compared to women. The condition is not observed to follow acute wasting diseases, nor is it more common in emaciated subjects. While in some cases the amount of perirenal fat found at operation is small, in others it is abundant, and in the dead-house a small amount of perirenal fat is frequently found without a movable kidney. Movable kidneys are so frequently found in young women who have never been pregnant; whose pelvic organs are normal; whose abdominal walls are firm and, therefore, no diminution of intra-abdominal tension present; who are not emaciated and who have never received any material injury; that all who have given the matter any serious thought and study have been compelled to seek other causes for the condition. The more the subject is studied the more it becomes evident that those in whom movable kidneys are found are defective in bodily form, that they deviate in some particular from the highest normal type.

Thus the investigations of Wolkow and Delitzin show deviations in the anatomic configuration of the posterior abdominal wall. The paravertebral niches in which the kidneys lie and which in the normal well-built individual are deep and show a distinct pear- or funnel-shape, are shallow and of cylindrical shape in those with movable kidneys, thus favoring displacement of these organs. Albarran[1] ranks movable kidneys with the bodily stigmata of degeneracy, and Stiller finds them associated with dilatation of the stomach and a loose tenth rib, which he likewise considers a sign of degeneracy. Becker and Lenhoff[2] found that the least abdominal circumference was much smaller in proportion to the body length in those with movable kidneys than in normal individuals, and the author in a paper[3] read before the American Surgical Association in 1901 demonstrated by a series of careful measurements of the body form that there was a distinct relative contraction or diminution in the capacity of the middle zone of the body in all individuals with movable kidneys. For the method and details of measurement I refer to my article above mentioned. Of 107 cases of movable kidney that I meas-

[3] THE JOURNAL A. M. A., June 1, 1901.

The class of cases, however, which most frequently comes before the railroad surgeon is of another kind. Of course, many cases of severe and serious injuries are encountered in railroad surgery, but those in which movable kidney is alleged to have resulted are usually not of the severer kind. The most frequent accidents are falls while alighting from or attempting to board cars; jars and general concussion from collisions, or by reason of the cars jumping the track, etc. In the majority of cases the movable kidney has not been discovered for some weeks or months after the accident, when the case has been worked up by the personal injury lawyer and doctor. The influence of these latter factors on the patient is often very great, and might furnish the basis for a very interesting study.

But laying all such questions aside for the present, let us consider what influence, if any, trauma may have had in the production of movable kidney in these cases. I have analyzed 1,300 cases of railroad injuries that have come under my supervision during the past two years. Of this number 728 were males and 572 females. Although several of the males presented symptoms indicating injury to the kidney, there were no cases of movable kidney observed. Among the 572 females there were 41 cases of movable kidney in which the question of a traumatic origin arose. The ages of these patients ranged from 16 to 62 years; 28 were married and 13 single. Both kidneys were movable in 9 cases, the right alone in 32. In no case was the left kidney alone found movable. In 20 cases measurements of the body form were made, and all without exception possessed the characteristic body form with contraction of the middle zone.

It should be remembered in considering the details of these cases that they were all suits for damages. The manner in which the injury was received was based on the patient's own statements, and at times was not borne out by the evidence. It is well known, too, that the patient's statements as to symptoms, previous state of health, etc., must be received and weighed with great care and judgment, for they often have not the same significance and value as the statement of a patient seeking relief of a physician under ordinary circumstances.

Of the 41 cases 9 were seen and examined within thirty days after the accident.

Case 1.—Miss B., aged 21, single. While she was standing up in a car, about to get off, the car bumped into a car ahead and she was thrown against an upright post, striking the right side of the abdomen. She got on another car and rode several miles down town; she had a hysterical fit and was taken home. I examined her the next day. She was a slender woman, of nervous temperament. Pulse 82. Temperature 98.2. No bruises were to be seen anywhere on the body. The right kidney was movable to one inch below the umbilicus. It was not tender nor painful on motion.

Case 2.—Mrs. D., aged 31, married, was riding in a buggy which was struck by a passing car. She was thrown forward and got her foot caught in the spokes of the wheel, spraining her ankle. She was pregnant four months, but did not miscarry. She was examined six days after the accident. There were no objective evidences of injury except that to the ankle. Right kidney was movable to the second degree.

Case 3.—Mrs. J. W., aged 22, married, in a collision was thrown forward and backward, then fell on the floor. She continued on her journey, remained away visiting all day and night, and returned home next day. She was not laid up at all, but claimed injury to her back, a sprain of the lumbar region, and bruises of her back, right elbow and both legs. Examination 13 days after the accident showed no bruises about back or elbow. There were two small bruised spots on the legs. The right kidney was movable to the second degree, and not tender. There were no symptoms referable to the kidney. The contracted middle zone was shown by measurement.

Case 4.—Mrs. F. A., aged 22, married. The car in which she was riding collided with a wagon, and she was thrown back in her seat. She was frightened because she saw someone fall off the car. She was seven weeks pregnant and miscarried five days later. Examination 18 days after accident showed that she had recovered nicely from the miscarriage. The right kidney was movable to the second degree, but there was no tenderness or soreness about it. No bruises were found anywhere about the body.

Case 5.—Mrs. S. S., aged 21, married, was thrown to the floor of a car by a collision. She fractured the right forearm and bruised her right side. Her physician stated that he found a small amount of blood in her urine soon after the accident, but when examined 17 days after the accident the urine was normal. The right kidney was movable to the second degree. It was somewhat tender, but was not enlarged, nor was there any enlargement or thickening about it.

Case 6.—Mrs. N. D., aged 32, married, in a collision was thrown forward, then backward. She struck first on the front of the chest and epigastric region, then on the elbow, arm and back. The injury complained of was to her elbow, arm and shoulder, with tenderness in the epigastric region. Examination 23 days after accident showed the right kidney movable to the second degree, bruises of the arm at the shoulder and the elbow. There were no symptoms of injury to the kidney.

Case 7.—Miss S., aged 27, was sitting in a car, the side of which was struck by another car; this jarred her back. She was menstruating at the time. Her physician said he discovered a movable kidney very soon after the accident, and that she had blood in the urine, which in all probability was simply the menstrual blood. Examination 27 days after the accident showed the right kidney movable to the second degree. Measurement showed typical body form.

Case 8.—Mrs. S., aged 26, married, was getting on a car just as it started. She did not fall but swung around. She claimed a wrench of her side and her hips, although she did not feel anything at the time. She was not laid up, and had no physician. She complained of backache and pain in her side. Examination 27 days after accident showed a nervous, anemic woman, with characteristic body form and both kidneys movable to the second degree. The uterus was retroverted and the patient had leucorrhea.

Case 9.—Mrs. K., aged 61, married, asserts that while walking on the street she was struck by a car, knocked down and rolled under the fender. She was able to get up alone, went home in a car and was in bed ten days. She asserted that her whole right side was bruised from her neck down. Her physician said he found blood in the urine; that the right kidney was pushed out of its capsule; that she had two attacks of uremia from kinking of the ureter; and that he was obliged to massage the kidney back into place. When examined 27 days after the accident she was up and visiting friends. No bruises of any kind were to be found. The right kidney was found movable, but the urine was clear.

These 9 cases were examined so soon after the accident, and the kidneys were found so very movable and so free from unusual tenderness that it is very evident that in none of the cases was the accident the cause of the mobility. The injuries received were not severe in any of them, Case 5, with a broken forearm, being the worst perhaps in this respect. Case 9, which at first glance seems to show a causal relation between the injury and the movable kidney, must be rejected. The statements of the patient and her physician were not believed, for reasons which need not be mentioned. The case was afterward settled for a very nominal amount.

There were 6 cases which were examined within three months after the accident.

Case 10.—Mrs. M., aged 57, married, fell on her right side while getting off a car. She claimed womb trouble with frequent urination as a result. Examined two months after the accident, there was found a laceration of the perineum with prolapse of the uterus and vagina. She had had eight children. There was a very pendulous abdomen with general visceral ptosis and a movable right kidney. It was very evident that none of these conditions resulted from the fall, and the case is therefore rejected as showing causal relations.

Case 11.—Mrs. G., aged 25, married, fell on her left side and abdomen while getting off a car. She was two months pregnant and miscarried. She had had two children. Examination, a little over two months after the accident, showed a laceration of the perineum, a tender uterus, prolapsed ovaries, and the patient pale, weak and nervous. The right kidney was very movable to the third degree and somewhat tender. As she had been in bed most of the time since the fall on account of the miscarriage, and as there had been no symptoms referable to the kidney, it was very evident that such a high degree of mobility could not have been produced by the fall.

Case 12.—Mrs. T., aged 36, married, was thrown from a car while turning a corner and struck on her left side, shoulder and hip. She was examined less than two months after accident. Five years ago she had been ill with peritonitis for six weeks, and had had pain and soreness in abdomen since. She was very nervous and hysterical. There was a small bruise over the sacrum. The right kidney was very movable. There were no symptoms referable to the kidney. The movable kidney was undoubtedly of long duration.

Case 13.—Mrs. W., aged 31, married, did not fall, but in getting on a car she was swung around against the side of the car. Her injury was not severe in any sense. Examination two and a half months after accident showed a very characteristic body form and both kidneys movable to the second degree. There was a marked pulsation of the abdominal aorta. No possible connection could be found between the injury and the movable kidneys.

Case 14.—Mrs. M., aged 40, a widow, owing to sudden stopping of a car was thrown forward, then backward, striking her right side against the seat. She was in bed four weeks. There were no symptoms of injury to the kidney. She complained of loss of hearing, headache and pain in the right side. Examination three months after the accident showed diminished hearing in both ears from chronic middle-ear trouble and the right kidney movable to the third degree. The high degree of mobility and the marked contraction of the middle zone show clearly that the kidney had undoubtedly been movable many years.

Case 15.—Mrs. P., aged 29, married, fell to the floor as the car in which she was traveling started, injuring her right knee and her left side. She complained of the knee and of excessive flowing. Examination three months after the accident showed an injury to the right knee, a prolapsed left ovary and chronic endometritis. The right kidney was movable to the second degree. The nature of the injury and the lack of symptoms excludes the accident as the cause of the movable kidney.

There were 5 cases examined from four to six months after the accident. Of these cases, 16, 17 and 18 gave distinct histories of movable kidney existing before the accident, and can therefore be excluded. They are:

Case 16.—Mrs. B., aged 34, married, was thrown out of a carriage and the carriage wheel passed over her right hip. She had chronic heart disease, lacerations of the cervix and the perineum, and double movable kidneys, right to the third degree, left to the first degree, all dating before the accident.

Case 17.—Mrs. H., aged 40, a widow, fell while getting off a car, striking her left hip. The right kidney was found movable to the second degree. Characteristic body form present. She had felt a lump (kidney) in the right side from before the accident.

Case 18.—Miss N., aged 26, fell in a sitting position in getting on a car. Her injury did not incapacitate her. Double movable kidneys, the right to the second degree, and the left to the first degree. The symptoms dated back long before the accident. Characteristic body form found.

Case 19.—Mrs. B., aged 30, married, was alighting from a car when it started. She held on to the hand rail, then fell on her back. She was in bed six weeks and asserted that her uterus had been displaced, but the physician had corrected same. She was a thin, emaciated subject with pulmonary tuberculosis. The uterus was in good position. Right kidney movable first degree; there were no symptoms.

Case 20.—Mrs. H., aged 50, married, was thrown off a seat by the car starting and struck her left knee, side and shoulder. Both kidneys were distinctly movable and the left one tender. The nature of the injury was such that it could not possibly have produced double movable kidneys, although it may have added to the tenderness of the left one.

The remaining 21 cases were examined from six months to three years after the accident.

Case 21.—Miss R., aged 22, was standing when the car started, causing her to fall against the stove, then against the knees of sitting passengers. She bruised her right knee, hip and shins. After riding several miles home, she was in bed one month. She was examined 6 months after the accident. She asserted that she had a great number of nervous symptoms. She was tall and slender and had the characteristic body form and a very movable right kidney. A retroverted uterus was found, also inflammation and thickening of right tube and ovary with considerable leucorrhea from infection. The injury was not severe, but the patient was a hysterical neurasthenic.

Case 22.—Mrs. S., aged 28, fell from a car by reason of a collision with a wagon. She bruised her right hip and had hemorrhage from the womb and was in bed ten days. She was a nervous patient, with a long history of irregular menstruation, frequent urination, backache, etc. She showed the characteristic body form and had a tender right kidney, movable to the third degree. An enlarged, tender, prolapsed right ovary and a laceration of the cervix were also found. She had two children, aged 6 and 3½ years.

Case 23.—Miss K., aged 24, struck left knee against seat in getting on a car, but did not fall. She developed marked symptoms of hysteria. There was no possible connection between the injury and a very movable right kidney.

Case 24.—Miss S., aged 20, was thrown against the door frame in attempting to get out of the car. Her real injury was slight, and she was more frightened than hurt. She gave a history of repeated attacks of Dietl's crises with vomiting for some years before the accident. They were called "bilious attacks." These attacks continued after the accident and were supposed to be due to an appendicitis produced by the accident. Six months after the accident the appendix was removed but without benefit, as attacks still continued. The sensitive movable right kidney had not been discovered. She had a typical body form.

Case 25.—Mrs. H., aged 36, was thrown from a car while rounding a curve and injured her right knee, which laid her up three months. She said her right kidney was dislocated by a fall from a car six months previously. Examination showed the uterus retroverted, a laceration of the cervix, the right kidney movable to the first degree. No relation existed between the injury and the movable kidney.

Case 26.—Mrs. S., aged 35, in getting off a car was swung around, striking her left side against an upright. She did not fall and did not think she was hurt. Examination showed a lateral curvature of the spine, the characteristic contracted middle zone and the right kidney movable to the third degree; left one movable to the first degree. She complained of numerous symptoms characteristic of neurasthenia. The movable kidney was undoubtedly of long standing.

Case 27.—Mrs. P., aged 32, was shaken up somewhat by the car jumping the track. She said that she did not think at first that she was injured. The next day pains developed in the abdomen and back. Examination showed a heavily loaded colon from constipation. The right kidney was freely movable. There was the typical body form. The real injury here was too slight to have had any effect on the kidney.

Case 28.—Mrs. —, aged 55, fell in getting off a car and struck on her hip and back. She was in bed two months with pain in hip, back and shoulder. The right kidney was movable to the first degree with a positive index; the mobility was evidently of long standing.

Case 29.—Miss R., aged 26, fell from a car alighting on her feet, then on left side. She was in bed nine weeks with pain in the spine and the hip. She was a frail, slender woman, very constipated, had marked dysmenorrhea and general nervous symptoms. Her right kidney was movable to the second degree.

Case 30.—Miss A., aged 29, was thrown down while getting on a car and fractured her left humerus at about the center. She has lateral curvature of the spine with slightly deformed chest. Both kidneys were movable, the left worse than the right. There were no symptoms of injury to the kidneys.

Case 31.— Mrs. D., aged 27, when a car jumped the track, was thrown to the floor, then struck back against car seat. Patient was in bed two and a half months with pain in back, back of head and neck, and left side of the abdomen. She had dysmenorrhea, never had been pregnant. The right kidney was found movable to the second degree. There were no symptoms referable to the kidney.

Case 32.—Miss R., aged 16, was knocked down by a car and rolled under the fender. She was able to get up and walk to the station after the accident. Her physician said that the uterus was displaced by the accident and he replaced it. At examination the uterus was found in normal position. The right kidney was movable to the second degree and the characteristic body form was present. There were no symptoms of injury to the kidney.

Case 33.—Miss H., aged 21, was thrown from a bicycle and fractured her left arm near the elbow, bruised her back and leg and was rendered unconscious. She was in bed three weeks. Examination showed a lateral curvature of the spine and a right kidney movable to the first degree, positive index. There were no symptoms referable to the kidney at any time.

Case 34.—Mrs. R., aged 37, was thrown forward while alighting from a car and cut her left leg. She asserted that exophthalmic goiter resulted from the accident. She has had one child since. Examination showed an old adenomatous goiter, which she had had for some years. There were no symptoms of the goiter. The right kidney was movable to the second degree. There were no symptoms of injury to the kidney. Typical body form was found.

Case 35.—Miss W., aged 30, fell down and was struck by a car in the region of the anus. She asserted she was laid up eight months with rectal trouble and during that time was operated on for hemorrhoids. Two months after the operation she had a perirectal abscess. Examination showed a right movable kidney and characteristic body form. The case is very suspicious.

Case 36.—Mrs. M., aged 41, was thrown to the ground, striking on her right side. She was in bed two weeks on account of a bruise to her right knee. elbow and side of body over the lower ribs. She had had ten children. Her abdomen was loose and pendulous. The right kidney was movable to the second degree; left kidney first degree. She had frequently noticed a swelling or a tumor in her right side, which disappeared again; evidently the right movable kidney and certainly of long standing.

Case 37.—Miss A., aged 22, received a fright in a collision and claims she was stepped on. Her real injury was slight, but she developed hysterical spells. The right kidney was movable to the first degree.

Case 38.—Mrs. H., aged 26, in a collision, was thrown from her seat and said that passengers stepped on her. She was able to get up and walk home without difficulty. She miscarried at the third month and was in bed six weeks complaining of nervous symptoms. Double movable kidneys were found, but there were no symptoms of injury to them.

Case 39.—Miss G., aged 20, jumped from a car and fell. She had a very movable right kidney with Dietl's crises—certainly antedating the injury.

Case 40.—Mrs. R., aged 38, was struck by a car and knocked down. She miscarried at the second month. She had had seven children and one miscarriage. She showed on examination very marked visceral ptosis with a movable right kidney, third degree, which was undoubtedly of long standing.

Case 41.—Mrs. S., aged 37, was struck by a car and knocked down, bruising her right arm. She had six children. Examination showed a very hysterical patient with retroversion of the uterus, a laceration of the perineum and a movable right kidney.

After carefully analyzing these 41 cases, taking into account the injuries and the manner in which they were produced, the symptoms, the examination of the patients, etc., one is forced to the conclusion that not in a single case is it at all certain, nor even probable, that the kidney was made movable by the accident. It should not be concluded, however, that a kidney already movable may not be injured by violence, as well as one that is normally fixed, or that symptoms connected with a movable kidney may not be aggravated by injury, but the most probable explanation of many of these cases is that the injury but made manifest or called attention to a movable kidney which had existed for some time without giving rise to symptoms or without being recognized. It is a well-known fact that many women have movable kidneys for years without experiencing any special symptoms connected thereto, and that symptoms may appear after a slight injury, as a fall, or after a spell of sickness or unusual fatigue, or even after a nervous shock. I recently had a case illustrating this:

A young married lady of 26 years was hastening to catch a train. She tripped lightly and fell, but did not hurt herself *in the least*. She caught her train and while making the *journey a collision occurred*. She received no physical injury whatever, but was considerably frightened. She was about two months pregnant at the time. A few hours later she had an attack of pain in the right side of the abdomen. During the next year and a half she had several similar attacks at irregular intervals of a few weeks. Examination disclosed a movable *right kidney*, to which her attacks were undoubtedly due; but it would be *ridiculous to say that the collision or fright* was in any way responsible for the movable kidney.

From a careful study of the subject, I present the following conclusions:

1. Movable kidneys occur in women with a particular body form, and practically all women with this body form have movable kidneys of greater or less degree.

2. Movable kidney is not produced immediately, but requires time for its development.

3. While it is possible to injure, crush or suddenly displace by violence a normally fixed kidney, such displacement is always accompanied by laceration of the perirenal tissues, which is manifested by distinct local and general symptoms.

4. Severe injuries involving the kidney or perirenal tissues are seldom or never followed by movable kidneys. Sterns says he has not been able to find a single case in the literature where such a result occurred.

5. A movable kidney is never the immediate result of a single trauma.

---

**Additions to Medical Knowledge.**—I have always thought (and not without reason) that to have published for the benefit of afflicted mortals any certain method of subduing even the slightest disease was a matter of greater felicity than the riches of a Tantalus or a Cresus. I have called it a matter of greater felicity; I now call it a matter of greater goodness and of greater wisdom.—*Sydenham.*

# THE NERVOUS PHENOMENA ASSOCIATED WITH MOVABLE KIDNEY.[*]

WHARTON SINKLER, M.D.
PHILADELPHIA.

It is only within a comparatively recent period that the attention of the profession has been directed to the frequent occurrence of movable or floating kidney, and it is within a still more recent time that the importance of the symptoms arising from this condition has been appreciated. The frequency of movable kidney is a point on which there has been wide diversity of opinion. All authorities agree that movable kidney is much more common in women than in men, and it is also agreed that it most frequently occurs between the ages of 25 and 40 years, and is rarely found in girls before puberty. It is also most common in women who have been pregnant. Some writers state that this condition of the kidneys is found in 25 per cent. of women who are examined for pelvic, dyspeptic or other troubles, while others regard the condition as comparatively rare. Franks[1] insists on a distinction between floating kidney and movable kidney. The former, he says, is very rare and is a pathologic curiosity, while the latter is common. Floating kidney is a congenital condition and the organ is freely movable in the cavity of the abdomen, it is surrounded by peritoneum and is possessed of a mesonephron. Movable kidney is an acquired condition and the organ is mobile behind the peritoneum.

When looked for in the cadaver, the kidney is not often found displaced, and this is probably due to postmortem conditions, the kidney having a tendency to settle into its normal position, and the fatty capsule surrounding the organ becomes solidified and helps to hold it there. Epstein states that movable kidney was found only five times in 3,658 postmortems, and Landau in an examination of hospital records from 1870 to 1879 found reports of only 4 cases out of 6,999. On the other hand, Lindner[2] asserts that in his experience, one out of every five women has a movable kidney, and Mathieu out of 306 women examined in hospitals, found movable kidney in 85, or 25 per cent.

There is no doubt that a kidney which is displaced to only a slight extent is overlooked, and in the detection of a movable kidney, much depends on the manner in which the examination is made. It is the experience of every one to have found at one examination that the kidney was so much out of place that its whole outline could be readily traced, while on the next occasion it may have been impossible to feel the organ at all. Lindner gives the following as his method of examination for displaced kidney: He stands at the right side of the recumbent patient, places his right hand against the anterior abdominal wall and then presses the left against the back of the lumbar region so as to push the kidney forward. The patient is then placed on her right side with the knees drawn up; by sharply shaking the body, the kidney, if movable, will fall forward. He says that frequent examinations are sometimes necessary to detect the abnormality.

Noble[3] declares that an examination of a patient lying down is a most unreliable way for determining the presence of movable kidney, and he believes that this condition is frequently overlooked if the examination is not made when the patient is standing. His method is as follows: "The patient's clothing should be loosened, all bands about the waist unfastened and the skirts supported by a nurse or assistant so that the patient will not be embarrassed with the fear that her clothing will fall off. She should then stand before a table or desk of convenient height, about thirty inches, with the examiner seated on her right. The patient then bends forward from the hips, and supports some of her weight by resting her hands on the table. She is directed to respire regularly, care being taken to relax herself thoroughly during the expiration. The examiner's left hand is placed against the lumbar region posteriorly and his right hand in a corresponding position in front of the kidney. By a conjoint manipulation, the region between the two hands can be carefully palpated and if present, the kidney is easily recognized." The points to be looked after are the shape and size of the kidney and the fact that it can be readily displaced upward beneath the margin of the ribs, and that it will return to its former location as soon as the examiner's hands no longer support it. When the kidney is compressed, as a general rule, the patient complains of tenderness or pain of a peculiar character, and often makes the statement that the pain causes her to feel faint and somewhat nauseated. In some cases the manipulation will be more successful in the knee-elbow position.

The causes of displaced kidney have been variously assigned to falls, pregnancies and tight lacing, but it is probable that these conditions are only indirectly causative, as there must be some predisposition to displacement in order to effect a marked change in the position of the organ. Probably the most common predisposing cause is the lack or loss of adipose tissue. It is undoubtedly true that movable kidney is usually seen in women who are thin or emaciated. Possibly one reason for its more frequent detection in thin women is that in them it is easy to palpate the whole abdomen, while in stout women the difficulties are great, but it is no doubt true that movable kidney does not occur so frequently in stout women as in thin.

The kidney has no proper ligaments, but is embedded in a thick cushion of fat which aids in keeping the kidney in place and there is also a large amount of connective tissue which binds it to the loin behind and to the abdominal viscera in front. Anything which causes absorption of the fat will necessarily allow greater mobility to the kidney. The right kidney is much more frequently displaced than the left, although occasionally it is found that both kidneys are displaced. Schutze found in 73 cases the right kidney displaced 65 times—the left 18 and in both 14 times. Noble says that he has never seen a case in which the left kidney was displaced independently of the right.

The symptoms of movable kidney are for the great part reflex in character, but there are also those which are local or due to mechanical action. The principal symptoms connected with displaced kidney are pain and dyspeptic and neurasthenic disorders. It is interesting to note that the symptoms are by no means in proportion to the degree of displacement of the organ. It frequently occurs that in cases where the displacement is only slight, the reflex symptoms are most marked. Noble has called attention to this and also to the fact that in this it is analogous to pelvic disorders. He thinks that the explanation is that in extreme displacement the nerves become overstretched and the circulation has had time to adjust itself to the changed condition.

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

[1] Twentieth Century *Practice of Medicine*, vol. ix, p. 781.

[2] Sajous' Annual, 1889, vol. 1. G., p. 21.

[3] Gaillard's Med. Jour., 1895, vol. lxi, pp. 59, 65.

The degree of pain varies from a dull aching to acute lancinating pain. It is usually referred directly to the region of the kidney and is more or less constant. In many cases it is uncomfortable or painful for the patient to lie on the side opposite the displaced organ. If there should be a twist or kink of any kind in the ureter, this will give rise to intense pain and eventually to hydronephrosis. Should complete rotation of the kidney occur, not only is the ureter compressed, but the renal vessels and nerves are also involved. The result is agonizing pain, with collapse, nausea, cold sweats and scanty urination. In short, most of the symptoms of renal colic are present.

Neuralgic pains in different parts of the body are complained of. Irritable bladder is common and so also is pain in this organ, which begins in the kidney and passes down the ureter into the bladder. Dysmenorrhea is frequently associated with movable kidney, and there are also symptoms referred to the ovaries and bladder of a dragging character or weight, which are really due to a displaced kidney. There are frequent disturbances of the liver and gall bladder as a result of mechanical dragging by the kidney and symptoms closely resembling those of gallstones are not unusual in connection with movable kidney. Dyspeptic symptoms are almost constantly met with in cases of displaced kidney. They may vary in degree and kind from slight indigestion and flatulence to intense nausea and pain. In connection with gastric disturbances are found palpitation of the heart and other disturbances in the action of this organ.

Intestinal disorders are also common. In some cases there is marked mucous colitis with its distressing local and general symptoms. What are popularly called bilious attacks frequently occur in patients with movable kidney. In these attacks there are headache and vomiting of large quantities of bile stained mucus. The gastric symptoms have been attributed by one writer to the direction of the displaced kidney and the pressure of this organ on the stomach, but this is hardly a satisfactory solution of the case. It is more likely that the gastrointestinal symptoms are reflex rather than mechanical.

A recent writer, Dr. Sherman Thompson Brown,[4] has reported two instructive cases of pancreatic diabetes, which he believes were due to misplaced right kidney. In both cases nephropexy was performed. Both patients made an uninterrupted recovery and from the time of the operation no sugar was present in the urine in either case. In the interesting article which this writer has presented, he goes fully into the anatomy of the pancreas, duodenum and kidney. He explains the intestinal and pancreatic disturbances in displaced kidney by the pulling upon the duodenum and the colon with the duodenum where it crosses the kidney, and the pressure of the misplaced organ. In his cases, he believes that the glycosuria was due to dragging on the pancreas by the kidney.

Edebohls[5] believes that movable or displaced right kidney is directly responsible for almost every case of appendicitis. He, as is well known, is a strong advocate for operations to anchor the kidney. It would seem, therefore, that movable right kidney is held responsible for nearly all the ills to which flesh is heir.

The most common symptoms associated with movable kidney are disorders of the nervous system, such as hysteria, neurasthenia and mental depression. It must be borne in mind, however, that at least 50 per cent. of the cases of movable kidney present no symptoms whatever, and that, therefore, we can not expect to find in every neurasthenic woman a displaced kidney. At the same time there is such marked causative relation between movable kidney and neurasthenia that it behooves us to examine every woman presenting neurasthenic or hysteria symptoms, for the position of the kidneys. It is not necessarily the case that there is severe pain complained of in connection with the nervous systems, for frequently it is found that a neurasthenic woman has not experienced any pain or discomfort in the region of the kidney, nor has she been aware of any malposition of the organ.

Probably the most constant nervous disorder in a patient with displaced kidney is neurasthenia. Such patients are thin and in addition to general neurasthenic symptoms, suffer from much gastric disorder. There are in some cases, attacks of severe epigastric pain with retching like the gastric crises of tabes and often there is gastric pain which comes with regularity one or two hours after eating and large quantities of gas are belched up simulating gastric ulcer. The usual remedies for indigestion and flatulence afford little or no relief. Some patients find that lying down and kneading the right side gives ease. Bloating from distention of the bowels with gas is a common symptom, and this is frequently accompanied with palpitation of the heart and pain in the precordia. These patients also have more or less pain in the region of the affected kidney, which is generally of a dull aching character, and is often attributed to intestinal disturbances. The patient sleeps badly and the sleep is broken and disturbed by dreams. Any form of exercise, even walking or driving, is liable to cause pain and aching in the right hypochondrium and considerable exhaustion. Patients with movable kidney are also extremely nervous and irritable, and are often in a condition which makes them not only uncomfortable to themselves, but a burden to their friends. In some cases, the various manifestations of hysteria may be presented. I recall one patient whose right kidney was so much displaced that it could be readily outlined in the region of the umbilicus, who had severe hysterical seizures in which she became unconscious and raved.

There are various reflex hysterical disturbances met with in movable kidney. Of course, there may be only an accidental association between these conditions, but from the fact that after an operation for fixation of the kidney these symptoms disappear, it is evident that there is more than a coincidence between the symptoms.

Hypochondriasis and mild mental disturbances like melancholia are sometimes associated with movable kidney, but these conditions occur only in cases of long standing.

These nervous phenomena rarely occur in men, but when they are met with in that sex they are very intense. The treatment of movable kidney is palliative or radical. In a certain proportion of cases, the application of abdominal belts with properly adjusted pads seems to afford relief, but in the majority of instances the use of any kind of apparatus is entirely unsatisfactory, as it is most difficult to get a belt which can be made to fit accurately. Many cases in which the amount of displacement is moderate in degree, are greatly benefited by the rest treatment, and even cases in which there is a considerable displacement of the organ are distinctly benefited by such a plan of treatment. Every case of displaced kidney should have the benefit of systematic and intelligently directed rest treatment before resorting to operation. All the procedures connected with the rest treatment tend to benefit cases with movable kidney. As long as a patient is on her back the kidney remains in a normal position. By improving the general nutrition of the body, the weight is increased, and this will add to the deposit of fat in all the tissues and restore that which has been lost by absorption from the envelope of the kidney, and thus secure it in its proper condition.

---

[4] Phila. Med. Jour., April 4, 1903, p. 594.

[5] Amer. Jour. of Obstet., 1895, vol. xxx, p. 161.

In addition to these mechanical influences from rest treatment, the isolation, regimen and moral influences which are brought to bear on the patient, relieve the nervous and neurasthenic symptoms which are present, in almost every instance.

In cases in which there is true floating kidney or much displacement of the organ, and in which the rest treatment has been faithfully tried without benefit, operation should be resorted to. There are also cases in which, for various reasons, it may be undesirable to adopt rest treatment, and in these, nephrorrhaphy may be resorted to at once. The operation has been performed in various ways by different operators. The five principal methods are as follows:

1 The sutures may be passed through the fatty capsule alone.

2. They may be passed through the fibrous capsule of the kidney.

3. They may be passed through the substance of the kidney itself.

4. The capsule may be split and dissected off and this stitched to the lumbar muscles.

5. The substitution of gauze packing for sutures to hold the kidney in place until the formation of permanent adhesion of the kidney in its new position, the wound being left open to heal by granulation.

The object in all of these is to fix the kidney in the loin. The operation has now been performed a great number of times with marked success as to retaining the organ in position. The mortality is exceedingly small. In 134 cases collected by Keen,[6] there were four deaths, giving a death rate of 2.98 per cent. The experience of most operators has been that the kidney remains in position after it has once been fixed by operation. Edebohls states that in 193 operations upon 186 patients, in none of the cases did he find the kidney misplaced on subsequent examination. Henry Morris states that in 98 operations for movable kidney, he has not reoperated on a single patient.

The ultimate results of nephrorrhaphy as regards the symptoms, depend to a considerable extent on the nature of the case. The pain, weight and dragging is almost invariably relieved by an operation. The immediate effect on disorders of the digestive system is not always satisfactory and it often is a considerable length of time after the operation before these symptoms are relieved. Flatulent dyspepsia and constipation often remain for a long time, and the same may be said of the nervous phenomena. Few cases are immediately relieved of neurasthenic and hysteric symptoms immediately after operation, and it is not reasonable to expect that such symptoms would disappear at once. As a rule, they have lasted for a long time, and the neurasthenic and hysteric condition has become established in the individual. We cannot, therefore, expect that these symptoms will be relieved without suitable treatment being pursued for a reasonable length of time. It is, in operations for movable kidney, just as it is in operations for ovarian disease in patients who have become neurasthenic. The cause of the trouble may have been removed, but the disease which has been induced does not disappear without proper treatment.

I will only relate two cases to illustrate what has been dwelt on in the foregoing remarks.

Case 1.—Mrs. A., aged 40, mother of four children, has for several years suffered from a number of symptoms of neurasthenia. She has had flatulent dyspepsia and suffered from constipation. She has been very nervous and has become unable to perform her duties at home. She has lost much flesh and is far below her normal weight. The right kidney was found to be markedly displaced, and could be readily outlined. There is apparently little local pain. She was treated systematically by the rest cure, and gained flesh and lost her neurasthenic symptoms. Fifteen years later she was seen, and stated that she remained in excellent health.

Case 2.—Mrs. B., aged 25, has for several years suffered from severe attacks of bilious vomiting associated with headaches and pain in the right hypochondrium. She has been neurasthenic, irritable and emotional. She has constant dragging pain in the right side of the abdomen, most marked just below the margin of the ribs. She had frequent attacks of mucous enteritis. The right kidney was found to be movable and readily outlined. The patient was thin but not anemic. A course of rest treatment was followed by improvement in her general symptoms, but after a few months she had almost as much pain and suffered from as frequent attacks of bilious vomiting as before. In September, 1902, she was operated on by Dr. John B. Deaver and the kidney was fixed in position. She made a satisfactory recovery from the operation and all of her symptoms have gradually disappeared. She has gained flesh and has comparatively little trouble with her digestion, and while not entirely free from pain, has so much less that it gives her but little inconvenience. She has gained markedly in weight.

## DISCUSSION.

**Dr. A. P. Ohlmacher**, Gallipolis, Ohio—Dr. Sinkler has referred to the difference between the figures of the pathologist and those of the clinician as to the frequency with which movable kidney is met. This discrepancy is, perhaps, partly due to the fact that it is not the routine custom to look for this anomaly in making an autopsy. The displacement is usually best made out with the body in the recumbent position, but if the autopsy is not made immediately after death, the fixation of the tissues tends to anchor the kidney, as well as the other intraperitoneal contents. If one will take the pains to grasp the kidney in its peritoneal covering, it will frequently be found that the range of movement varies greatly, and in this way one can sometimes detect a movable kidney. My attention has frequently been called to this in cases where the mesentery was unusually long and associated with a displaced stomach and colon, and on examining the kidney it would be found in its normal position, but it could be very readily drawn out and sometimes displaced for a considerable distance. I was rather surprised that Dr. Sinkler has laid no stress on the association of movable kidney with movability of other abdominal organs, that is, to a splanchnoptosis. This association is so common that I am sure it deserves some consideration. The digestive symptoms to which he referred are frequently the result of an associated gastroptosis, and are not referable to the kidney condition proper. In a like way the intestinal symptoms are often referable to displacement of the colon.

**Dr. R. C. Moore**, Omaha—The number of cases of movable kidney that we come across in general practice is astonishing, and it has become my custom when I am called to see a patient who has any symptoms pointing to the abdomen, to invariably look for floating kidney. The general symptoms, as Dr. Sinkler has described them, do not point to any disorder of the pelvic organs, but more especially to the gastro-intestinal tract. The author also referred to the connection of appendicitis with this trouble. This form of appendicitis comes under the head of colic of the appendix, and an operation on the movable kidney will not cure the trouble in the appendix. After the kidney is anchored, it becomes necessary to perform a second operation on the appendix. These cases of appendicitis are non-suppurative in character at the onset, but there is a constant danger that infection may take place. In examining for movable kidney, the upright position allows it to fall forward, but it is often very difficult to map it out on account of the rigidity of the abdominal walls. My custom is to have the patient sit on a chair and bend forward so that the abdominal muscles become relaxed. If the kidney is displaced, it can usually be made out by examining in this position.

---

[6] Trans. Amer. Surg. Assn., 1890.

Dr. J. L. Miller, Chicago—In quite a large percentage of cases of movable kidney of the second or third degree we also find gastroptosis. The latter condition does not always give rise to gastric symptoms. Many of these patients have shown marked improvement on the application of a suitable bandage; in others, an operation was necessary. Before we can say that these patients are cured, it is necessary to keep them under observation for a long time, as relapses are not uncommon. The neurasthenic symptoms will be apt to return even if the kidney has been restored to its proper position. The beneficial results of the treatment, as far as the nervous symptoms are concerned, are, I believe, largely due to suggestion.

Dr. A. R. Elliott, Chicago—I have been astonished at the frequency with which I have found gastroptosis and enteroptosis associated with movable kidney. These patients sometimes fall into the hands of the gynecologist, who may, perhaps, find and repair an old rupture of the perineum without relieving any of the patient's abdominal symptoms, which are the result of an abdominal ptosis. A satisfactory abdominal support and measures directed toward a proper regulation of the digestive functions with promotion of the general muscular tone, give the best results in these cases.

Dr. A. C. Croftan, Chicago—I think it is difficult to determine whether floating kidney is ever the cause of neurasthenic symptoms. I have never seen such a patient cured by the replacement of the kidney alone. There is usually in these cases general abdominal ptosis, and often associated with this condition is a loose floating twelfth rib. Whether the neurasthenia and the relaxation of all the abdominal supports are both effects of the same cause, or whether the latter determines the former, is often difficult to say. Theoretically, one might imagine that splanchnoptosis, with the resulting derangements of function, might cause certain vague general symptoms that can be conveniently included under the gaping category of neurasthenia; sympathetic irritation may also possibly be incriminated. The anchoring of a loose kidney or uterus, however, can hardly be expected to cure the patient. I certainly never hesitate to send my neurasthenics to the abdominal surgeon even if the kidneys were loose.

Dr. F. Savary Pearce, Philadelphia—I believe that in a great many cases of floating kidney, associated with general splanchnoptosis, the whole process is the result of depressed vitality in a neuropathic subject. The treatment should be directed first along neurologic lines—to repair the nervous system, and when the patient's general condition is improved, it is certainly advisable to put the organs back into their proper places. As to the gastro-intestinal symptoms being necessarily due to an associated gastroptosis or enteroptosis, I am not willing to subscribe to that theory, because I have seen two cases of undoubted floating kidney with marked gastro-intestinal symptoms in which there was no displacement of the stomach or bowels. The gastric symptoms, under such circumstances, are probably at least partially of reflex origin, or they may be the result of a nervous dyspepsia. The ideal treatment is to remedy the nervous condition. I have never found much benefit from the use of a belt.

The ethics of the American Medical Association do not interfere with any physician in the exercise of good business sense, and they are seldom criticised except by those who wish to dodge.—*Alkaloidal Clinic.*

# A CONSIDERATION OF THE NEUROSES OF STATUS LYMPHATICUS.*

A. P. OHLMACHER, M.D.
GALLIPOLIS, OHIO.

Status lymphaticus, otherwise known as the lymphatic constitution, lymphatic diathesis, lymphatism, etc., is a so-called constitutional disorder, characterized by a persistence or hyperplasia of the thymus, general lymphadenoid hyperplasia, frequently associated with cardiac and arterial hypoplasia, and evidences of rachitis. The principal morbid anatomic features of status lymphaticus are a persistent or hypertrophic thymus, general or regional lymphadenoid hyperplasia including the lymphoid elements of the spleen, hypoplasia of the arteries and heart, very often with the osseous changes of rachitis. Occasional or accessory features are a thick skin, edema of the skin, lungs or brain, hypertrophic thyroid, hypertrophy of the brain, hypoplasia of the sexual organs, and lymphocytosis. A pronounced general active hyperemia is usually discovered in lymphatic individuals dying suddenly.

That there is a close morbid anatomic association between status lymphaticus and rickets has been abundantly proven, particularly in the case of lymphatic infants. Still we are not at present in a position to say that all cases of status lymphaticus are associated anatomically with the rachitic dyscrasia, nor do all cases of rickets exhibit the evidences of lymphatism, though its coincidence with enlarged spleen and hyperplasia of the mesenteric nodes is well known. In infants dying in the lymphatic state a mild grade of craniotabes, the rosary, curvature of the long bones or spine, and enlarged epiphyses have been manifested as rachitic osseous changes; and in older children or adults several instances of rachitic spinal curvature, pigeon breast, narrow pelvis, and curvature of long bones have been found.

It will not be germane to our present purpose to enter into details concerning the morbid anatomy of the lymphatic state, and your attention is therefore invited to several peculiar clinical manifestations of status lymphaticus which I have ventured to class as its neuroses. The first of these is sudden death, which, because of its morbid anatomic association, shall be designated thymic or lymphatic sudden death. An abrupt lethal ending in victims of lymphatism is not an uncommon phenomenon, both in infants and young adults. It occurs under various circumstances, as by a sinking spell with or without convulsions in the presence of spectators, during sleep ("found dead in bed"), during a bath or while swimming, in surgical narcosis, or during the performance of some minor operation as the removal of the tonsils or adenoids, extraction of teeth, injection of curative sera, or following certain hydrotherapeutic measures. This phase of our subject is discussed in detail by such writers as Grawitz, Paltauf, Pott, Nordmann, Kundrat, Escherich, Gallatti, Ewing, Blake and others.

That lymphatic sudden death should be looked on as an abruptly fatal neurosis seems entirely permissible, and the term "Nervenschlag," used by the Germans to describe its mode of onset, is equally suggestive. Moreover, in cases that have come under accurate observation, convulsive phenomena have been described as ushering in the fatal event, and some of the accounts recall to one's mind the similarity between the abrupt assault of an attack of major epilepsy and the sudden spasm of lymphatic sudden death.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

Infantile eclampsia is, to my mind, another neurosis whose anatomic affinity with status lymphaticus will be more fully elaborated as our knolwedge increases. The association of teething fits and rickets is generally conceded, and in a few instances in which search was made with that particular end in view, status lymphaticus was disclosed at autopsy. Personally my experience is limited to two cases, in one of which a six months' infant died during general convulsions of the kind usually designated "teething fits," and in the fresh material from the autopsy sent to the laboratory the enlarged thymus and lymphadenoid hyperplasia of status lymphaticus were readily disclosed. In another case of a young infant dying in convulsions, the formalin-preserved specimens which came into my possession for study revealed the changes of the lymphatic state in a degree even more striking.

Closely united in clinical analogy with the eclampsia of infancy are spasm of the glottis (laryngismus stridulus, etc.), and infantile tetany (carpo-pedal spasm). These neuroses have repeatedly been associated with the rachitic dyscrasia and, more recently, it has been found that the anomalies of status lymphaticus could be disclosed on proper autopsic examination. Without reviewing the familiar clinical characteristics of these affections, therefore, it becomes of interest for us, in the present connection, to recall that each of the three neuroses—eclampsia, glottic spasm and infantile tetany—are in some way related to lymphatism, as has been pointed out, especially in the papers by Pott and Escherich.

In the course of my studies in the pathology of epilepsy pursued at the Ohio Hospital for Epileptics I have become impressed with the frequent coincidence of idiopathic epilepsy and status lymphaticus; and it seems to me justifiable to assert that idiopathic major epilepsy is a neurosis of the lymphatic state in the same relationship that lymphatic sudden death, infantile eclampsia, tetany, and spasm of the glottis are so considered. Epilepsy and teething fits have long been regarded as sustaining a clinical affinity, and the same has been asserted of epilepsy and tetany, glottic spasm, and (by my own endeavors) lymphatic sudden death. Moreover, on purely clinical grounds, epilepsy has been classed as a neurosis of rickets. In view of these considerations, therefore, it may be asserted with reasonable assurance that these neuroses exhibit both a clinical and morbid anatomic kinship and that their anatomic basis is the lymphatic or rachitic dyscrasia.

As to the morbid physiology of this interesting group of nervous diseases and the attempt to reconcile them with status lymphaticus as the morbid anatomic basis, data are still meager. The German writers have recognized the neuropathic element in these affections, whence the term "Nervenschlag" to describe the attacks. Sudden death is regarded as a reflex cardiac paralysis, the increased susceptibility of the heart to various forms of irritation being a part of the lowered vital resistance incidental to the constitutional disorder. Escherich considers a latent irritability of the central nervous system to be characteristic of the lymphatic constitution, causing reactions in the form of spasmodic conditions in various parts of the body in response to trifling stimuli. He would regard the constitutional disorder as the expression of an incomplete or perverted metabolism, that is, as a dyscrasia or chronic intoxication comparable with Basedow's disease or myxedema.

Gallatti directs attention to a peculiarity of status lymphaticus which, in my opinion, is a factor of importance in explaining some of the clinical phenomena, viz., the peculiar predisposition to edema. This, as Gallatti asserts, is shown by the pasty condition of the skin, by the tendency to eczema, and by the occurrence of edema of the brain. I would add, from my observation on lymphatic epileptics dying abruptly in a single seizure or from rapid status epilepticus, edema of the lungs as another one of the manifestations; an observation already made by Kundrat in a case of sudden death during chloroform anesthesia, by Langerhans in the case of his son's sudden death after a prophylactic antitoxin injection, and by Paltauf in at least one of his cases of sudden death. Gallatti holds that slight factors like autointoxications of various kinds may incite this tendency to edema into activity. Piedecocq, in his belief that sudden death in infants with hyperplastic thymus is due to increased intracranial pressure resulting in compression of the medulla, is evidently on the tack taken by Gallatti, though he wishes to ascribe the increased cerebral pressure to compression of the great vessels in the neck caused by a backward flexion of the head aggravating the pressure already exerted by an enlarged thymus.

Whatever its mechanism, I am, from my observation on lymphatic epileptics and my reflection on these studies, strongly disposed to the belief that a periodic increase of intracranial pressure acting either on the exterior or interior of the brain, or on both portions simultaneously, and manifesting itself as a result of the tendency to edema characteristic of status lymphaticus, is a directly provocative factor of such neuroses as spasm of the glottis, tetany, infantile eclampsia, epilepsy, and the various forms of sudden death incidental to the lymphatic state. According to this view the clinical phenomena would depend on the extent and location of the intracranial edema, or, in other words, on the portion of the encephalon particularly subjected to pressure. In event of compression of the external portion of the cerebrum various convulsive disorders of the motor apparatus are provoked; when the balance of pressure becomes so distributed as to raise the intracerebral pressure other severer symptoms occur, ending, in case of sufficient pressure on the floor of the fourth ventricle, in sudden respiratory or cardiac failure. Granting the hypothesis just advanced, we are brought one step nearer the explanation of the modus operandi of several obscure neuroses whose kinship has repeatedly been recognized on purely clinical grounds and whose morbid anatomic association is proved by the establishment of the lymphatic state as a common basis for all. Cheadle's dictum that "laryngismus, tetany, and general convulsions are the positive, comparative and superlative of the convulsive state of childhood," finds support and elaboration.

## DISCUSSION.

Dr. D. I. Wolfstein, *Cincinnati*—I am sorry that Dr. Ohlmacher did not mention what criteria at autopsy enabled him to diagnose the status lymphaticus.

Dr. A. P. Ohlmacher, Gallipolis, Ohio—The criteria referred to were disclosed with relative uniformity in suitable epileptic subjects at the Ohio Hospital for Epilepsy. It is necessary, in order to find the persistent thymus gland, the enlarged intestinal follicles and the enlarged spleen, that suitable autopsy cases should be selected. These lesions are found in young patients who are the victims of idiopathic epilepsy.

They are not ordinarily found in epileptics who are over thirty years old, or in those who have died of prolonged dementia or exhaustion or of certain acute infections, but only in those who die suddenly, and particularly in those whose nutrition is not materially impaired. The narrow arteries and relatively small heart are common as persistent features even after the patients have reached an advanced age.

**Dr. H. T. Pershing**, Denver—Can Dr. Ohlmacher give us any information as to the treatment?

**Dr. H. T. Patrick**, Chicago—I have been more or less familiar with Dr. Ohlmacher's investigations in epilepsy, and I think there is nothing so far to quite warrant the conclusion that the convulsions were caused by edema affecting the surface of the brain. I believe that this is a highly improbable solution of the epileptic paroxysm. Edema does not form instantly: it requires a certain length of time, while the paroxysm is almost instantaneous.

**Dr. D. I. Wolfstein**, Cincinnati—It seems to me very difficult to explain the occurrence of such phenomena as laryngismus stridulus or tetany or the manifestations of rickets on the theory of edema. Other objections to the theory are that this condition does not always occur in those individuals who show pronounced manifestations of rachitis, and that we see cases of prolonged lymphatic edema without the occurrence of convulsions or sudden death. We frequently see it in chronic alcoholics, and in such individuals there must be a certain amount of status lymphaticus and edema of the cortex.

**Dr. A. P. Ohlmacher**—Little has been accomplished in the way of treatment. The extract of the thymus gland has been used, but it has not given sufficiently good results to make it noteworthy. The treatment of the rickets is the prophylactic measure, and is, I believe, the essence of our present hope in the successful treatment of epilepsy. I am confident that Gowers is right in his belief that there is a distinct relationship between epilepsy and rickets, and that the prevention of rickets is one of the most important considerations in the prevention of epilepsy. The theory that the edema has a causative relation to the paroxysms of epilepsy or to laryngismus stridulus or to sudden death, is not original with me. The German authorities have already called attention to the fact, and its analogy to the lightning-like edema of the lungs. We know that epileptics may die in a sudden attack, and the autopsy may reveal a most astonishing condition of edema of the lungs. That edema of the brain might occur just as suddenly is, of course, a possibility, and one that is worthy of consideration. That intracranial pressure occurs in epilepsy is no novel theory. It has been advanced by a number of neurologists. That we may have a sudden increase of intracranial or extracranial pressure seems at least a possible conception.

---

# METHODS OF CONTROLLING HEMORRHAGE OF THE ORAL CAVITY.[*]

H. E. BELDEN, M.D., D.D.S.
NEW ORLEANS.

I have been asked to read a paper of interest to the medical as well as to the dental profession. The subject of the control of hemorrhage of the oral cavity may not be as important to the general practitioner as to the specialist, still, as the blood is the life fluid of the body, any suggestions to prevent its loss will, I think, be of interest to the profession at large, especially as the pathology and treatment of hemorrhage of the oral cavity do not differ materially from that of hemorrhage generally.

Fortunately, the operator is usually able to control the hemorrhage, but when the hemorrhagic diathesis is met and diseases of the capillary system, such as purpura and conditions associated with jaundice, a much more serious and complicated state of affairs exists.

The pathology of the hemorrhagic diathesis is not perfectly understood, and its actual cause can not always be satisfactorily explained. It is quite evident that the bleeding continues from a lack of harmony between the coagulation time of the blood and the contractility of the vessels.

There is a tube invented by Wright by which the coagulation time of the blood can be determined. The blood is sucked into the tube and its fluidity tested at intervals of less than a minute. The normal time for blood coagulation is from two to four minutes, but in the hemorrhagic diathesis, and in certain diseases, the time is so extended that a clot does not form quickly enough to engage the fibrin and act as a plug in the mouth of the vessels, but on the contrary, coagulating in from six to twenty minutes, the clot forming outside, acts as a vehicle to hold the wounded surfaces apart and facilitates the free oozing of the blood. Therefore, hemorrhage continues from a perverted relation between the constituents of the blood which are necessary to form a clot (fibrin ferment, fibrinogen and paraglobulin) and the contractibility of the circular muscular fibers of the arteries, veins and capillaries.

We know that the vasomotor system of nerves not only acts on the entire vascular system as a whole, but can control the blood to a circumscribed locality. So in the wounds caused by leeches bleeding continues for hours after the removal of the leech. Could this not be explained by the fact that the leech has produced a circumscribed vasomotor paralysis?

I think that an important point in the arrest of hemorrhage is that the physician impress the mind of the patient with his ability to control the hemorrhage, thus overcoming the effect that fear has on the vasomotor centers, as they control the contractility of the muscular coat of the vessels. I have noticed after the extraction of teeth that fear has a tendency to increase the hemorrhage. For example, a recent patient, not of the hemorrhagic diathesis, presented a marked case of surgical fright and after the extraction of a tooth bled profusely. Dr. J. A. Bodine, in a recent clinical lecture, cites a number of cases where death has been caused by fright. He says that the autopsy findings are exactly the same in cases of death from fright as in those from chloroform poisoning, the cause of death in both cases being a vasomotor paralysis; "that is to say, the nervous system lost control over the motor nerve leading to the blood vessels, and especially the veins of the body, and as a consequence the patient bled to death into his own tissue."

Hemorrhage is the escape of blood from its vessels. The simple term hemorrhage is used when the blood passes outside the body. If it escapes within the cavities of the body it is known as internal hemorrhage. When a small quantity of blood is forced or infiltrated into the tissues extravasation is produced. Internal hemorrhage may occur in two different ways: by rupture of the vessels and by diapedesis. In diapedesis the corpuscles of the blood escape into the tissues through the walls of the vessels.

The control of hemorrhage depends on its cause. The cause may be accidental, that is, come from injury or disease, or it may be intentional, as in operations or in the extracting of teeth. The hemorrhage may be arterial, venous or capillary, but is often a combination.

---

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

When there is injury to the arteries or large veins ligature is necessary, and when to the smaller veins and capillaries we resort to sutures, compression and styptics.

After the extraction of teeth, prolonged bleeding might occur from the dental artery becoming entangled in the ragged edges of the alveolus and its mouth being held open. In this case the bleeding would be red blood and spurt in jets. A drill run down into the cavity would disentangle the artery and stop the bleeding. In the same way it is possible that a nerve might become entangled. This would cause neuralgia. Relief would respond to the same treatment.

With proper treatment death is seldom a result of hemorrhage of the oral cavity. When it does occur it generally comes from the hemorrhagic diathesis or from accidental puncture to the larger vessels, as the jugular vein and carotid artery, or in cases of cancer and other malignant growths to capillary bleeding from the slough of unhealthy granulations. When the hemorrhage occurs from this cause the general condition of the patient is so serious that death is imminent anyway.

### MECHANICAL METHODS.

The treatment of hemorrhage of the oral cavity may be classed under three heads: Mechanical, medicinal and physiological.

The mechanical methods consist of direct application, as plugging or tamponing, compression, ligating the artery, torsion and suturing, position of the patient, etc. As hemorrhage of the oral cavity is usually capillary, compression is often all that is necessary to control it when properly applied.

In this connection I will describe the heroic treatment resorted to with good results by Dr. Fry of Hebron, Neb., of which I lately read in the *Dental Digest.* Tooth extraction was followed by hemorrhage in a patient subject to bleeding. He took an impression of the mouth in modeling compound, when cold, trimmed it to make an appliance that could be worn in the mouth, notching it to receive a strong bandage to be tied over the head. He then made a thin batter of plaster, added a pinch of salt and filled the appliance, putting it at once into the mouth and pressing it into place. When the plaster was set he added the bandage and tied it firmly. The socket had previously been packed with fluid extract of ergot. Immediate relief was given.

### MEDICINAL METHODS.

Under the head of medicinal methods of treatment we will consider the drugs applied locally, internally, hypodermically or intravenously. They have a systemic action and a direct action, one or both. In cases where a predisposition to hemorrhage is known or suspected before operating it is well to give systemic treatment of a nature depending on the general condition of the patient.

Among the new remedies which have appeared is calcium chlorid. This is recommended in doses of from 8 to 16 grains every two to four hours in all forms of persistent hemorrhage. It increases the coagulability of the blood, but when used for three days or more consecutively some authorities say it has the opposite effect.

Dr C. E. Vallis,[1] assistant dental surgeon in King's College Hospital, London, observed the case of a woman, aged 25, presenting the hemorrhagic diathesis, in whom the extraction of a tooth was followed by a hemorrhage lasting 36 hours. As the extraction of many carious teeth became necessary because of dyspeptic troubles, Dr. Vallis administered calcium chlorid in weak doses during eight days previous to the operation and extracted every tooth without hemorrhage. Dr. Vallis has since observed another case in which calcium chlorid has given the same satisfactory results. The disagreeable taste of this medicament and the slight tendency to constipation which it induces are the only inconveniences connected with its administration, even after a continuous use during a period of three to four weeks.

The following formula is ascribed to Bertignon:

℞. Crystallized calcium chlorid, 4 grams, or 60 grains.  
Syrup of mint .......... 30 grams, or 1 ounce.  
Distilled water ..........90 grams, or 3 ounces.

Dr. A. J. Ochsner gives a method of treatment in cases of hemophilia which consists of giving albumin in the form of whites of eggs. He says: "When from four to six whites of eggs are given three times daily there seems to be a very definite effect exerted on the clotting properties of the blood of these persons."

Another remedy which is creating general attention as a hemostatic is gelatin. It should be given in large doses, from 100 to 400 grains daily, and can be continued indefinitely. It seems to be contraindicated only in Bright's disease. It is doubtful whether it should be used subcutaneously or intravenously, as cases of tetanus have been reported from its use. We can understand this, for we know that gelatin is a medium used for propagating bacteria, and several authorities give it as their opinion that sterilization destroys its hemostatic properties. When applied locally an antiseptic should always be used in conjunction with it. It is a splendid systemic remedy and the good results consequent on its use are probably due to the nourishment of the vasomotor centers.

M. Marc Laffont and M. Andre Lombard conclude that "whenever some nutritional vice modifies the cryoscopic and other properties of the blood there may be glycosuria, an albuminuria, or a hemorrhage. Whether this syndrome is accompanied or not by an anatomic lesion, in a great majority of instances the lesion is curable if one attacks the cause. Gelatin seems to be the only agent capable of rendering the plasticity of the blood normal when administered in the dose of 225 grains daily. It is a harmless drug, and no contraindication to its use exists, and its administration should be prolonged."

The *Philadelphia Medical Journal* has this to say of adrenalin:

> Generally speaking, adrenalin, when locally applied, is the most powerful astringent and hemostatic known; also a very strong stimulant of the heart. It is non-irritating, non-poisonous and non-cumulative, as far as it has been observed. It is indicated in a condition produced by morphin and opium poisoning. It has produced good results in circulatory failure, in prevention of collapse of anesthesia and allied conditions. It is invaluable in carrying out bloodless operations in nose, ear, eye and throat work. Out of a great number of operations in which it was used, in only a few instances was sloughing after operation reported. The length of time required to control bleeding depends on its strength.

I have lately been experimenting with adrenalin in a small way. I have used it with good result to arrest the gingival hemorrhage which sometimes occurs in the removal of tartar from the necks of teeth and to check the bleeding which comes from the abrasion of the gums caused by the slipping of an instrument, sandpaper discs, emery wheels, etc., also in the removal of epulic tumors and after the extirpation of the pulp of a tooth. I have had good results with the use of adrenalin in conjunction with cocain in tooth extraction. I take a dram of the solution (1 to 1,000), add a grain of cocain (which gives about a 2 per cent. cocain solution) and inject a few minims into the gum. The cocain produces the usual local anesthesia, and the bleeding in almost every case has been extremely slight, and in some cases there has been no bleeding at all.

---

[1] Revue de Stomatologie, Paris, quoted in Dental Cosmos.

[2] Progrès Médical, April 5, 1902.

Bartholow says of turpentine: "It is a serviceable cardiac stimulant when the action of the heart is weak and the arterial tension low. In passive hemorrhages we possess few agents more generally useful. The indications for its use are a general debility, relaxation of the vessels and an impoverished condition of the blood. It need hardly be stated that active hemorrhage or a condition of plethora contraindicates the use of turpentine."

According to Garretson: "Depressing the action of the heart is under almost all circumstances a valuable means to arrest hemorrhage. To this end veratrum viride is always given with satisfaction. The dose is five drops for an adult, given in a tablespoonful of water. Conjoined with this, and in many instances quite capable of taking its place, is the hot foot-bath."

Dr. Arthur Masur, Breslau, Silesia, advises the use of powdered charcoal after tooth extraction where the hemorrhage requires special attention. In its review on current literature, the *Dental Cosmos* says: "His *modus operandi* is as follows: The alveolus, which is freely irrigated with pure water, is dusted with charcoal powder and to insure better adaptation of the charcoal to the bleeding capillaries it can be packed into the alveolus by means of cotton." There is also another and very easy way of carrying the powder into the alveolus—by means of a damp cotton tampon, which is made to take up the charcoal, and is then introduced into the canal. The powder is allowed to remain two minutes in the alveolus and is then washed out with a strong stream of water.

In cases in which it is desirable to leave a packing over night the use of iodoform gauze impregnated with charcoal is recommended, although the essayist states that he has never had to use this procedure, as he has always been able to arrest hemorrhage in these cases with the simple application of charcoal powder.

The action of the charcoal powder is supposed, to be merely a physical one, the closing up of the openings in the capillaries with the charcoal granules. Incidentally, it is also stated, the charcoal has the property of hastening the healing of the wound, and its union with the tissues of the wound is very intimate, as it takes a strong stream of water to dislodge it.

Dr. Spaark, in a French medical journal, advises a wash of five parts of water to one of chloroform to prevent hemorrhage after tooth extraction.

It is not necessary to consider the long list of hemostatics, as alum, ergot, tannin, etc. I decidedly object to the use of styptic iron, or strong solutions of nitrate of silver as hemostatics in the mouth because of the danger of sloughing and secondary hemorrhage with an enlarged bleeding surface. Nitrate of silver destroys tissue and causes much inflammation to the mucous membrane, and styptic iron makes an objectionable stain which is difficult to eradicate.

For persistent hemorrhage I recommend, when simpler remedies fail, a sharpened stick of lunar caustic once applied as an actual cautery to the bleeding sockets of extracted teeth.

In treating hemorrhage after tooth extraction my method is this: I have the patient rinse his mouth with an antiseptic solution, I then syringe the bleeding sockets where the teeth were with pure peroxid of hydrogen, then follow with an antiseptic solution. This stops the hemorrhage, but should it recur I repeat the above procedure and then apply as an actual cautery a sharpened stick of lunar caustic run down very carefully into the very bottom of each socket, then pack tightly with antiseptic cotton held in place with a compress. The peroxid of hydrogen dissolves more thoroughly the clots from the mouths of the vessels, gives oxygen to the blood and stimulates the muscular contraction, and Nature is allowed to assist itself. This is somewhat in line with the old theory of exposing the bleeding surface to the atmosphere, the edges of the wound being drawn apart, the clots washed away, and bleeding for the moment encouraged.

Oral operations should be executed rapidly.

When it is necessary to use an anesthetic in operating in the oral cavity, chloroform should be chosen (unless contraindicated) as it is not a heart stimulant, it does not increase the blood pressure, and so adds nothing to the liability to hemorrhage. During the anesthesia of the patient care should be taken not to allow any blood to get into the lungs by way of the trachea or pneumonia will follow. Necessary precautions against asphyxiation will, of course, be taken. This can be prevented by the Trendelenburg position, the use of the saliva ejector and judicious sponging with hot water or ice water.

Of the many operations that are performed in the oral cavity for correcting congenital deformities, for hypertrophy of the gums, for affections of the tongue, the hard and soft palate, extirpation of cysts, tumors and malignant growths, clipping the uvula and operations on the tonsils, none is more common than the last named. The following comprehensive definition is given by Dr. Richard Faulkner: "The term 'tonsil' is now applied to various collections of lymphoid glands situated at the oropharyngeal orifice, the anal orifice and at points throughout the alimentary tract." We have to consider only the oral tonsils. "It is now agreed that they are absorbent glands of lymphoid structure, their chief function being the generation of lymph cells or leucocytes" which "escape through the surface epithelium of the tonsil into the free cavity of the pharynx where they destroy micro-organisms and other deleterious agents."

In operating on the tonsils there is usually considerable bleeding, as they are very vascular bodies, deriving their blood supply from the tonsillar and palatine branches of the facial artery, the descending palatine branch of the internal maxillary and the ascending pharyngeal. Usually the hemorrhage can be controlled. Fatalities from hemorrhage after amygdalotomy have been caused most often from hemophilia, or accidental injury to the adjoining larger vessels. Although the internal carotid is situated about three-fourths of an inch back, cases have been recorded where it has been punctured. Broca reports a fatal case due to an anomaly of this vessel.

Some New Orleans men will remember an operation performed here by Dr. Bemis several years ago for abscess of the tonsil. He opened the abscess with a bistoury and the man went home. After several hours there was a gush of blood. Dr. Bemis was visiting patients and could not be found and the man bled to death. At the postmortem examination it was found that the abscess had disintegrated the walls of the carotid artery, and when the pressure exerted by the pus was relieved the walls of the vessel gave way.

The treatment for controlling hemorrhage after extirpation of the tonsils is ligating the larger vessels, where necessary; compression and styptics. Antipyrin is a favorite hemostatic in tonsillar surgery.

## DISCUSSION.

Dr. M. L. Rhein, New York City—The use of adrenalin in dentistry should be known to all. It is an important part of our pharmacopeia.

Dr. George F. Eames, Boston—I have used the extract of the suprarenal glands and the various preparations made from it for some time, and my experience with it has been very satisfactory. It is the most wonderful drug in the control of hemorrhage I have ever used. In some cases it does not seem to act, but these cases are so rare that they may be classed as cases of idiosyncrasy or peculiar unsusceptibility to the drug. I think Dr. Belden is correct in saying that it probably does enhance the effect of cocain, but that alone it is not an anesthetic. The peculiar diathesis of a patient should be considered, and the greatest caution used in the preparation of the patient for an operation which is apt to cause hemorrhage.

Dr. M. L. Rhein, New York City—I believe that we, as stomatologists, demand a much more profound anesthesia than the laryngologist in his work. I do not believe it is possible to obtain profound anesthesia, that is, local anesthesia, with the chlorid of adrenalin. Used in the nose or the eye a certain amount of anesthesia is unquestionably obtained, but the fact that it is not complete anesthesia, I think, blinds us to the anesthetic properties that it does possess. I think this anesthetic property is produced mechanically by the contraction of the capillaries expelling the nerve cells from the fibrillæ.

# THE INFLUENCE OF RESECTION OF THE CERVICAL SYMPATHETIC GANGLIA IN GLAUCOMA.

WILLIAM H. WILDER, M.D.
Assistant Professor of Ophthalmology, Rush Medical College, University of Chicago; Professor of Ophthalmology, Chicago Policlinic; Surgeon to the Illinois Charitable Eye and Ear Infirmary.
CHICAGO.

*(Concluded from p. 357.)*

## REPORT OF 61 ADDITIONAL OPERATIONS OF EXCISION OF SUPERIOR CERVICAL SYMPATHETIC GANGLION FOR GLAUCOMA.

Reports of these cases were sent to me through the kindness of the observers in response to the circular letter referred to. Lack of space prevents the publication of many of the details, but these have appeared in the Transactions of the Section on Ophthalmology of the American Medical Association.

### JAMES MOORES BALL. THREE CASES OF GLAUCOMA. FOUR OPERATIONS.[1]

No. 8.—Absolute glaucoma of right. M., aged 36, with R.V.=P. 1. L. V.=20/70. T.+3. After right sympathectomy tension fell to +1. Relief from pain for one year.

Nos. 9 and 10.—Simple glaucoma of both in woman aged 43. R.V.=0. T.+3. L. V.=P.1. T.+. Left sympathectomy, June 15, 1899, was followed by improvement in tension and vision. L. V.=F. 5 ft. T.n. Rt. sympathectomy, July 16, 1899, with temporary improvement in vision and tension. R. V.=hand movements. T.+1.

No. 11.—Sympathectomy in man 26 years old, gave immediate relief from pain in hemorrhagic glaucoma. No pain for 10 months.

### MELVILLE BLACK. ONE CASE.[2]

No. 12.—M., aged 35, had subacute glaucoma in left eye. L. V.=F. 1 ft. T.+2. Sympathectomy done Dec. 24, 1900, followed by immediate return to normal vision, normal fields and tension. This favorable condition has continued up to time of author's report to me, April 7, 1903.

### CALLAN. ONE CASE. BUPHTHALMUS; SECONDARY GLAUCOMA.

No. 13.—M., aged 25, with history of gradually failing sight. Highly myopic. Tension +1 in each eye. Right sympathectomy reduced the tension of right eye for a time, although it returned. The eye is not so large as before.

### D. H. COOVER. ONE CASE.[3]

No. 14.—Simple glaucoma in both. M., aged 65. R. V.=P.1. T.+3. L. V.=20/200. T.+2. Right sympathectomy caused slight improvement in tension and vision, but this lasted only four months.

### CUTLER. ONE CASE. CHRONIC IRRITATIVE GLAUCOMA. GREAT IMPROVEMENT.[4]

No. 15.—M., aged 56, with history of glaucomatous attacks for 8 years. Sclerotomy and also iridectomy had been done on the right. R. V.=F. 3 ft. T.+1. L. V.=0. T.+2. After eserin, R. V.=20/200. Right sympathectomy was followed by almost immediate improvement in vision and tension. R. V.=20/30. T. n. Last report of author says this improvement seems to be permanent.

### W. A. FISHER. ONE CASE. CHRONIC GLAUCOMA. NO IMPROVEMENT.

No. 16.—F., aged 62, with R. V. 12/200. T. n. Right sympathectomy had no effect on vision or fields, which gradually failed.

### HENRY GRADLE. ONE CASE. CHRONIC GLAUCOMA. DISEASE, STATIONARY.

No. 17.—F., aged 33, had simple glaucoma in both eyes. R. V.=20/40. T.+. Contracted fields. L. V.=0. Two iridectomies had been done on right eye, but had only delayed the disease. Right sympathectomy reduced the tension, which is normal after two and a half years. Central and peripheral vision unchanged.

### E. GRUENING. TWO CASES. ONE CHRONIC GLAUCOMA (BOTH). ONE OPTIC ATROPHY (BOTH).[5]

No. 18.—M., aged 50. Chronic glaucoma three years. R. V.=F. 2 ft. T.+1. L. V.=0. T.+1. Previous iridectomy. Right sympathectomy reduced tension to normal, and this remained so up to time of report. No change in vision.

No. 19.—M., aged 35. Double optic atrophy. R. V.=0. L. V.=20/30. Marked contraction of fields. T. n. Left sympathectomy had no effect on the vision. In both these cases there was paralysis of recurrent laryngeal, lasting many months.

### A. B. HALE. ONE CASE. SYMPATHECTOMY FOR THREATENED GLAUCOMA.

No. 20.—F., aged 48. R. V.=0. T.+, although two iridectomies had been done. L. V.=6/5. T.+. Fields contracted. Left sympathectomy was done to ward off an impending attack of glaucoma. Fields returned to normal.

### J. G. HUIZINGA. TWO CASES. 1. DOUBLE CHRONIC SIMPLE GLAUCOMA. DOUBLE SYMPATHECTOMY. IMPROVEMENT IN TENSION. 2. CHRONIC INFLAMMATORY GLAUCOMA. SYMPATHECTOMY. NO IMPROVEMENT.

Nos. 21 and 22.—M., aged 57. R. V.=P.1. T.+1. L. V.=6/20. T. n. Contracted fields. Double sympathectomy caused no material change in vision, but reduced tension to normal, where it remained.

No. 23.—M., aged 36. Double inflammatory glaucoma of several years' duration. R. V.=F. 3 ft. T.+3. L. V.=F. 3 ft.

---

[1] The Journal A. M. A., June 2, 1900.

[2] Ophthalmic Record, October, 1901.

[3] Phila. Med. Jour., March 16, 1900.

[4] Annals of Surgery, September, 1902.

[5] Ophth. Sec. N. Y. Academy of Med., November, 1901.

T.+3. Left sympathectomy had no effect on vision and patient became blind. Tension remained high.

### ARNOLD KNAPP. ONE CASE. DOUBLE CHRONIC GLAUCOMA WITH ATROPHY. DOUBLE SYMPATHECTOMY. SLIGHT IMPROVEMENT.

NOS. 24 AND 25.—M., aged 20. R. V.=16/200, after iridectomy. L. V.=12/200 (?). T.+2. Fields contracted.

After double sympathectomy vision in each improved to 20/200, and at time of last report, ten months later, R. V.= 20/200. T. n. L. V.=12/200. T.+.

### HARRY LA MOTTE. FIVE OPERATIONS. 1. DOUBLE ACUTE GLAUCOMA. RIGHT IRIDECTOMY, RECOVERY. LEFT SYMPATHECTOMY. RECOVERY.[6]

No. 26.—M., aged 27. Acute glaucoma in each eye relieved by eserin. R. V.=F. 16 ft. Iridectomy followed by improvement of vision to 20/50. L. V.=P.1. T.+1. Left sympathectomy was followed by great improvement. Eighteen months after operation, L. V.=20/20. T. n. Pupil normal.

Nos. 27 AND 28.—F., aged 38. Chronic inflammatory glaucoma of two years' duration. R. V.=20/30. L. V.=20/200. Slight cupping. No fields taken. Left sympathectomy was followed by marked improvement. L. V.=20/20. T. n. Right sympathectomy was done because vision of right eye suddenly failed. After operation vision returned to normal. Eighteen months later R. V.=20/20. T. n. L. V.=20/20. T. n. Some contraction of fields.

No. 29.—M., aged 43. Simple glaucoma of right eye. R. V.= F. 3 ft. T.+2. Right sympathectomy followed by improvement of vision to 20/70. This vision was retained fourteen months after, but tension was increased.

No. 30.—M., aged 40. Simple glaucoma for one year. R. V.= 20/30. T.+1. Fields contracted. L. V.=20/20. T. n. Right sympathectomy. During the operation the patient vomited and infected the wound. In spite of careful cleansing, the infection spread and he died of septic pneumonia.

### JOSEPH MULLEN. DOUBLE CHRONIC INFLAMMATORY GLAUCOMA. PREVIOUS IRIDECTOMY. RIGHT SYMPATHECTOMY WITH IMPROVEMENT.[7]

No. 31.—F., aged 48. History of bilateral iridectomy 23 years previously for acute glaucoma. R. V.=F. 5 ft. T.+2. L. V.=5/200. T.+2. Contracted fields. Right sympathectomy relieved pain, increased visual fields and reduced the tension to normal. At the time of the last report, nearly three years after the operation, R. V.=20/100. L. V.=20/70. Fields about the same as before operation.

### W. B. MARPLE. CHRONIC GLAUCOMA. SYMPATHECTOMY. NO IMPROVEMENT.[8]

No. 32.—V. 10/200. T.+1. Pupil dilated. After sympathectomy tension became normal and pupil diminished in size. Vision unchanged. Observation six months.

### H. R. PRICE. TWO CASES. DOUBLE SIMPLE GLAUCOMA WITH HEMORRHAGIC RETINITIS AND CHRONIC NEPHRITIS. RIGHT SYMPATHECTOMY. IMPROVEMENT.

No. 33.—M., aged 70. R. V.=P.1.; under eserin, 20/200. T.+. Hemorrhages in macular region. L. V.=20/200. T. n. Glaucoma cup, retinal hemorrhages. Right sympathectomy caused reduction of tension, and V.=20/100. Five months later R. V.=20/100. T. n. Fields enlarged.

No. 34.—M., aged 55. V. B.=20/40 to 20/70. T.+. Contracted fields. Iridectomy had been done five months previously. Right sympathectomy reduced tension. Patient under observation only 15 days.

### R. C. REESE. ONE CASE OF DOUBLE SIMPLE GLAUCOMA. IRIDECTOMY FIVE YEARS BEFORE. RIGHT SYMPATHECTOMY. IMPROVEMENT.

No. 35.—F., aged 58. R. V.=F. 10 ft. T.+. Fields contracted. L. V.=0. Iridectomy on both eyes five years before. Right sympathectomy reduced the tension, but did not improve central vision. One year later T.—. Fields and vision unchanged.

### E. C. RENAUD. SIX CASES (FIVE BILATERAL).[9]

No. 36.—F., aged 48. Right chronic inflammatory glaucoma. R. V.=20/200. T.+3. L. V.=20/20. T. n. Right sympathectomy followed by improvement. R. V.=20/50. T. n. Disappearance of pain. Improved condition remains, three years later.

Nos. 37 AND 38.—M., aged 52. Double simple glaucoma. R. V.=quantitative. T.+2. L. V.=large objects 6 ft. T.+2. Bilateral sympathectomy reduced tension to +1 and vision to 6/100. Improvement retained, two years after operation.

Nos. 39 AND 40.—F., aged 40. Chronic simple glaucoma of left. R. V.=20/20. T. n. L. V.=F. 3 ft. T.+3. Bilateral sympathectomy brought tension to normal. L. V.=F. 14 ft. Improvement continues two years after operation.

Nos. 41 AND 42.—M., aged 39. Chronic irritative glaucoma of right. R. V.=P.1. T.+2. L. V.=20/20. T. n. Bilateral sympathectomy relieved pain, improved right vision to F. 12 ft. T. n. Same improved condition one year later.

Nos. 43 AND 44.—M., aged 57. Acute glaucoma in right. R. V.=20/100. T.+3. L. V.=20/20. Bilateral sympathectomy. Pain and increased tension disappeared and pupil contracted. R. V.=20/40. Ten months later no return of trouble.

Nos. 45 AND 46.—M., aged 46. Right chronic irritative glaucoma. R. V.=20/200. T.+2. L. V.=20/20. T. n. Bilateral sympathectomy caused reduction of tension. R. V.= 20/100. Favorable result continues six months later.

### G. E. DE SCHWEINITZ. ONE CASE. DOUBLE CHRONIC CONGESTIVE GLAUCOMA. BILATERAL SYMPATHECTOMY. RESULT UNCERTAIN.

Nos. 47 AND 48.—M., aged 23. R. V.=shadows on temporal side. T.+2. L. V.=shadows. T.+2. Right sympathectomy caused contraction of pupil, which lasted only three days. Slight improvement of vision and tension. Left sympathectomy caused no change in tension, pupil or field. Patient was free from glaucomatous attacks for two months, then they returned.

### JOHN R. SHANNON. ONE CASE. DOUBLE SIMPLE GLAUCOMA. LEFT SYMPATHECTOMY. NO IMPROVEMENT.

No. 49.—F., aged 32. R. V.=15/200. T.—. L. V.=F. 3 ft, eccentrically. T.+1. Iridectomy had been done. Left sympathectomy caused no change in vision or tension.

### J. H. SHORTER. SECONDARY GLAUCOMA AFTER SYMPATHETIC INFLAMMATION. LEFT SYMPATHECTOMY. SLIGHT IMPROVEMENT.[10]

No. 50.—M., aged 20. Lost right eye from trauma. Glaucoma in left eye following sympathetic ophthalmia. L. V.=F. 3 ft. T.+2. Left sympathectomy. L. V.=F. 6 ft. T. n. Fields slightly increased. Improvement continues.

### ELMER G. STARR. DOUBLE SIMPLE GLAUCOMA. POSTERIOR SCLEROTOMY. BILATERAL SYMPATHECTOMY. MARKED IMPROVEMENT.

Nos. 51 AND 52.—F., aged 63. Disease controlled for nine months with eserin; then sudden reduction of vision. R. V.= F. 4 ft. T.+3. L. V.=F. 4 ft. T.+3. Sclerotomy of right eye improved vision to F. 18 ft. After bilateral sympathectomy R. V.=20/50. T.+1. L. V.=20/50. T. n. Pupils normal. Improvement persisted up to time of report, six months later.

### GEORGE F. SUKER. FOUR CASES, FIVE OPERATIONS.[11]

No. 53.—M., aged 70. Double chronic glaucoma. R. V.=0. Absolute glaucoma. L. V.=20/200. T. n. Iridectomy of left in 1898. Right sympathectomy produced no change in fields, tension or vision.

Nos. 54 AND 55.—M., aged 65. Double simple glaucoma. R. V.=F. 8 ft. T.+2. L. V.=F. 10 ft. T.+. Fields contracted. After bilateral sympathectomy fields enlarged slightly and then contracted to less than before. No improvement.

No. 56.—F., aged 67. Chronic inflammatory glaucoma of left. R. V.=20/40. T. n. L. V.=20/100. T.+2. Nasal contraction of field. Left sympathectomy caused enlargement of fields and normal tension. L. V.=20/100. Improvement continued until patient's death, three years later.

No. 57.—M., aged 58. Absolute glaucoma of right. Chronic inflammatory glaucoma of left. R. V.=0. T.+3. L. V.=20/80. T. n. Fields normal. Iridectomy of left had been done some time before. Right sympathectomy produced no effect on tension or vision.

### DAVID WEBSTER. ONE CASE. RIGHT SIMPLE GLAUCOMA. LEFT ABSOLUTE GLAUCOMA. RIGHT SYMPATHECTOMY. IMPROVEMENT.

No. 58.—M., aged 49. R. V.=20/50. T.+. Field slightly contracted. L. V.=0. T.+3. Right sympathectomy. Fields improved. R. V.=20/30. T.—. One year later R. V.=20/50. T. n. Fields as before operation.

### JOHN E. WEEKS. FIVE CASES, SEVEN OPERATIONS.[12]

No. 59.—F., aged 56. Chronic glaucoma of right. R. V.= F. 1 ft. T.+2. Fields contracted. L. V.=20/20. T.+1. After right sympathectomy fields increased markedly, but tension remained plus. Five weeks later R. V.=20/70. T.+1. Some weeks after an acute attack of glaucoma in the right eye necessitated iridectomy after which R V.=F. 7 ft.

Nos. 60 AND 61.—M., aged 70. Simple glaucoma of right (absolute), subacute glaucoma, left. R. V.=P.1. T.+2. L V.= 20/40. T.+2. Fields contracted. Bilateral sympathectomy relieved the tension in the right eye, and markedly improved the left. L. V.=20/20. Fields much improved.

No. 62.—Simple chronic glaucoma of left. Absolute glaucoma of right. R. V.=0. T.+3. L. V.=20/70. T.+. Fields contracted. After left sympathectomy L. V.=20/30. T. n. Three months later. L. V.=20/20. T.+. Fields increased.

Nos. 63 AND 64.—M., aged 30. Simple glaucoma of both. R. V.=20/40. T.+1. Right sympathectomy reduced tension to normal, but excited acute attack in left eye. L. V.=1/200. Left sympathectomy not successful, for tension of left eye remained high and iridectomy was done. Later iridectomy was done on right eye for increased tension. Last report R. V.= 20/40. T. n. L. V.=F. 17 ft.

No. 65.—M., aged 40. Simple glaucoma of both. R. V.=0. T.+3. L. V.=F. 5 ft. T.+. Iridectomy had been done. Left sympathectomy followed by improvement in tension and vision. Three months later L. V.=20/200. T. n.

### MEYER WIENER. TWO CASES.

No. 66.—F., aged 50. Chronic inflammatory glaucoma right. R. V.=F. 12 ft. T.+2. L. V.=0. Right sympathectomy caused no change in vision or tension.

No. 67.—F., aged 45. Chronic simple glaucoma of right. R. V.=6/200. T.+1. L. V.=6/6. T. n. Right sympathectomy. No improvement.

### H. W. WOODRUFF. ONE CASE. SIMPLE GLAUCOMA OF LEFT.[13]

No. 68.—M., aged 29. R. V.=0. Result of an injury. L. V.= 20/40. T.+. Fields contracted. After left sympathectomy T. n. and improved vision. Later central vision improved to 20/20. Six months later return of all symptoms and iridectomy was done with a final result of L. V.=20/70. T. n. Contracted fields.

We have here records of 68 operations done on 54 cases, i. e., 14 were bilateral. Of these operations, 38 were for simple glaucoma; 16 for chronic inflammatory glaucoma; 4 for subacute glaucoma; 3 for acute glaucoma; 4 for absolute glaucoma; 2 for hemorrhagic glaucoma; 1 for buphthalmus.

Of these five operations were preventive, one by Hale (20), four by Renaud (40, 42, 44, 46). No glaucoma up to time of reports. One death occurred (30). Of the 38 operations for simple glaucoma, 14 gave no improvement whatsoever. Five were temporarily improved for periods ranging from fifteen days to eight months, but had recurrent attacks that necessitated iridectomy or caused loss of the eye. Fifteen were improved as long as they were under observation, for periods of from two months to two years. Of these three were stationary (5, 17, 58); one died (30); six remained unimproved after iridectomy, but improved after sympathectomy (17, 18, 24, 34, 35, 65).

Concerning the 15 that were improved, No. 9 showed slight improvement; No. 18 improvement as to tension; previous iridectomy had been done; observation, one year; No. 24, improvement as to central vision and tension; No. 29, marked improvement; observation, fourteen months; No. 34, previous iridectomy had been done; improvement after sympathectomy, but patient was only under observation for fifteen days; No. 35. previous iridectomy, after the sympathectomy the tension remained minus; Nos. 37 and 38, slight improvement as to vision, but tension is still plus; time of observation, two years; No. 40, improvement as to tension, slight improvement as to vision; time of observation, twenty months; Nos. 51 and 52, marked improvement in tension and vision; posterior sclerotomy had been done without effect; time of observation, six months; Nos. 62 and 65, previous iridectomy; marked improvement in tension and vision; time of observation, four months; Nos. 4 and 6 showed marked improvement, and have been under observation for nine months and four months, respectively.

Of the 16 operations for chronic inflammatory, 6 showed no improvement; 3 showed improvement for periods from two to three months (2, 31, 50); 4 were improved as long as they were under observation; 1 (45) five months, 1 (15) eighteen months, 1 (41) one year, 1 (36) three years.

Of these 1 (15) had not been benefited by iridectomy, but greatly improved by sympathectomy; eighteen months under observation; 3 (20, 42, 46) were preventive, and disease had not appeared at three months, eight months and one year after operation.

Of the four that showed improvement, No. 15 is the most interesting, because an iridectomy failed to check the disease, but sympathectomy produced marked results in central and peripheral vision. Time of observation, eighteen months.

In No. 36, improvement in central vision continued after three years, tension slightly plus; in No. 41, improvement continues after one year; in No. 45, vision and tension were improved and pain was relieved; time of observation, five months.

No. 20 is interesting in that the operation was done for threatened glaucoma.

In Nos. 42 and 46 it is not stated whether the bilateral operation was done to influence more profoundly the diseased eye or to prevent the occurrence of the disease in the perfectly sound eye. The same may be said concerning Cases 39 and 44, in which one eye was normal in every respect.

Of the 4 operations for subacute glaucoma, 1 (12) cured at the end of two and a half years (Black); 2 (27, 28) remained well at end of fifteen months (LaMotte); 1 (60) remained improved after observation of four months (Weeks).

Of the three operations for acute glaucoma, 1 (26) recovered; observation, fifteen months (LaMotte); 1 (43) improved; remained so after nine months (Renaud); 1 (44) preventive; no attack occurred.

Of the four operations for absolute glaucoma, 1 (8) improved as to pain; 3, no improvement and no change.

Of the two operations for hemorrhagic glaucoma, 1 (11) improved as to pain; 1 (33), improved vision during time of observation, five months.

One operation for buphthalmus had no effect.

SUMMARY.

| Form of Glaucoma. | No. of Cases. | Improved. | Temporarily Improved. | Stationary. | Unimproved. |
|---|---|---|---|---|---|
| Simple chronic | 38 | 15 | 5 | 3 | 15 |
| Chronic inflammatory | 16 | 4 | 3 | 3 | 6 |
| Subacute | 4 | 3 | 1 | .. | .. |
| Acute | 3 | 1 | 1 | 1 | .. |
| Absolute | 4 | 1 | .. | .. | 3 |
| Hemorrhagic | 2 | 2 | .. | .. | .. |
| Buphthalmus | 1 | .. | .. | .. | 1 |
| | 68 | 26 | 10 | 7 | 25 |

After these 68 operations miosis is mentioned as occurring 40 times, and this condition remained for periods ranging from two days to three years. In most cases it seems to be permanent. It is mentioned that in 34 cases the tension was reduced to normal, and in 9 others it was much lower than it was before the operation. As to the effect of the operation on the lid, conjunctiva, face, etc., ptosis occurred in 36 cases and lasted for periods ranging from thirteen days to one year. This, like miosis, is one of the most constant phenomena. Conjunctival congestion was noted in 19 cases, lasting for a variable time, usually not longer than a few days. One case persisted for three months. Increased lachrymation was observed in 18 of the cases. This was of short duration, but in one case lasted three weeks. Congestion of the face on the side operated on was observed six times, in one case lasting three months.

Neuralgia and hyperesthesia of the side of the face operated on was noted in six cases, lasting in one case for one year. Anesthesia of the face or neck on the operated side was mentioned in only two cases; in one of them it lasted three months. Hoarseness or aphonia occurred in 8 cases, lasting for a variable time, from one week to three weeks. In two of the cases dysphonia was the result of paralysis of the recurrent laryngeal, and lasted in one for nine months and in the other for two years. Dysphagia was observed in 5 cases as a result of the operation. This symptom lasted only two or three days, except in one case, in which it persisted for six months. In one case (5), for a period of several days after the operation, the patient had mild hallucinations.

The results exhibited in this series of cases, at first glance, do not seem as favorable as those presented by Rohmer,[14] who drew conclusions from a study of 74 cases collected by Bichat, to which he added 20 of his own. On these 94 cases, 114 operations were done. The following table gives a summary of the results of their analysis of these cases:

| Form of Glaucoma. | No. of Cases Operated on. | Improved. | Negative. | Worse. |
|---|---|---|---|---|
| Simple chronic | 43 | 36 | 5 | 2 |
| Chronic inflammatory | 34 | 23 | 10 | 1 |
| Subacute | 14 | 6 | 6 | 2 |
| Acute | 9 | 4 | 5 | .. |
| Absolute | 3 | 1 | 2 | .. |
| Hemorrhagic | 5 | 5 | .. | .. |
| Hydrophthalmus | 6 | 4 | 1 | 1 |
| | 114 | 79 | 29 | 6 |

The statistics of Ziehe and Axenfeld,[15] who studied the results in 55 cases, agree with this in the main, for many of the cases in each series are the same. Unfortunately, many of these cases, as in the present series, either do not give the final result, or were under observation such a short time as to make any statement as to the final outcome impossible. Again, in studying them, it is seen that the records of many of them are far from exact.

However, to quote Axenfeld: "There is obtained by this operation in a certain proportion of cases of simple glaucoma, a definite and important result, and, in some instances, there has been a decided improvement, even where a previous iridectomy had failed." Such cases as those reported by Grunert,[16] Demicheri,[17] Cutler, Starr[18] and Weeks,[19] in which sclerotomy and iridectomy had been unsuccessfully performed, and sympathectomy accomplished not only reduction in tension but improvement in both central and peripheral vision, speak strongly in favor of the operation in certain cases.

As was said in the beginning, I feel that positive conclusions are not yet to be reached, and will not be until more carefully selected cases can be studied for longer periods of time.

The operation in itself, while a major one, is not to be considered one of unusual danger, and with modern technic should show a very trifling mortality. The death recorded in our present series was purely accidental, and might have occurred in any other operation on the neck. With such brilliant results before us as are presented in certain cases on record, we must agree that sympathectomy is not an operation to be condemned too hastily. It certainly is not fair to condemn it when it fails to restore sight to an eye that has suffered so long from glaucoma that it is blind from atrophy of the nerve, or when it fails to check pain in an eye that is hopelessly lost from absolute glaucoma.

If it is to be compared with iridectomy at all, it should be given an early trial in any form of the disease in which it is applicable.

The statistics up to date seem to indicate that the simple chronic form is the one most suited for it, next to the hemorrhagic form, if that can be determined. As a guide for my own practice, I should feel very much like following Abadie[20] when he says: "In acute forms of glaucoma and in subacute with intermissions, practice first iridectomy, and if it fails do sympathectomy. In simple glaucoma use miotics twice a day; if they suffice, continue them. If, in spite of their systematic employment the vision fails, do sympathectomy."

## DISCUSSION

### ON THE PAPERS OF DRS. DE SCHWEINITZ, WILDER, BALL AND WEEKS.*

**Dr. Melville Black**, Denver—It has been a great privilege to listen to these papers, and I am sure we must all feel that we know more about the subject now than we did before. It is a particularly interesting subject to me, and I believe that we can feel from the statistics presented so far that the operation is one of value. It is an operation, however, that is to be properly considered. My own personal feelings are that it should not be performed as a last resort, but really as a first one. The statistics of the operation will be vitiated, and have been up to the present time, by attempting it as a procedure where nothing could possibly be of any benefit. If sympathectomy is to be of any service it must be before the filtration angle is blocked or closed. If this angle has been occluded it is a question if the operation can be of any permanent benefit. It would seem to me that where eserin has a prompt action in relieving tension and pain and in improving vision and bringing up the field, that the action of sympathectomy should be correspondingly good and more permanent; that is, we can liken somewhat the after-effects of sympathectomy to the effects we obtain from the use of eserin. Of course, we can not continue the use of eserin indefinitely, and if we have in this procedure something permanent, it is certainly of great value.

* The papers of Drs. de Schweinitz, Ball and Weeks appeared in THE JOURNAL January 30, and the paper of Dr. Wilder was begun in THE JOURNAL February 6.

I am inclined to believe that the results will not be as permanent as we would wish. With watching this one case of mine it has seemed to me that the eye is getting from some source more and more sympathetic nerve power. The ptosis is subsiding; the eye is no longer congested; the pupil is becoming more nearly the size of its fellow; at one time we had .50 diopter of myopia—we now have .50 diopter of hypermetropia. Therefore it would seem to me that this eye is gradually regaining its sympathetic nerve supply.

It would seem to me that where this operation is done a sufficiently extensive procedure should be adopted to insure as much cutting off as possible of the sympathetic nerve supply; and that therefore it would seem well to excise the middle ganglion with the superior. Any one who has watched the operation will have noticed how associated these two ganglia are and how easy it would be in removing the superior alone to have a supply from the middle. Dr. Freeman, Denver, has operated on ten cases, removing both ganglia. Only one of these operations, however, was done for glaucoma. He has seen in his practice no undesirable results following this procedure, and his opinion was, as I obtained it, that the operation was a comparatively easy one unless the subject were an enormous, bull-necked individual. The scar resulting is slight, provided a buried suture is placed, and in the course of three or four months it is scarcely possible to find a scar. The only thing of serious consequence that may follow is neuralgia, and that seems to be due to rather unnecessary bruising of some of the nerves that come off through the vertebræ.

I think that this operation is one that we should all consider, so far as our statistical results present, as being one of value, and while we should not embrace it with too much enthusiasm, yet at the same time we should give it the benefit of the doubt as being of some service, and we should not depend on the operation only where iridectomy has failed and all other known procedures have failed. It should be tried first, not last. Several cases have been reported where the operation has been of value even after iridectomy has failed. This might lead us to think that in certain cases ganglion excitation existed and that the removal of the ganglia relieved that irritation, which might have been the beginning cause of the glaucoma.

Dr. G. C. Savage, Nashville, Tenn.—I believe we have some reasons for holding the opinion that the sympathetic nervous system is the source of power that Nature has given us for the correction of astigmatism. That in early life every astigmatic eye has the power of correcting a considerable portion of its defect, if not all, is now universally believed. One must certainly be convinced that Nature has furnished some power by which this defect is remedied. It is not in Mueller's muscle, nor in the third nerve. In my own case atropin and homatropin were used to uncover my error of refraction, but both failed. I am to-day wearing a lens four times as strong as that with which I commenced. Each time the increase was made I got additional relief, until finally the full strength lens was given. I happened to be in Dr. Burnett's office in 1889 and my corneal astigmatism was the same then as it is to-day. A considerable portion of my astigmatism was corrected by some means within the eye in spite of a mydriatic.

Only two meridians of any cornea that is astigmatic have a focus—the two principal meridians. One is the meridian of greatest curvature, and the other of least curvature. When Mueller's muscle, supplied by the third nerve, contracts, the lens is made more convex, and the two foci are brought into definite relation with the retina, but not closer to each other, hence they are not made to fuse. The other muscle in the ciliary body is that of Bowman, which I believe is controlled by the superior cervical sympathetic. If under the influence of the sympathetic some fibers of Bowman's muscle can be thrown into contraction while others are not, it would result in tilting of the lens. When the lens is tilted on an axis in the plane of the meridian of greatest curvature the two foci are made to approach each other, and if the tilting be far enough they are fused into one. The power given us by Nature for the correction of astigmatism is in Bowman's muscle, and I believe it acts under the influence of the superior cervical sympathetic ganglion.

Dr. George F. Suker, Chicago—I maintain that the relation between any form of glaucoma and the sympathetic nervous system, including the cervical, is still open for considerable debate. We do not to a certainty know the physiologic tracts of the cranial sympathetic fibers in all instances; nor do we know whether or not these sympathetic fibers decussate in all individuals as do the cranial nerves proper. The ganglion of Ribes, situated on the anterior communicating artery, is not present in every instance according to some anatomists. Yet, if it is present, it is here where the cephalic extremities of the ascending branches of the cervical sympathetic fibers join and cross. This point may explain why, in some cases, a unilateral excision of the ganglion is of only temporary benefit. For, if this communication does exist, it is not unreasonable to suppose that the opposite side is furnishing the abnormal stimulus through the intact cephalic ends of the excised side. Just as the other corresponding nerve centers take up the function of its fellow when it is destroyed, so may the sympathetic system, by means of its ganglia, do the same. This fact may and does explain why in Dr. Black's case there was a return of the function of the sympathetic with its detrimental effects on the side operated on.

There is no justification in excising the middle cervical ganglion as well as the superior for glaucoma. However, it is very necessary to cut the connecting cord and excise that ascending branch of the middle ganglion which connects with the ascending fibers of the superior ganglion high up in the neck. It is only the cavernous and carotid plexuses of the superior ganglion which have any relation to the eye. For reasons already stated it is necessary to completely destroy the connections between these two ganglia.

The ciliary or lenticular ganglion must also be considered if we expect to explain the relation of the sympathetic fibers to glaucoma. For, it is the upper two-thirds which contain sympathetic filaments supplying the anterior segment of the eye. The lower third of this ganglion receives a branch of the third nerve. Furthermore, the sympathetic fibers in the rami communicantes, which are closely associated with the fifth nerve and enter the eye along with the optic nerve, must be seriously considered. These branches also supply the segment of the eye around which centers the pathology of glaucoma. The experiments of Anderson,[1] Delens[2] and Rohmer[3] with the sympathetic supply of the eye are to be considered in solving its relation to glaucoma. Especially are these various sympathetic fibers and ganglia to be surgically thought of in glaucoma, for we know that the superior cervical is frequently, if not invariably, histologically changed. What is true for this ganglion may hold true for the others also.

In no case of glaucoma have all the sympathetic fibers and ganglia, on one or both sides, supplying that eye ever been severed. Experimentally they have, then tension was reduced and the iris remained contracted, both permanently.

It is questionable, as Dr. de Schweinitz has stated, whether any trophic actions can be ascribed to the sympathetic nerves. As yet we are not in a position to attribute any trophic functions to certain kind of nerves. The untoward effects which follow the extirpation of the superior sympathetic ganglion are trivial and not permanent. The only one to receive any consideration is the enophthalmus; this, however, is only slight and does not supervene in every case.

The statistics here given by Drs. Wilder and Ball show that the operation was undertaken in such cases as might well be called desperate. Therefore, the operation has not been awarded a fair trial. There is no doubt that in well-selected cases it will accomplish what an iridectomy will not. In my hands the operation has been successful in a few instances, as the reports of the cases show. What good the excision of the ganglion will do in optic atrophy is yet debatable. In the case on which I operated I did obtain a decided benefit, though temporary. Dana of New York tried it in a case of tabetic atrophy, though with what success I could not ascertain.

[2] Bull. de la Soc. de Chirurgie, April, 1902.
[3] Annals d'Oculistique, July, 1902.

Several years ago I was quite enthusiastic concerning the future of sympathectomy; but of late I have become very conservative, as my paper before this Section in 1901 clearly demonstrated.

Dr. Edward Jackson, Denver—The trend of the papers would seem to indicate that we are not in a position to decide many questions in reference to the use of excision of the sympathetic ganglia in glaucoma. Yet in going over the literature one point seemed pretty clear to me, and that is confirmed this morning. Dr. Black broached it when he said that the case in which excision does good is the case favorably influenced by eserin. I think there is enough evidence now, although it lies in a very small minority of the published cases, to indicate that sympathectomy, or excision of the ganglia, will do good in the cases that would be benefited by iridectomy. If we consider apart those cases in which iridectomy would have been a hopeful operation, I think the record for sympathetic excision is very promising. That might appear to be saying that operations on the sympathetic had no place where iridectomy is an established operation, but such is not the case. I think sympathectomy may be of value in an important class of cases; as where one eye has been lost and it is difficult to get the patient to consent to an operation on the other eye at the stage where the operation is most hopeful, where iridectomy can not be done, or the patient can not be induced to have it done, and yet where if it were done the probabilities would be in favor of it, we are now justified in urging operation on the sympathetic. The cases where iridectomy is reported to have been done and no good accomplished, and then sympathectomy has been efficient, might seem to lead in another direction. I have seen one case where iridectomy did no good and sympathectomy afterwards restored vision. But it may be that in some of these cases where iridectomy is said to have been done it has not been a broad, complete excision of the iris, which I believe necessary to give iridectomy its best effect.

Dr. G. E. de Schweinitz, Philadelphia—The members of the Section must have realized that it has been impossible in presenting a résumé of the physiologic side of this question to read in detail the experiments and observations on which the conclusions were based. For example, I did not have time to discuss the question of the pupil-dilating fibers which do not run in the sympathetic system, although in the extended paper I have made reference to them. I confess that I am distinctly skeptical as to the permanent value of sympathectomy in the treatment of glaucoma, although I realize that a certain number of brilliant results have followed this operation, and also realize that at present our statistical information is to a certain extent misleading, because the operation has in most instances been utilized as a last resource, and therefore the results of prompt interference according to this method are not at our disposal, or, at least, at our disposal in a most limited degree. Dr. Black's idea that if the effect of eserin on a glaucomatous eye is good, we may reason that sympathectomy would likewise be followed by good results, does not seem to me to be an entirely safe guiding principle. Eserin accomplishes its good in those cases in which it is able to release the filtration angle from blockade by contracting the pupil and drawing the periphery of the iris away from the danger of adhesive inflammation to the structures in the filtration angle. Now, in a certain number of cases, perhaps in the majority of cases in which sympathectomy has been performed, the process has been a chronic one in which pronounced blockade in the filtration angle was lacking, cases in which it is possible that there may have been a hypersecretion of the intra-ocular fluids, or an increased serosity. Cases of acute glaucoma are just the ones in which strong solutions of the myotics give frequently the best temporary relief, and they are certainly not the ones in which the sympathectomy is advisable, at least, as far as our present knowledge goes. I entirely agree with Dr. Suker, and all physiologic investigation is on his side, that it is not necessary to excise the middle ganglion. Excision of the superior ganglion, which is the relay station for the sympathetic nerve supply for the whole of the head, accomplishes everything that can be accomplished by this operation in so far as the relief of glaucoma is concerned. Referring to Dr. Savage's interesting observations on his own eyes, I may say that in the extended paper I have reviewed at some length the action of the sympathetic on the eye in its relation to accommodation and refraction. The evidence is exceedingly contradictory, and the whole subject is an inviting one for further research.

Dr. Wm. H. Wilder, Chicago—The report of the histologic appearance of the ganglia that were excised was not read, but if any of you are interested in seeing the specimens they are on exhibition in the next room. The ganglia do not show, as was stated by Dr. Weeks, any increase in connective tissue, but one can see in the specimens that there is an increase in the adventitia of the coats of the vessels and that there is considerable pigment in the cells.

One important question comes up in connection with the statement made by Dr. Black, that he considers that where there is good contraction of the pupil with eserin sympathectomy would be indicated; one case I have reported, Case 7, makes me doubt seriously whether we should resort to sympathectomy or to iridectomy first in these cases of simple glaucoma. I am skeptical about the value of iridectomy in true simple glaucoma, particularly where the anterior chamber is of normal depth, and it is in such cases that sympathectomy should do good. We can not place much reliance on either procedure, but perhaps we can rely as much on sympathectomy as on iridectomy. The unpleasant experience in Case 7 suggests that possibly it might be safer to do the iridectomy first. In spite of the sympathectomy in this case, the tension and the central vision remained the same; the peripheral vision continued to contract until it was as though the patient were looking through a narrow gun barrel. I did an iridectomy and there was hemorrhage from the choroid and the eye was lost. A similar case has been reported by Mohr. However, in such a case the same accident might happen if sympathectomy had not been done.

It is not fair to condemn the operation when it fails to restore an eye that has atrophy of the optic nerve, or when it fails to relieve pain in an eye lost from glaucoma. It should be given an early trial. The statistics indicate that the simple chronic form is the most suited for the operation, with the hemorrhagic form next.

Dr. J. M. Ball, St. Louis—As to the pathologic changes found in the ganglia, we have found in exophthalmic goiter that the same pathologic condition exists. It is the same in each of these conditions—an overgrowth of connective tissue, a separation of the nerve elements and the presence of pigment. I have been told by Dr. Fish of St. Louis that the same changes are found in multiple sclerosis and in tabes.

# NEW ASPECTS OF YELLOW FEVER ETIOLOGY

## ARISING FROM THE EXPERIMENTAL FINDINGS OF THE LAST THREE YEARS.*

CARLOS J. FINLAY, M.D.
HAVANA, CUBA.

In the light of modern researches yellow fever must now be considered as a disease produced, in individuals belonging to certain human races, by a two-host, microscopic, perhaps ultra-microscopic germ, endoparasite of the female of a particular species of mosquito—the *Stegomyia fasciata* (Theobald).

This germ pursues its parasitic existence in the body of the infected stegomyia during a period of 59 days, as experiments have proved, and probably, under ordinary circumstances, till the death of its mosquito-host. In order, however, that it may complete its life cycle, secure the perpetuation of its species and find its way into the body of other healthy stegomyias, it is necessary that it should penetrate, through the bite of the infected insect, into the body of a person who is liable to undergo an attack of yellow fever.

---

* Read at the thirty-first annual meeting of the American Public Health Association, Oct. 28, 1903, Washington, D. C.

After parting from its mosquito-host, the germ apparently goes through certain evolutions in the body of the non-immune, and, after the lapse of from three to five days, as a rule, brings about the attack of yellow fever. What the character of those evolutions are can only be surmised. We do know, however, that while the sojourn of the parasite in the body of the infected stegomyia may continue during at least two months without perceptibly affecting the longevity or the functional activity of its insect-host, its presence in the human host reveals itself only during a short number of days, disappearing, apparently by the end of the sixth day of the dangerous illness which it occasions, without leaving any other trace of its brief sojourn in the human host except the immunity which a first attack of yellow fever confers. The person thus immunized can thereafter receive with impunity the bites of any number of infected stegomyias and becomes incapacitated from contributing again to the perpetuation of the germ.

Since the first day of the attack of yellow fever (as early as the ninth hour in one of Dr. Carroll's cases), any healthy stegomyia that bites the patient is liable to become infected, so that a new life cycle will be opened for the germ in the newly infected stegomyia. Thus by alternately passing from the human to the mosquito-host and vice versa, the yellow fever germ has now lived during several consecutive centuries in tropical America, where both the aborigines and the European invaders belonged to susceptible races.

Now let us consider the probable character of the evolutions which the yellow fever germ undergoes in the body of the human host. Bearing in mind the fact that other two-host protozoa, such as the malaria parasite, lead during several consecutive months a parasitic existence, multiplying by schizogonia, forming schizonts, merozoits and, after a while, also gametes, in the body of their permanent host, and are unable to accomplish the sexual reproduction indispensable for the perpetuation of their species, unless they pass into the body of a second host (the Anopheles, in the case of the malaria parasite); bearing this in mind, are we not justified in supposing that the yellow fever parasite, being unable to accomplish this sexual reproduction in the body of its permanent mosquito-host, can only succeed in doing so by passing into the body of a non-immune human being after some of its elements have reached a stage of sexual differentiation corresponding to the gametes of malaria?

There is, moreover, another important consideration which may be adduced in support of this interpretation. The large tertian parasite, untreated, may continue for many months in the body of infected persons without immediate danger to the patient, whereas Grassi, I am informed, has found all the anopheles, in the Roman marshes, free from parasites during the winter season, so that all the infected ones must have died in consequence of their infection (corresponding to the phase of sexual reproduction of the parasite), and he attributes the renewal of the malaria epidemic in the following spring to the survival of the parasites in the human permanent host, in whose body only schizogonic phases are accomplished. This shows that the act of sexual reproduction is attended with more dangerous consequences for the host in which it is accomplished than are the various schizogonic phases of the same germ, a result which I had already surmised by reason of the greater metabolic changes which must accompany the sexual reproduction as compared with the schizogonic multiplication.

If it be admitted, therefore, that the penetration of the germ into the body of the non-immune is intended for the accomplishment of its sexual reproduction, and also that the analogy between it and the malaria parasite holds good, with the difference only that the latter accomplishes this act in the anopheles mosquito while the yellow fever germ does so in the human host, the following important inferences may be drawn.

The minimum number of days (estimated at 10 or 12 by the Yellow Fever Army Board) which must elapse, after the stegomyia has bitten a yellow fever patient, before the infected insect is able to inoculate the disease through its bites, must represent a series of transformations in the body of the contaminated mosquito, including:

(a) Introduction of young sporozoits sucked up with the blood of the patient.

(b) Growth of the sporozoits to adult age.

(c) Formation of schizonts and merozoits.

(d) Formation of gametes.

While, in the body of the non-immune, counting from the moment of his inoculation by the infected stegomyia, the following stages are likely to take place during the period of incubation:

(a) Localization of the gametes in appropriate sites.

(b) Fecundation of the macrogametes by the microgametes of the yellow fever germ.

(c) Formation of the oökinet and development of the oöcyst in appropriate cells (endothelial?).

(d) Discharge of free sporozoits of yellow fever into the circulating blood (perhaps too small to be recognized with the microscope).

(e) Development of the toxemic symptoms characteristic of the invasion of yellow fever, in the inoculated non-immune.

In calling your attention to this correlation of ideas, my object is not to make a display of fanciful conceptions, but simply to comply with my belief that unless we map out for ourselves some working hypothesis of this kind we shall continue groping in the dark, with little hope of completing our knowledge of the yellow fever etiology.

---

# THE PRESENT STATUS OF THE URIC ACID QUESTION.*

WALTER BAUMGARTEN, M.D.
Assistant in Medicine, The Johns Hopkins University.
BALTIMORE.

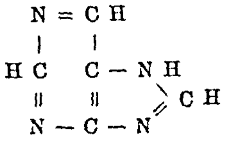
The work of recent years on uric acid metabolism has completely set aside the theory once universally accepted that in mammals uric acid is a product of the metabolism of all proteids, and an intermediary product in the formation of the end product urea. The acceptance of this theory rested on the comparison of proteid metabolism in mammals with that in birds and reptiles, and on the apparent parallelism between the excretion of uric acid and urea. In 1887 Mares[1] studied the hourly excretion of uric acid and urea after rich proteid meals, and found that the uric acid excretion reaches its maximum and returns to a permanent level four or five hours before the urea reaches its maximum. Evidence has gradually accumulated to show that uric acid is an intermediary product of a group of proteids which form only a small part of the total proteid material of the organism, a group consisting of the nucleins and their decomposition products, the xanthin or purin bases. Soon after Mares had demonstrated the lack of coincidence in the hourly excretion of uric acid and urea, Hirschfeld[2] found that on a diet which did not include meat, but substituted for it varying quantities of other proteid foods, no parallelism occurred in the daily excretion of uric acid and urea, but that the uric acid remained practically constant, while the urea underwent marked fluctuations, corresponding to the variations in the quantities of proteid food. Horbaczewski[3] in 1891 fed nuclein made from spleen pulp, and obtained a marked rise in uric acid elimination. This observation was followed by numerous experiments in which various organs rich in nuclear materials, such as the thymus, the liver, pancreas, spleen and the kidney, were shown similarly to increase the uric acid elimination. Lüthje[4] and Minkowski[5] made the same observation in dogs, and Brandenburg[6] obtained an increase in uric acid after enemata of thymus.

---

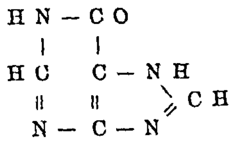
* A lecture delivered before the post-graduate students in medicine at the Johns Hopkins Medical School.

[1] Mares: Arch. slav. de biolog., 3, p. 207, 1887.

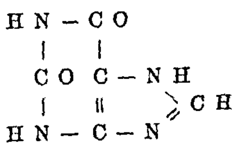
As Kossel had pointed out, nucleins yield, as decomposition products, the xanthin or, as Fischer has called them, the purin bases. The nucleins are substances which occur in cell nuclei, and consist of albumin combined with a nucleic acid. Nucleic acid contains in its molecule some one of the purin bases, and on decomposition splits up into this base and a phosphorus-containing portion. The purin bases, combined in the molecule of nucleic acid, are termed combined or bound purin bases; those which are uncombined are termed free. The bases which have so far been found combined in the nucleins are hypoxanthin, xanthin, guanin and adenin. These are closely related, chemically, to uric acid, together with which they are, according to Fischer, substitution products of a hypothetical substance which he termed purin, having this formula:



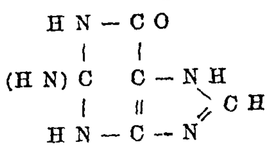
Hypoxanthin is 6. oxypurin.



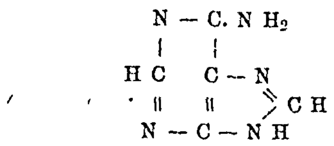
Xanthin is 2.6 dioxypurin:



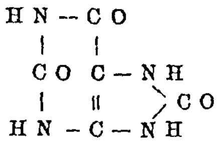
Guanin is 2. amino 6. oxypurin:



Adenin is 6. oxypurin:



While uric acid is 2.6.8 trioxypurin:



Hypoxanthin and xanthin, as may be seen, are oxypurins, while guanin and adenin are aminopurins.

Horbaczewski[7] had shown in 1888 that spleen pulp, which is rich in leucocytes, if allowed to undergo decomposition in the presence of oxygen, formed uric acid; if oxygen was excluded, it formed purin bases. This fact, and the close chemical relationship of uric acid to the purin bases, led a number of investigators to study the effect of the purin bases on the uric acid excretion. Strauss,[8] and later Jerome,[9] obtained a marked increase in uric acid excretion on adding beef extract to the diet, and Minkowski[5] gave hypoxanthin with the same marked result. The ability of the nucleins and purin bases to increase the uric acid output in the urine, therefore, appeared to be well demonstrated.

The converse side of the problem had, however, not been neglected. It had been noted by Mares, as well as by later investigators, that when the nucleins and purin bases were excluded from the body by starvation, the uric acid excretion was reduced much below the usual amount, but by no means disappeared. The same result was obtained by omitting from the diet meats of all kinds, soups, broths and all other substances containing nucleins and purin bases. On such a diet the uric acid became much less in quantity than on a mixed diet, just as was found during starvation, and after reaching a level remained constant from day to day, quite independently of changes in the amount of proteid in the food.

It seemed just to conclude from this that some constant source of production of uric acid exists in the body. In view of the relation between the feeding of foods rich in cellular elements and the consequent increase in the amount of uric acid in the urine, it seemed fair to assume that the continued excretion of uric acid, on a nuclein-free diet, was to be explained by the breaking down of cells and cell nuclei of the organism itself. The uric acid arising in this manner from the metabolism of the body tissues has been termed endogenous uric acid; that due to nucleins and purin bases introduced with the food, exogenous uric acid.

Based on the facts thus outlined, recent investigations, particularly those of Burian and Schur,[10] have determined more accurately the conditions which influence the normal excretion of uric acid from these two sources, and which will perhaps serve to form the starting point from which the pathologic physiology of uric acid metabolism may be rationally worked out. The essential fact, perhaps, on which our present conceptions of uric acid metabolism rests is the fixed value which, in a given individual following a given mode of life, the endogenous uric acid maintains. This uniformity is shown by the results of several observers who estimated at different periods during a number of months or years the amount of endogenous uric acid in the same individual. Thus Burian and Schur, at three different times in the course of eighteen months, found the endogenous uric acid in one individual to be 0.57 g., 0.60 g., and 0.60 g. Sivén[11] in his own case found 0.43 g. and 0.47 g. two months apart, and Kaufmann and Mohr[12] 0.558 g. and 0.525 g. six weeks apart.

[10] Burian und Schur: Pflüger's Arch., 80 and 87.

As the figures quoted will suggest, the amount of endogenous uric acid is not the same for all individuals, but within limits varies with the individual and in a given individual with the amount of cell-destruction that is going on in the body, that is, with the amount of exertion to which he is subjected. Burian and Schur, by keeping individuals on a diet of milk, eggs and bread, or on a vegetable diet, have determined the endogenous uric acid in three cases, which excreted in twenty-four hours 0.54 g., 0.30 g., and 0.39 g., respectively. Kaufmann and Mohr found in four cases to which exactly the same diet was given 0.54 g., 0.31 g., 0.44 g., and 0.36 g. As referred to above, Sivén in his own case found 0.43 g. of endogenous uric acid; Krüger and Schmid[13] found 0.45 g., Mendel, Underhill and White[14] in two individuals found 0.35 g. endogenous uric acid excreted, Taylor[15] found 0.28 g., and Walker Hall[16] 0.48 g. The extremes in the daily amounts of endogenous uric acid in normal individuals are 0.2 g. and 0.7 g. According to Walker Hall this individual variation runs parallel to the body weight. In all of these determinations, the mode of life, the amount of work done by the individual, was kept constant, so that the maintenance of a uniform excretion of uric acid must be assumed to depend on this condition. In the way of direct proof Sivén has shown that more uric acid is excreted hourly during the hours of work than during the hours of sleep, and also that continuous rest in bed probably diminishes the amount of uric acid compared to that excreted during an active life. No observations have been made in regard to the amount of uric acid excreted during excessive muscular work.

When nucleins and purin bases have been eliminated from the diet variations in the amount of nitrogen metabolism have practically no effect on the uric acid excretion, nor is the condition of nitrogen equilibrium essential. Burian and Schur have shown that with an individual in nitrogen equilibrium excreting 16 g. of nitrogen per day, the uric acid varied between 0.58 g. and 0.54 g. When the nitrogen level was reduced to 9 g. per day, the uric acid remained almost exactly the same, varying between 0.54 g. and 0.56 g. On the other hand, Sivén also obtained a uniform excretion of endogenous uric acid in spite of a total failure to establish nitrogen equilibrium, and in spite of marked fluctuations in the amount of nitrogen taken into the body. In addition to these observations, it is also probable that variations in the number of calories contained in the diet produce no change in the endogenous uric acid, though some observers are inclined to think that an excessive number of calories tend to lower the amount of uric acid.

The quantity of endogenous uric acid eliminated in the urine is, therefore, peculiar to the individual, and varies with the amount of cell change going on in the organism, but is entirely independent of the general nitrogen metabolism and of the non-nitrogenous constituents of the food—in other words, provided the organism is normal, the endogenous uric acid is uninfluenced by the general metabolism.

The exogenous uric acid is an additional quantity of uric acid arising from the nucleins and purin bases introduced with the food. Accurate feeding has shown that the proportion of nucleins and purin bases excreted as uric acid represents a fixed percentage of the amount of purin bases, bound or free, taken in the food. On adding a definite quantity of hypoxanthin to an otherwise purin-free diet, Burian and Schur found that in man about 50 per cent. of the nitrogen contained in the hypoxanthin appeared in the urine as uric acid. Others have come to the same result, although there is some variation in the exact figures—Krüger and Schmid, for instance, recovering as much as 63 per cent. of hypoxanthin-N as uric acid-N. Of xanthin-N introduced, Burian and Schur found 43 per cent. to appear as uric acid-N. Guanin and adenin, on the other hand, when added to a purin-free diet, apparently cause no increase in the uric acid. Though Krüger and Schmid recently recovered 40 per cent. of adenin-N as uric acid-N, their result is open to question because of their method. Of these four purin bases, therefore, hypoxanthin and xanthin, which are oxypurins, increase the uric acid excretion, while guanin and adenin, which are aminopurins, fail to do so; that is, the free oxypurins may be oxidized to uric acid, while the oxidation of the free aminopurins results in other decomposition products.

If, however, these four purin bases be ingested by the organism as bound purin bases, combined in the nuclein molecule, the oxidation of guanin and adenin seems to follow other lines than when they are ingested as free bases. As bound bases both guanin and adenin also increase the uric acid elimination in certain definite proportions. Calves' liver, which contains bound hypoxanthin, causes an increase in the amount of uric acid-N equal to 50 per cent. of its contained hypoxanthin-N. Thus 500 g. of liver, which contain 0.6 g. purin-N (almost entirely hypoxanthin-N), cause an increase in uric acid-N of 0.31 g., equal to 52 per cent. of the hypoxanthin-N; 400 g. of spleen, containing 0.64 g. hypoxanthin-N, increase the uric acid-N by 0.33 g., also about 52 per cent. Of guanin, which is combined in the nuclein of the pancreas, about 50 per cent. is excreted as uric acid; Weiss[17] substituted 200 g. of pancreas for 200 g. of lean meat, making an increase of 0.146 g. in purin-N due entirely to bound guanin-N, and produced an increase of 0.072 g. in uric acid-N, equal to 49 per cent. of the additional guanin-N. Adenin is combined in the nuclein of the thymus, and so ingested causes an increase in uric acid which, however, is equivalent to only 25 per cent. of the total amount ingested. Burian and Schur on two successive days gave 620 g. of thymus, containing 2.48 g. of adenin-N, and recovered 0.6 g. as uric acid-N, or 26 per cent. Weiss recovered 22 per cent.

The aminopurins which can thus increase the uric acid output when combined in the nuclein molecules form an intermediate group between the oxypurins which, both bound and free, are oxidized to uric acid, and the methylated purin bases which are never converted to uric acid. The last, such as caffein (1.3.7. trimethyl-xanthin). and theobromin (3.7. dimethyl-xanthin) apparently cause no increase in the uric acid, but appear in the urine partly as such and partly as other purin bases. Though this has been the almost unanimous finding, Taylor has obtained a perfectly definite and unquestionable increase in the uric acid after the addition of coffee to a mixed diet, which was kept constant.

Uric acid, therefore, has two sources: First, the breaking down of cell nuclei of the body itself, which for each individual, under normal conditions, remains approximately constant, and, secondly, the nucleins and purin bases of the food which may vary greatly and produce corresponding variations in the uric acid output. The uric acid arising from the first source (the endogenous) varies normally, with the individual, between 0.2 g. and 0.7 g. in twenty-four hours. The uric acid arising from the second source (the exogenous) has been found to bear quantitative relations to certain of the purin bases introduced with the food, and to be entirely uninfluenced by others.

The question as to where in the body the purin bases undergo decomposition or oxidation has been approached in several ways, and has been best studied in dogs. Spitzer[18] has added hypoxanthin and xanthin to aqueous extracts of dog's liver and spleen, and found that in passing a stream of air through the mixture these bases were oxidized to uric acid. Guanin and adenin could also be oxidized in the same way, but to a much smaller extent. In dogs in which anastomosis had been made between the portal vein and the inferior vena cava, Hahn and Nencki[19] found the excreted *uric acid greatly increased above the output before the operation.* Beside the liver and spleen, other tissues, as the thymus and the voluntary muscles, are capable of oxidizing the purin bases to uric acid. While the liver is perhaps the chief tissue in which this decomposition takes place, the fact that it is not the only one is further demonstrated by the subsequent course of Hahn and Nencki's dogs, in which the uric acid excretion after remaining unusually high for a variable period, returned to normal. Here other tissues replaced the liver in disposing of the purin bases.

The decomposition of the purin bases is, however, carried beyond the stage represented by uric acid, and is effected by practically the same tissues and organs as the oxidation to uric acid, among which the liver is again the most important. Stokvis[20] many years ago showed that uric acid is destroyed by extracts of dog's liver. Chassevant and Richet[21] more recently isolated from such extracts an enzyme-like substance which decomposed uric acid, and Jacoby[22] found that by boiling the power to effect this decomposition was greatly diminished, thus strengthening the proof of its enzyme-like character. Ascoli[23] approached the subject in another way. He transfused isolated livers with defibrinated blood containing a known quantity of uric acid, and found a marked diminution in uric acid after the passage of the blood through the liver. In still another way Burian and Schur *have demonstrated that the dog's liver is a very important point of destruction of uric acid.* They isolated the liver and the kidneys from the circulation by ligating the aorta above the celiac axis, *and found that whereas no uric acid could be demonstrated in the blood before this interference, a weighable quantity could be separated a few hours after the operation. With this well-proven activity of the liver in the dog, it is striking and a matter of importance that the kidneys are entirely inactive.*

*The herbivora form a striking contrast to dogs and other carnivora in the distribution of the tissues in which purin metabolism takes place.* The oxidation of the purin bases takes place in the liver, spleen, thymus and other tissues. *On the other hand, it has been found* that extracts of beef liver *could not* decompose uric acid at all and that the liver in all herbivora acts only slightly. The kidneys, however, and in beef the muscles as well, decompose uric acid very rapidly. Thus, though the liver and some other tissues in the herbivora are able to oxidize the purin bases to uric acid, they can not carry the oxidation beyond this point, while the liver in carnivora can effect the complete oxidation. In man this accurate study has not been made.

The end product of the metabolism of purin bases, as far as man is concerned, is still a matter of doubt. For carnivora it has been shown by Salkowski,[24] and later by Mendel and Brown,[25] that uric acid was excreted largely as allantoin, while Minkowski[5] after feeding hypoxanthin to dogs recovered an amount of allantoin almost equivalent to the hypoxanthin which was not excreted as uric acid. Similar results have followed thymus feeding. In rabbits, on the other hand, uric acid introduced into the organism is partially excreted as glycocol. As this is decomposed to urea by the liver, it is possible that the portion of glycocol not excreted is so oxidized, and that urea forms at least *one of the end products of uric acid decomposition.*

*It is, therefore, unquestionable that certain tissues in the mammalian organism can oxidize purin bases to uric acid,* and that sometimes the same, sometimes other tissues, continue the oxidation of uric acid.

So far, only the fate of the exogenous purin bases has been considered. It has also been demonstrated, however, that the endogenous purin bodies, those arising from the metabolism of the organism itself, are similarly oxidized, and that the endogenous uric acid of the urine represents only the unoxidized portion of these. Burian and Schur have brought positive proof of this for the dog, and made it extremely probable for man. The blood of normal dogs contains no recognizable quantity of uric acid. Removal of both kidneys does not at all increase it. Only when the liver *is at the same time isolated from the general circulation, that is, when the most important uric-acid-destroying organ is removed,* does a measurable amount of uric acid appear. This occurs both when dogs have been kept on a purin free diet, and when they have been fed meat. Therefore, both the endogenous and the exogenous uric acid can be completely oxidized by the tissues when elimination is precluded by removal of both kidneys, and both accumulate in the blood when the uric-acid-destroying tissues are removed. Therefore, within the body as well as in isolated organs, uric acid represents only a *stage in* purin metabolism, and is not necessarily an end product. That a certain proportion of uric acid *escapes* oxidation, and is always contained in the *blood,* is obvious from the fact that when the means *of its de-*

struction are removed it begins to accumulate in the blood. The uric acid which is found in the urine represents that portion of the uric acid in the blood which has been taken up and excreted by the kidneys. When a purin-free diet is given, the uric acid excreted, therefore, represents only a certain portion of the uric acid, which is formed by the breaking down of all nuclei, and enters the circulation. In dogs only about 4 per cent. of the uric acid injected subcutaneously is also eliminated to the extent of 4 per cent. If exogenous uric acid is excreted to this extent, and endogenous uric acid, as has been shown, exists in the blood, and, while the liver remains intact, may be destroyed just as is exogenous uric acid, there is no reason for doubting that it, too, is eliminated in the same proportion—that is, to the extent of 4 per cent.

When uric acid is injected subcutaneously in man, 50 per cent. is eliminated in the urine. This is the same proportion in which the hypoxanthin-N is eliminated. It may, therefore, be said that hypoxanthin is wholly oxidized to uric acid, and that of this one-half is eliminated as such. This means that a much larger proportion of uric acid reaches the kidneys in man than in dogs. Whether, in man, uric acid be increased in the blood when the means of elimination and decomposition are excluded from the circulation, can not be determined experimentally. From the identical behavior of the exogenous uric acid in dog and man, it is fair to assume that the endogenous uric acid in man is oxidized just as the exogenous uric acid and that the endogenous uric acid found in the urine is about one-half the entire amount found in the body. This, then, affords a criterion by which can be determined the ability of the body to take care of the purin bodies introduced into it or arising in it. If the exogenous and endogenous uric acid be controlled by the same conditions, as presumably they are, the degree to which the body can eliminate as uric acid ingested purin bases will at the same time indicate the extent to which the body can oxidize the uric acid arising within itself. This, therefore, forms a new method for the study of uric acid elimination in disease.

Uric acid, however, forms only a part, though under normal conditions by far the largest part, of the purin bodies eliminated in the urine, and should always be considered in its relation to the total quantity of purin substances in the urine. As has already been pointed out, certain of the purin bodies, the methylated purin bases, caffein, theobromin and others, do not ordinarily affect the uric acid excretion. They do, on the other hand, markedly increase the purin bases in the urine. It has been claimed by various writers that in certain diseases some of the exogenous and endogenous purin bodies are eliminated as purin bases at the expense of the uric acid, that is, that the latter forms a smaller proportion of the total purin bodies of the urine. Minkowski,[26] considering nucleic acid as a loose chemical combination consisting of adenin, guanin and nucleotin-phosphoric acid, suggests that "the end products of the metabolism of the purin bases may vary according to the organ in which the decomposition of the molecule of nucleic acid takes place, and the method by it occurs." By way of an hypothetical example, he adds that "by oxidation hypoxanthin may possibly arise directly from nucleic acid, and be easily oxidized; that by simple hydrolysis, on the other hand, only adenin is set free, the oxidation products of which retain the amido ($NH_2$) group instead of oxygen, and for this reason may have other effects on the organism." The effects on the organism of many of the purin bases has received very little attention. Walker Hall, however, has recently demonstrated that injections of hypoxanthin into rabbits, equal, weight for weight, to the quantity of purin bases usually ingested by man, cause degenerative changes in the cells of the liver and the kidney and produce changes in the intima of the smaller blood vessels.

In the light of the recent changes in the views concerning the physiology of uric acid, much of the work previously done on the elimination of uric acid in disease requires revision. Only the most recent observations have that accuracy which has been made possible by our better knowledge of the endogenous uric acid and of the quantitative relations between the excretion of exogenous uric acid and the amount of purin bodies introduced with the food. Of the latter point practically no application has as yet been made.

The study of endogenous uric acid in disease has not been carried far enough to warrant general conclusions. Inasmuch as the endogenous uric acid arises from the breaking down of cell nuclei, and, therefore, from nuclear nucleins, its relation to the phosphoric acid elimination has attracted some attention, the elimination of the two being parallel under normal conditions and in some diseases as well, notably in gout. The increase in all pathologic conditions in which an increased amount of tissue metabolism occurs has long been recognized. In all fevers, in diseases such as pneumonia, in which a cellular exudate is constantly thrown out and reabsorbed, in the primary anemias, in pernicious anemia in which blood destruction is constantly going on, and in leukemia in which a great number of leucocytes disintegrate, in the cachexias, and in other conditions—this increased waste results in an increase in the nucleins in the circulation to be broken down, and a consequent increase in the uric acid and purin bases eliminated. Uric acid may, therefore, be regarded as an index of the amount of cell destruction, of the amount of nuclear metabolic change, which is going on in the body.

The factors which control the deposition of uric acid salts in the tissues, as in gout—the retention of uric acid—have not been determined. It will be interesting to learn in what proportion the gouty individual eliminates as uric acid or purin bases known quantities of ingested purin substances. From a consideration of the phosphoric acid and nitrogen balances in gouty individuals between the attacks, Kaufmann and Mohr have obtained results which tend to show that the gouty individual has periods of retention and of elimination of phosphoric acid and nitrogen, which do not occur in normal individuals taking exactly the same diet (see also Futcher[27]). In the interval between attacks the endogenous uric acid, in the cases in which it has been determined, has been quite within normal limits. Whether the retention of uric acid which occurs just before and in the early part of the acute gouty attack represents a disturbance of purin metabolism only, or is part of a general metabolic disturbance, is still a matter of doubt. Woods-Hutchinson[28] has recently brought forward arguments which tend strongly to show that gout is a direct intoxication, entirely independent of uric acid, the variations in which, as well as its deposition in the tissues, are secondary.

[27] Futcher: The Journal A. M. A., p. 216, 1897.

[28] Woods-Hutchinson: Lancet, Jan. 31, 1903.

In nephritis, except when uremia develops, the uric acid excretion is probably more nearly normal than that of urea; that is, uric acid is probably more easily eliminated.

To summarize our present knowledge of the conditions which control the elimination of uric acid: The source of uric acid in mammals lies in the nucleins and their decomposition products, the purin bases. The uric acid eliminated in the urine arises partly from the nucleins and purin bases due to the breaking down of cell nuclei in the body itself, that is, the endogenous uric acid; and partly from the nucleins and purin bases contained in the food, the exogenous uric acid. The amount of endogenous uric acid excreted in twenty-four hours is the minimum which the individual normally excretes; it does not change in quantity, though it varies with individuals; it is influenced only by the mode of life, but in no way by the quantity or character of the constituents of food which do not belong to the group of nucleins and purin bases. The exogenous uric acid is always an addition to the endogenous uric acid, and depends in amount entirely on the quantity of certain purin bases contained in the food. Of the free purin bases only the oxypurins, hypoxanthin and xanthin, increase the uric acid elimination; of the bound bases both oxypurins and aminopurins increase the uric acid; the methylated purin bases do not effect the uric acid elimination, but increase the purin bases in the urine. Of the oxypurins, both bound and free, one-half is excreted in man as uric acid; of the bound aminopurins some appear one-half, some one-fourth as uric acid. The fraction is in each case independent of the individual, and is practically constant.

Uric acid is not an end product of metabolism, but is intermediary between the purin bases and some lower oxidation product which has lost the purin characteristics. This product may possibly be urea, but this is certainly unproven in man and only probably in lower animals. In the carnivora allantoin, in the herbivora glycocol, forms a large portion of the recoverable (recognizable?) oxidation products of uric acid.

What the relations of uric acid to gout may be has only begun to be worked out, but it is evident that it has very little to do with many of the pathologic conditions for which it has been unduly held accountable, and for which it can at best be regarded only as an index.

# TUBERCULAR JOINTS AND THEIR TREATMENT.*

DAVID C. PEYTON, M.D.
JEFFERSONVILLE, IND.

The frequency of tubercular disease of the joints, and the necessity for early diagnosis, serve as an excuse for this paper on a subject about which so much has been written. The writer desires to emphasize the fact that the present article is intended only as a résumé of some of the more important well-proven and accepted conditions which make it an imperative *duty* of both the general practitioner and surgeon to be able to recognize a tubercular joint in its incipiency, for on our ability to diagnose this trouble early depends the success of treatment. We must recognize that joint tuberculosis is at first a local manifestation. We must disabuse our minds of the idea that it originates only in the children of tuberculous parents, and of the idea that all joint pain is rheumatic.

Tuberculosis in the region of a joint is essentially of the bone, although it may have originated in the synovial membrane. It is a disease of bacillary infection, which may occur from without or through the blood vessels. If the joint structure is in a healthy condition, the effect of the lodgement of these micro-organisms is *nil*. But, on the other hand, given some slight injury, or a cell weakness, the natural defensive power is weakened, the point of attack is fortified and we have the beginning of a disease process which, if not very early diagnosed *and treated in the most radical way*, finally results in abscess, necrosis, ankylosis, loss of limb or loss of life.

The irritation caused by the tubercle bacilli often excites inflammatory processes, and if staphylococcus infection is added suppuration ensues and the nodule may finally be gotten rid of; but suppuration is not to be regarded as an essential of a tubercular process. The action of bacilli is necessarily destructive, but by their presence phagocytosis immediately becomes active.

Tuberculosis of the joints may occur at any age, and is very frequent in children. The inflammation may begin either in the synovial membrane or the ossifying tissue of the head of the bone.

In the realm of causes we have lack of food and sunshine, foul air, etc., or the action of any process serving to lower the natural cell resistance of the part, and we have the onset of the disease. The general symptoms are rigidity, swelling, pain, flexion and disturbed relation as to length. After a very slight injury the child begins to limp, and remember this one symptom can never be regarded as a habit in a child, for it limps only from cause. A muscular atrophy takes place above and below some of the joints, making very prominent any hypertrophy that may exist. The pain is often characteristic, for it occurs in severe attacks at the instant the patient falls asleep, due, of course, to the momentary muscular relaxation and consequent approximation of the two ends of the inflamed bone. This, of course, is a symptom of a rather advanced state, but often we have a reflected pain, in knee, hip, abdomen, or chest, with altered contour of the body in various positions, the pain often at first only slight, possibly only a slight uneasiness or restlessness at night. This with the various other manifestations should serve as a warning signal to arrest our attention and cause us to make a most thorough investigation of the condition before us.

Flexion is also often an important symptom, and is associated with muscular rigidity, which is one of the earliest and most persistent symptoms of joint disease.

The writer is not unmindful of the difficulty sometimes encountered in a differential diagnosis of tubercular arthritis from the several other inflammatory diseases involving the joints. But it does seem that by a most careful analysis of the cases presenting to us distinct joint lesions we should be able in most cases to make a differential diagnosis.

The tendency of tubercular arthritis is toward destruction of the joint, with subsequent attempts at ankylosis of the two surfaces, either by bony or fibrous tissue, and frequently in a bad position. The patient, however, who is thus left to an uncertain nature, may die of a long-continued suppuration, the result of a mixed tuberculous infection before this process is completed.

---

* Read before the Mississippi Valley Medical Association.

We have in the tuberculin test a most certain agent in rendering a diagnosis possible. You are all no doubt familiar with its use for diagnostic purposes, so that I shall only treat of the most salient points to be observed in its use. The patient's temperature line and other conditions should be most carefully noted for two or three days prior to the injection, when the patient should again be carefully observed and a careful comparison of the temperature curve made. If we have a deposit anywhere, we get the tuberculin reaction—chill, fever, etc. If no reaction follows the injection within forty-eight or sixty hours, and we have reason to suspect the presence of the tubercular disease, then we are warranted in a second injection. The most perfect asepticity is to be observed.

The writer is aware of the dangers to be encountered from its employment, but does not consider them nearly so great as the evil consequences of a so-called expectant or do-nothing plan of treatment as a result of the uncertainty of early diagnosis in these cases. Of course, the dangers should be carefully considered and compared with the expected benefits to be derived by reason of a certainty in diagnosis before resorting to its use.

In coming to the question of treatment of this very prevalent disease it is the purpose of the writer to advocate a most radical plan, which should be adopted just so soon as a diagnosis has been made. He believes that the great majority of the varied and many kinds of expectant and waiting plans of treatment are unscientific, and not founded on facts. This statement is borne out by statistics which show a most unsatisfactory state of results. It may be safe to rely on rest, fixation of joint, fresh air, etc., for the first ten days or two weeks, provided an early diagnosis has been made. It is a mistake to delay active interference for weeks, depending on an already weakened and incapacitated nature to arrest the disease process, and our error is usually repaid by the formation of pus, bone necrosis, ankylosis, loss of limb, or possibly loss of life. If we but return for a moment to the pathology of this condition we must be impressed with the error of these older and generally accepted plans of treatment.

The surgical treatment of tubercular joints presents for our consideration the following operative procedures, according to the state of advancement of the joint involvement: Arthrotomy, arthrectomy, excision or resection, and amputation.

By the early and free opening of the affected joint, thus insuring free drainage, and thoroughly irrigating it with a hot normal saline solution, the writer has gotten some eminently satisfactory results. The irrigation should be repeated daily for a week or ten days, or even longer, according to the degree of involvement. Even where the process has gone to suppuration or beginning necrosis we may expect the most marked benefits from this plan of treatment, which is especially to be commended in all patients under 18 years of age, for by the more radical operations we may destroy the epiphyses, with consequent arrest of development or growth. However, in the advanced state of the disease, whether in the adult or the child, the more radical operations are not only advisable, but are imperatively demanded to save usefulness of limb, or at least limb if possible, and sometimes life. Where necroses with fistulæ have formed, their removal by arthrectomy or excision is to be insisted on. It is especially in the smaller joints that the most satisfactory results are obtained by arthrotomy and arthrectomy.

To recapitulate, the importance of an early diagnosis can not be overestimated. The early adaption of some of the radical means of treatment for this disease in its incipiency with eminently satisfactory results, seems to the writer to be founded on scientific reasons, especially so when we are brought face to face with the facts that a postponement of their application means that a little later on we are forced to adopt them when these same conditions have reached an advanced state of destruction, and that, too, with less satisfactory results. Finally, no surgeon not imbued with the fullest sense of his duty looking to the most perfect technic should attempt these radical operations.

# DIPHTHERIA OF THE NOSE.

W. SCHEPPEGRELL, A.M., M.D.
NEW ORLEANS.

Diphtheria of the nose will be here considered as a primary disease, and distinguished from the more common variety in which the diphtheritic inflammation of the nasal passages is secondary to diphtheria of the throat, or even from that form which is sometimes found in epidemics, in which the diphtheritic process originates in the mucous membrane of the nose, but soon appears in its usual form in the throat.

In its characteristics, diphtheria of the nose differs widely from diphtheria of the throat. The constitutional disturbances are frequently so mild that they attract little attention on the part of the patient, and in the majority of cases, the physician is appealed to only on account of the continued obstruction of the nostrils or the attending epistaxes. Renal and neurotic disturbances are rare, and paralysis of the velum palati, so frequently found in ordinary diphtheria, is not referred to in the literature on the subject. The absence of these complications is worthy of remark, on account of the greater absorbing capacity of the nasal mucosa as compared with that of the throat. We are all familiar, for instance, with the rapidity with which cocain is absorbed in the nostril and the greater tendency to constitutional disturbances than when this alkaloid is used in the throat.

In primary diphtheria of the nose, as in diphtheria of the throat, a fibrous exudate forms on the mucous membrane. This pseudomembrane may be removed, but the attempt is usually followed by bleeding and the membrane reforms. The constitutional disturbances are not marked, and resemble the first stage of an ordinary coryza. The main annoyance to the patient is the interference with nasal respiration and the discharge from the nose. Epistaxis is not uncommon, and frequently is the first symptom that attracts the attention of the patient or of the parents to the unusual character of the nasal affection.

As in diphtheria of the throat, the bacilli are located in the mucous membrane and do not spread through the system. The constitutional disturbance, when present, is due either to the local irritation, the absorption of toxins, or the effects of the interrupted or impeded nasal respiration.

The discovery of the Klebs-Loeffler bacillus has been of invaluable assistance in demonstrating that diphtheritic rhinitis is the same morbid process as diphtheria of the throat. Every case, in which a pseudomembrane is found in the nasal passages and which is not due to the application of the electrocautery or acids, should be examined for the Klebs-Loeffler bacillus.

In primary diphtheria of the nose, the early symptoms, as already stated, resemble to some extent those of an acute coryza, for which they are frequently mistaken. There is the usual elevation of the temperature, headache and general discomfort. In the first stages, the mucous membrane of the nostrils is congested as in a coryza, followed by, first, a watery and afterwards a mucopurulent discharge. A tendency to epistaxis develops later, being due to partial loosening of the pseudomembrane, the hemorrhages sometimes occurring several times a day.

This stage of nasal diphtheria is rarely seen by the physician, owing to its being mistaken for an ordinary "cold." When fully developed, a rhinoscopic examination shows the mucous membrane swollen and covered with a thick pseudomembrane, white or light gray in color, and which may be limited to a portion of one nostril or may cover the entire surface of both nasal cavities. In the early stages, one nostril only is involved, but later both show the results of the diphtheritic inflammation. If both nostrils are affected, the nasal respiration is much obstructed, and may even be entirely interrupted.

In mild cases, the healing process begins to assert itself by the second week, but may be prolonged to a much greater length, and sometimes as long as two months. In ordinary cases, there may be afterward found no result of the diphtheritic inflammation, but in aggravated cases, in which there has been loss of substance, this is followed by cicatricial tissue, and sometimes by synechia, which may interfere greatly with normal nasal respiration. Such aggravated cases are very rarely found in primary nasal diphtheria, the cases reported being complications of diphtheria of the throat, and then only in severe epidemics.

Primary diphtheria of the nose is so unusual an affection and ordinarily so mild in its character, that the ordinary methods of isolation are not always easy to enforce in the families where it appears. This also applies to the question of reporting such a case as an infectious disease to the board of health. I recall a case in which I had diagnosed diphtheria of the nose, and accordingly sent a culture to the state bacteriologist for examination. A positive report of the presence of the Klebs-Loeffler bacillus was sent me, the board of health at the same time, in accordance with the law, posting on the residence of the patient the white flag, indicating the presence of diphtheria. The father soon afterward called at my office in great excitement and objected strenuously to the flagging of the house. On my refusal to request the board of health to remove the flag, he showed me a certificate from his family physician certifying that he had examined the child and found it to be affected only with "simple catarrh." I am unable to state the subsequent history of this case, but it illustrates the effect of the rarity and mild effects of the disease, not only with the laity, but even with some members of the medical profession.

In making a bacteriologic examination of the nostrils in such cases, one negative result is not decisive. The duration of the disease is usually several weeks, and if the first result is negative, other cultures should be made before concluding definitely that the pseudomembranous process in the nose is not of a diphtheritic character. As an illustration of this, Concetti[1] reports a case in which the first bacteriologic examination was negative, but two weeks later the culture developed large colonies of the Klebs-Loeffler bacillus.

The prognosis in the ordinary form of nasal diphtheria is good, the cases usually making a good recovery. In the gangrenous form reported by some authors, however, the prognosis is very grave, and where septic disturbances have developed, it may be hopeless. Fortunately the latter cases are of extreme rarity.

My treatment of diphtheria of the nose consists simply in syringing the affected nostrils with a 25 per cent. solution of peroxid of hydrogen, this being followed by a free douching with the normal saline solution. Bichlorid and carbolic solution, recommended by some authors, should be avoided on account of the danger of the solution entering the stomach.

The question of the use of the diphtheria antitoxin in such cases is one on which I would invite an expression of opinion from the members of this Section. As already stated, the disease is usually so mild in its development, and sets up so little constitutional disturbances, that, from the standpoint of therapy only, it does not seem to be indicated as in the usual forms of diphtheria.

As to the influence of the antitoxin on the duration of the disease, I am not prepared to make a statement, although the point is an important one. While it is by no means as infectious as diphtheria of the throat, still the fact that the Klebs-Loeffler bacillus is found, indicates possibilities of infection, and therefore a remedy which would shorten the duration of the disease without involving any special danger, should naturally be recommended. In regard to infection, however, I find but little stated in the literature on this subject, and, in the cases which have come under my observation, no second case has developed in the families in which I have been called on to treat the disease. This can not be due to the antiseptic character of the treatment, as in the majority of cases which I have seen, the diphtheritic rhinitis had existed for a number of days, thus giving ample opportunity for infection had there been any special tendency to it. Owing to the presence of Klebs-Loeffler bacillus, however, I always insisted on the same isolation as in the usual form of diphtheria.

**Resistance of Bacteria to Pressure.**—Chlopin and Tammann, in the *Zeitschrift f. Hygiene u. Inf.-Kr.*, xlv, No. 2, 1903, report from Dorpat tests of the resistance of bacteria to pressure up to 13,000 kilograms per square centimeter, equivalent to 2,900 atmospheres. None of the bacteria was killed by this pressure, and one application produced scarcely any impression on them. But six repetitions of compression had an evident inhibiting action. Pneumonia and cholera germs are much less resistant than those of pseudo-diphtheria and anthrax, while yeasts are like the last, extremely resistant.

**Intestinal Origin of Tuberculosis.**—The *Klinisches Jahrbuch*, ii, No. 4, 1903, contains the report of extensive experimental and clinical experience bearing on the question of the intestinal origin of tuberculosis. The author, Nebelthau, states that in his material at Halle direct transmission of the tuberculosis from other persons was evident in all the cases in children. His experiments on animals showed that the tubercle bacilli were able to penetrate the intact intestinal wall, and induce lesions beyond, with no trace of their presence in the intestines. He found goats much more susceptible than dogs, and believes that children rank with goats in this respect. He advocates prophylactic measures to prevent transmission of both human and bovine tuberculosis by way of the respiratory apparatus and the digestive tract.

# ACUTE, SUBACUTE AND CHRONIC INFECTIOUS OSTEOMYELITIS;

## ITS PATHOLOGY AND TREATMENT[*]

EDWARD H. NICHOLS, M.D.
Demonstrator of Surgical Pathology at the Harvard Medical School; Assistant Visiting Surgeon to the Boston City Hospital.
(From the Surgical Laboratory of the Harvard Medical School. For the Division of Surgery, Harvard University.)
BOSTON

### INTRODUCTION.

The object of this paper is to state the sequence of the changes which occur in the bones in infectious osteomyelitis; to emphasize the difference in the pathologic conditions which exist during the acute, subacute and chronic stages of the disease; and especially to suggest certain operations which are indicated by the pathologic conditions that exist during the different stages, and which generally are not appreciated. These operations, properly carried out, offer a very certain cure for conditions which, if allowed to persist, cause recurrent attacks of local infection or produce chronic and frequently incurable destruction of bone with permanent disability.

The statements made here are based almost entirely on personal work carried on for the past eight years. The work has included examination of pathologic material obtained from operations or necropsies on cases occurring at the Boston City Hospital and the Children's Hospital, experimental work at Harvard Medical School, and clinical cases, most of which were seen during my own tour of duty at the Boston City Hospital. A few other clinical cases have been furnished by the great kindness of my colleagues on the hospital staff, who have allowed me to see the patients and present the records of the cases.

### DEFINITION.

Infectious osteomyelitis is an acute suppurative inflammation of the bone, and is always due to infection of the bone marrow by pyogenic microörganisms. The process is essentially like the process seen in a furuncle, and has been graphically called "bone furunculosis," although the process in bone is somewhat modified by the peculiar anatomy of the tissue. In bone the process begins in the marrow of the alveolar spaces, which communicate freely with each other, but are enclosed by a dense shell of cortical bone. Hence the process, at first circumscribed, may quickly involve the entire marrow of an infected bone, because the products of bacterial infection are retained within a shell of dense bone, and the primary focus can be reached only by an extensive bone operation.

### CAUSE.

The direct cause of acute infectious osteomyelitis is always an infection by some pyogenic bacterium. The organism which most frequently is the cause is the *Staphylococcus pyogenes aureus*, e. g., Lannelongue[1] and Achard[2] found that of 130 cases of osteomyelitis 103 cases gave a pure culture of that organism. In some thirty primary cases of my own all but four were due to the same organism. The staphylococcus produces, as a rule, the most typical and extensive bony destruction. Sometimes the *Staphylococcus albus* or *citreus* is present in pure cultures, and Lexer[3] says that the character of the lesions is the same as that of those produced by the aureus, and the lesions can not be distinguished clinically. The bone lesions frequently are secondary to suppurative lesions elsewhere in the body, e. g., furuncle or carbuncle, and the organisms are carried to the bones by the blood.

In a few cases the infectious organism is the *Streptococcus pyogenes*. In some cases the lesions produced by the streptococcus are like those produced by the staphylococcus and can not be distinguished clinically, but these cases are rare.[3] As a rule, the streptococcus has a tendency to affect the joints, to cause separation of an epiphysis, or to attack the superficial portion of the bone and cause a periostitis rather than a diffuse osteomyelitis. Such bone infections frequently occur in infants from mothers with septicemia, and may be due to infection during delivery. Or they may be secondary to phlegmon or erysipelas. Osteomyelitis produced in young animals by inoculation with streptococcus does not differ from that produced by the staphylococcus.

In still other cases[4] Fränkel's pneumococcus causes osteomyelitis. The appearance and distribution of the lesions vary, but on the whole the tendency is the same as in the case of the streptococcus, i. e., to a superficial or joint infection. These cases may occur secondary to pneumonia, pleurisy, or empyema, or the point of primary infection may be hidden.

---

[4] Fischer and Levy: Bacteriolog. Befund bei Osteomyelitis und Periostitis, Deutsch. Zeitschr. f. Chir., 1893.

Not infrequently the typhoid bacillus may cause suppurative areas in bone, and Keen[5] has collected thirty-eight such cases, in fourteen of which the bacillus was present in pure cultures. As a rule, such lesions are of small extent and superficial and the destruction of the marrow is slight unless a secondary infection with some pyogenic organism occurs. The cases generally occur quite late in the course of typhoid fever.

As a rule, the infecting organism is present in pure culture, but sometimes a mixed infection occurs, and such cases are said to be especially severe. In cases of chronic osteomyelitis with open sinuses and exposed bone a great variety of organisms, pathogenic and saprophytic, may be present. In one such case with a very foul-smelling discharge, I found the *Bacillus fetidus*. Secondary infections with the colon bacillus, the pyocyaneus and anthrax have been reported.

Therefore, infectious osteomyelitis is not a specific disease, but is an acute inflammation of bone that may be produced by any one of a variety of pathogenic organisms, or by a mixed infection. Any[3] pyogenic organism which can be carried in the blood stream may be deposited in the bone and produce suppuration. Some show great tendency to such an action, others but little; some settle by preference in the bone marrow, others at the periphery in the periosteum or in the joints; some tend to act at the point of greatest bone activity, others at points of injury.

*Experimental Proof.*—This has been proved by experiments on animals by many observers. Characteristic osteomyelitis has been produced in the bones of animals by injection of pyogenic organisms into the nutrient arteries of the bones, or by direct injection of organisms into bone marrow, or by fracturing bones and inoculating animals subcutaneously. For such inoculation experiments the *Staphylococcus pyogenes aureus*,[6] the *Streptococcus pyogenes*, the pneumococcus and the typhoid bacillus have been used. Ackermann[7] has produced it by injecting large numbers of the colon bacilli. Ullman produced "sterile abscesses" in bone by injecting an emulsion of calomel directly into the marrow. The gross and microscopic appearance of the experimental lesions was the same, no matter what the cause.

### PREDISPOSING CAUSES.

Certain general causes favor the occurrence of osteomyelitis. The disease usually occurs in individuals whose bones have not attained complete development, i. e., in children or adolescents, although it is not rare in adults, and sometimes occurs in advanced life, as shown in a case reported by Bottomley.[8] About one-half of the cases occur between the ages of thirteen and seventeen, although young children often are infected. The disease is said to occur in boys about three times as often as in girls. The disease frequently appears after extreme fatigue, or exposure to cold or wet. One of the cases mentioned later came on within a few days after bathing in cold water in early spring. Injuries of moderate severity, e. g., contusions of bones, frequently precede the disease by so short a time as to suggest a possible cause, although there may have been no break in the skin. A preceding attack of some infectious disease is often noted, e. g., measles, scarlet fever, pneumonia, or frequently typhoid fever. Osteomyelitis which follows infectious diseases usually is due to a secondary infection by some pyogenic organism, e. g., staphylococcus, although both the pneumococcus and the typhoid bacillus may be the direct cause of the bone lesion. The frequent occurrence of osteomyelitis subsequent to the exanthemata probably is due to lowered resistance to bacterial infection as a result of the infectious disease, as well as to the septicemia frequently present in those diseases. Mallory has shown that in smallpox[9] and typhoid fever[10] areas of necrosis are frequently present in the bone marrow, and such areas, secondarily infected by pyogenic organisms, may well be the starting points of acute suppuration of the marrow.

Compound fractures frequently become infected by pyogenic organisms, and the bone undergoes osteomyelitic changes. In former days such infections frequently were fatal. Under modern methods the infection when it occurs generally is slight, and, since the pus usually can readily escape through the wound in the soft tissues, the results are seldom fatal, although the destruction of bone by the infection may be sufficient to greatly delay healing, and to lead to the formation of small sequestra and enduring sinuses. Sometimes the same result follows infection of bone stumps after amputations.

### METHOD OF INFECTION.

The infection of the bone often is secondary to a local infection in some other part of the body, e. g., furuncle, paronychia or chronic ulcer, and the organism carried from such a focus by the blood produces infection of the bone marrow. In some cases the organism enters the body through the respiratory tract, as when an osteomyelitis produced by the pneumococcus occurs subsequent to a pneumonia, pleurisy or empyema. Infection may occur through the intestinal tract, as when osteomyelitis is produced by the typhoid bacillus, although other types of intestinal infection are said to be rare. Ullman[6] fractured the bones of animals and then fed them with infected food, but failed to produce infection of the bone. Frequently the osteomyelitic focus appears to be the only point of infection and it may be quite impossible to detect the primary point of entrance of the infective organism.

### LOCATION.

Osteomyelitis nearly always begins in the diaphysis of the long bones, usually near the epiphyseal line. This is in sharp contrast with tuberculosis of bone, which, in the large bones at least, practically always begins in the epiphysis. Rarely, however, osteomyelitis is said to begin in the epiphysis, and so to simulate acute tubercular disease. It is my belief that such cases usually begin in the diaphysis, perforate the epiphyseal line very early, and then extend to the joint. The femur and the tibia are the bones most frequently attacked; then the humerus, but no bone is exempt, and short long bones, e. g., the phalanges or flat bones, may be affected. Usually only one bone is diseased, but sometimes several bones are affected. After one bone is diseased other bones may become involved after an interval of days or weeks. Multiple osteomyelitic lesions are, however, not common.

### PATHOLOGIC PROCESS.

The primary area of infection is always, apparently, in the bone marrow. The bony trabeculæ and the cortex are destroyed only secondarily, and their destruction and solution is usually slight in the early stages, although in the later stages the destruction may be very extensive. The process almost always begins in the diaphysis of the long bones, frequently near the epiphyseal line. Rarely, however, the process is said to begin in the epiphysis, and then may extend into the adjacent joint early. After the organisms gain access to the marrow cells they multiply and produce a soluble toxin which causes necrosis of the adjacent marrow cells. Since the cortex is relatively impermeable while the marrow spaces allow free communication and extension of the infection, necrosis of a very considerable portion of the marrow of a long bone may take place before marked purulent infiltration occurs. In such a case the marrow may appear gelatinous and injected to the naked eye, while under the microscope the marrow cells everywhere are necrotic, and among them are numerous colonies of the infecting organism. As a rule, purulent exudation of polynuclear leucocytes with extensive solution of marrow cells appears early. Then the bone is, on being sawed open, mottled with numerous yellow or greenish areas of suppuration, together with reddened areas of injection or hemorrhage. Solution of the soft tissue of the marrow is usually great. Sometimes even in the early stages there is some solution of bony trabeculæ, with the formation in the spongy bone of cavities containing serum, necrotic cells and leucocytes. Hence "bone abscesses" appear, but these usually are small. The infection may very rapidly extend along the entire marrow canal of a long bone. The extension, however, is always more or less irregular, apparently because of the irregular communication between adjacent alveolar spaces, due to the irregular arrangement of the bony trabeculæ, so that the bone nearly always shows a mottled red and yellow appearance from the presence of necrotic and injected and purulent areas, while small areas of relatively unaltered marrow may persist in close proximity to the altered areas.

The infection usually extends quite early through the dense cortical bone, probably along the haversian canals, and produces an inflammatory exudation and suppuration between the periosteum and the outer layer of cortical bone, i. e., a subperiosteal abscess, and may strip the periosteum from the bone over a great extent or completely. The infection may also extend to adjacent soft tissues, and cause myositis, or a subcutaneous inflammation, or an abscess. Such an abscess may be very extensive, and has direct communication with the marrow of the bone, although the point of communication may not be detected readily. Finally such an abscess may extend to the surface and break through the skin at one or more points, although such an event rarely occurs spontaneously in severe cases, since fatal toxemia and septicemia frequently occur before spontaneous evacuation. If such a spontaneous evacuation does occur, sinuses leading down to dead bone may persist indefinitely.

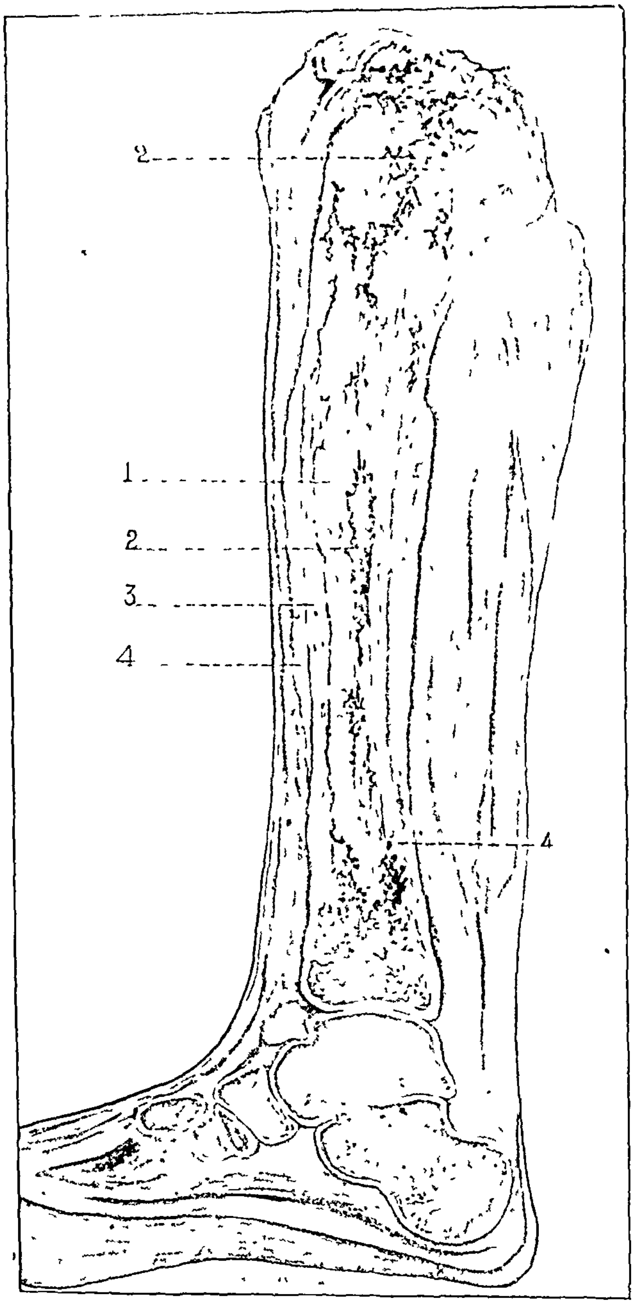

Figure 1.—Vertical antero posterior section through the leg and foot of a case of infectious osteomyelitis Duration about seven weeks 1. Areas of suppuration 2. Areas of injection and granulation tissue. 3 Necrotic cortical bone. 4. Newly formed periosteal bone, but still plastic This is the best stage for the operation Upper epiphysis invaded by suppuration Below process checked by epiphyseal line.

As a rule, the infection is checked and confined to the diaphysis by the epiphyseal line. In some cases, however, especially in older children or adults in whom the epiphyseal line is partly or completely ossified, the infection extends through the epiphyseal line, involves the epiphysis, and then may extend to the joint and produce a purulent inflammation of the synovial cavity and more or less complete destruction of the joint. Or there may be a destruction of the epiphyseal line and a separation of shaft and epiphysis—"spontaneous fracture."

The cortical bone usually becomes necrotic over considerable areas. The extent to which cortical necrosis occurs depends partly on the extent of the destruction of the endosteum and partly on the amount of separation of the periosteum from the shaft. If the periosteum is stripped from the cortical bone for any great extent, necrosis of at least the outer layer of the underlying cortical bone is likely to occur. On the other hand, if much of the endosteum which lines the shaft and covers the trabeculæ is destroyed by the inflammation, a corresponding necrosis of the inner layers of the cortex or of the trabeculæ will occur.

If the periosteum is separated from the cortical bone about its entire circumference, as frequently happens in these cases, necrosis of the entire circumference of the cortex, at least in its superficial layers, may occur. If, internally, the entire circumference of the endosteum is destroyed, the entire inner circumference of the cortex may become necrotic, at least in its inner layers. If periosteum and endosteum both are affected at any given level, a complete necrosis of the shell of cortical bone may occur. Since the amount of destruction of the endosteum and the extent of the stripping of the periosteum vary greatly in individual cases, the extent of necrosis of the cortical shell also varies within very wide limits. Sometimes the entire shaft of cortical bone may be destroyed relatively early in the disease. In other cases only a long sliver of the outer layer of the cortex may become necrotic, and ultimately be separated as a sequestrum, without opening into the marrow cavity.

In nearly all cases, because of the impermeability of the cortical bone and the consequent rapid extension of the suppuration over a large extent of marrow, the area of suppuration from which absorption takes place is large, the difficulties in the way of spontaneous or artificial evacuation are great, while symptoms of toxemia and septicemia appear early and are extreme.

Cortex of femur.

### REPAIR.

If from spontaneous evacuation of the abscesses, or from operation, a fatal result is avoided, the infectious process may become limited and the process of repair may begin. The reparative process produces peculiar and important gross pathologic conditions, due to the peculiar anatomic conditions found in bone. In general, repair within the shaft is brought about by the formation both of granulation tissue which arises from the reticulum of the marrow, and of new bone which arises from the endosteum. As a rule, a portion of the infected marrow and cortex becomes necrotic over a greater or less extent and persists, for a time at least, as a bony "sequestrum." Outside of the shaft the periosteum becomes more or less separated from the underlying necrotic shaft, proliferates, and produces a shell of new bone, which surrounds the necrotic original shaft with a shell of new bone,, i. e., forms an "involucrum." An understanding of each of these steps demands an accurate consideration of the process of repair of normal bone, as studied in experimental lesions in animals.

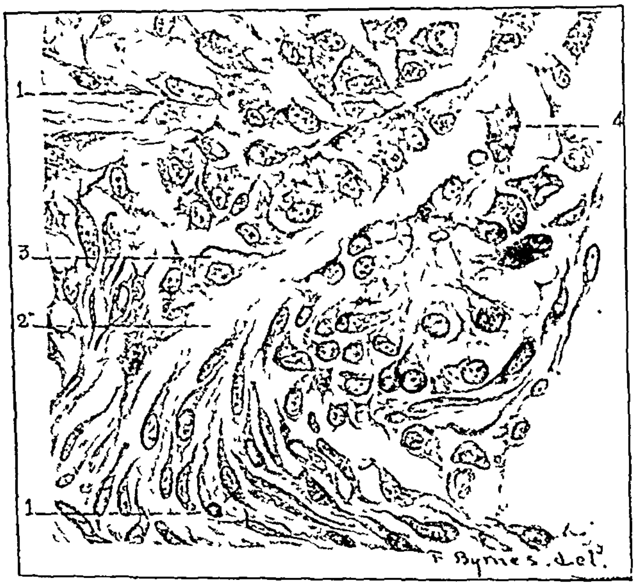

Figure 3.—High power of cells derived from endosteum showing formation of early osteoid trabeculæ. 1, 1. Epithelioid cells, with fibrillar intercellular material. 2. Intercellular material becoming homogeneous, previous to deposit of lime salts, "osteoid" trabecula. 3. Epithelioid cell on surface of osteoid trabecula, "osteoclast." 4. Epithelioid cell retained in osteoid trabecula, to become "bone corpuscle."

### REPAIR OF UNINFECTED EXPERIMENTAL FRACTURES.

The process can best be studied in bones in which a loss of bony tissue is produced without dislocation of the fragments, e. g., by drilling a small hole vertically into the bone. In this way the process of repair can be studied without the complications which arise in complete fractures.

In such fractures hemorrhage occurs, followed in a few hours by an inflammatory exudate. By the second day reparative proliferation occurs. The proliferation occurs within and outside of the cortex of the bone. The external proliferation arises from the periosteum, and consists of a mass of epithelioid cells, which soon become spindle-shaped and are accompanied by young blood vessels derived from adjacent blood vessels. This mass of cells forms the early "external callus." The internal proliferation arises partly from the layer of cells lining the inner surface of the cortex (endosteum) and partly from the connective tissue reticulum of the marrow, and forms a mass of cells in the shaft similar to those produced by the periosteum. This mass of cells forms the early "internal callus." By the fourth day a homogeneous intercellular substance appears between some of the cells of the internal callus, the early "osteoid" tissue. Fusion of adjacent areas of such osteoid tissue forms the early outline of new trabeculæ in the internal callus. Some of the proliferated cells are included in the osteoid areas, and are converted into the bone corpuscles of the osteoid trabeculæ, while others of the cells assume a polygonal shape, persist at the periphery of the trabeculæ and take on the function of depositing bone, i. e., become "osteoblasts." The cells which carry on these functions apparently are derived from the cells which arise from the endosteal cells, although in the early stages they can not be distinguished morphologically from the fibroblastic cells derived from the connective tissue reticulum of the marrow. Ultimately there comes a deposit of lime salts in the osteoid trabeculæ of the internal callus, and so the bony trabeculæ are formed. Besides the proliferation of endosteal cells there is a proliferation of the connective tissue of the marrow reticulum, and fibroblastic cells, which ultimately forms a scar within the cortex, are produced. New blood vessels arise from preëxisting blood vessels.

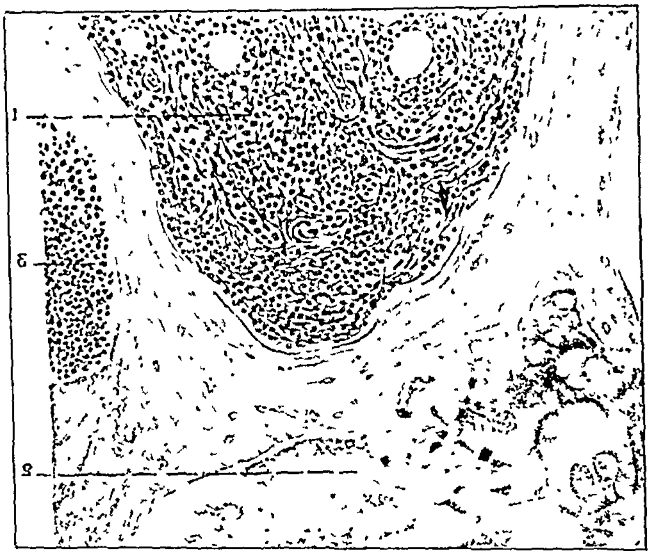

Figure 4.—Adjacent alveolar spaces in marrow of osteomyelitis of tibia, duration about ten days. 1. Alveolus filled with granulation tissue. 2. Alveolus filled with serum and entirely necrotic cells, among which are numerous colonies of staphylococci. 3. Alveolus filled almost entirely with polynuclear leucocytes.

A formation of bony trabeculæ in the external periosteal callus takes place in an exactly similar way.

The cortical bone in experimental fractures seems to have very limited or no power of proliferation, and the space in the cortical bone at first is filled with hemorrhage and exudation only, until the external and internal calluses project in from either side, meet, and fuse. After the fusion, new trabeculæ appear in the gap in the cortical bone. These are at first entirely free from the cortical bone, but finally become fused with the calcified portion of the cortex and thus form the "intermediate callus."

At first the newly-formed osteoid or osseous tissue is very vascular and formative osteoblasts are numerous. Later the blood vessels are much less numerous, the cellular elements are fewer, and the trabeculæ become laminated and have the same appearance as in normal bone.

### REPAIR IN OSTEOMYELITIS.

The general process in the repair of osteomyelitic bone is the same, but some of the special steps are modified by the degree, extent and character of the destructive process and by the persistence of the sequestrum. The steps will be described as they occur in the marrow, the cortex and the periosteum. It should be borne in mind that the endosteum covers all of the calcified trabeculæ as well as the inner cortical wall.

*Marrow.*—As has been mentioned, adjacent marrow spaces in the early stages may be normal, or show slight necrosis with little leucocytosis, or may be entirely necrotic, or the cells may be dissolved and the space filled with purulent exudation. Consequently the amount of proliferation in adjacent spaces after repair begins may vary a great deal.

The connective tissue of the reticulum of the fat marrow may proliferate to a great degree, and surround purulent areas with a more or less complete zone of granulation tissue, or in some cases may entirely fill up the marrow spaces at a given level, and so form a band of at first granulation, later dense scar tissue, thus separating the necrotic and infiltrated portion of the shaft from the sound portion. In a case of spontaneous osteomyelitis the scar tissue is likely to be irregularly distributed throughout the shaft surrounding the infiltrated areas. In compound fractures especially a definite transverse zone of granulation or scar tissue often separates the infected portion from the sound shaft. At first the granulation tissue may be edematous and show infiltration with lymphoid and plasma cells and numerous leucocytes. Later it becomes dense scar tissue. If a definite abscess has formed, it may be completely surrounded by a zone of scar tissue.

Beside the proliferation of connective tissue from the reticulum there may be a proliferation of the endosteum both from the inner wall of cortical bone and from the endosteum covering any of the trabeculæ. This may lead to a deposit of bone on the inner wall of the cortex, and to a thickening of the bony structure of the old trabeculæ, or to the formation of new trabeculæ. If such endosteal proliferation takes place it leads to a thickening of old bony structures and a formation of new ones which may surround infiltrated or necrotic areas with a wall of bone of increased density, or form a barrier of bone between necrotic and sound portions of the shaft; or, if the abscess is a local one, may entirely surround such an abscess, or may lead to an obliteration of the marrow canal at a given point.

Since the extension of the destructive process is very irregular, the distribution of the granulation tissue and endosteal bone may be correspondingly irregular, and may be diffusely scattered throughout the bone, may cause bony or fibrous encapsulation of diseased areas, or may divide diseased areas from sound portions of the shaft.

*Cortex.*—As has been said in discussing the repair of experimental fractures, dense cortical bone has very little or no power of direct repair. Repair of any considerable amount of necrosis of cortical bone depends entirely on the integrity of the endosteum within, and the integrity and adhesion of the periosteum to the outside of the cortical bone. If the endosteum is intact, the inner layer of the cortical bone may retain its vitality. In some cases in which the periosteum is entirely stripped from the underlying cortex, the cortex at the time of

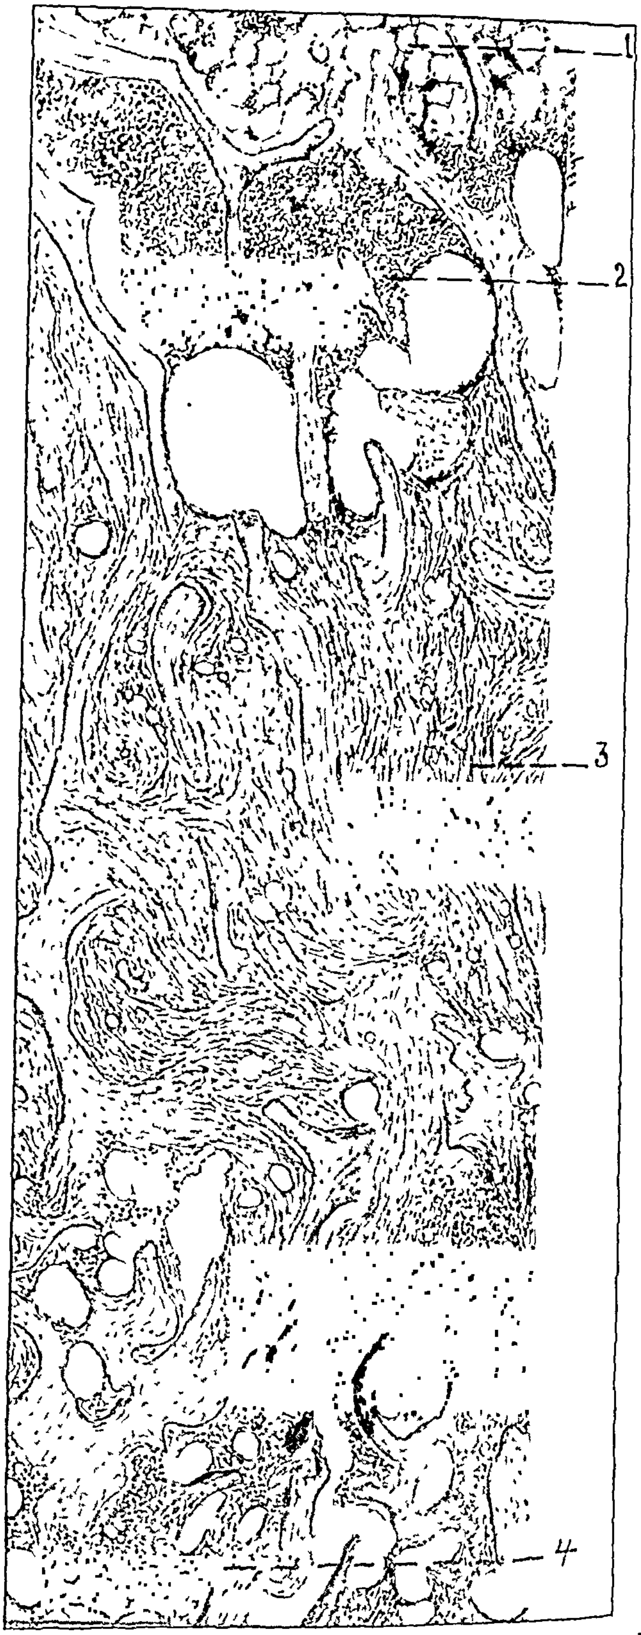

Figure 5.—Vertical section through an osteomyelitic compound fracture. 1. Alveolar spaces filled with necrotic cells and serum, with many colonies of staphylococci 2. Zone of polynuclear leucocytes in alveolar spaces. 3. Zone of scar tissue filling alveoli and separating infected bone from (4) normal red marrow and granulation tissue in alveoli.

operation may appear white, non-vascular and necrotic; but if the pus is entirely removed, it is certain that to a considerable extent the periosteum returns to its normal position, becomes adherent to the apparently necrotic cortex and maintains or renews its vitality. This adhesion of periosteum may be complete over the entire shaft, or more commonly takes place over only a part of the shaft, and fails to take place in other portions. This partly explains the occasional very irregular distribution of the necrosis of the cortical bone as seen in some sequestra.

The necrosis and inability to repair of the cortical bone is the chief cause of the persistence of sequestra and sinuses as seen in chronic osteomyelitis. The marrow has considerable power of repair, but the cortex, if necrotic, persists as a sequestrum, and either remains indefinitely, or is discharged piecemeal, or must be removed by operation; and in either case, leaves a cavity which has usually no power of closing itself.

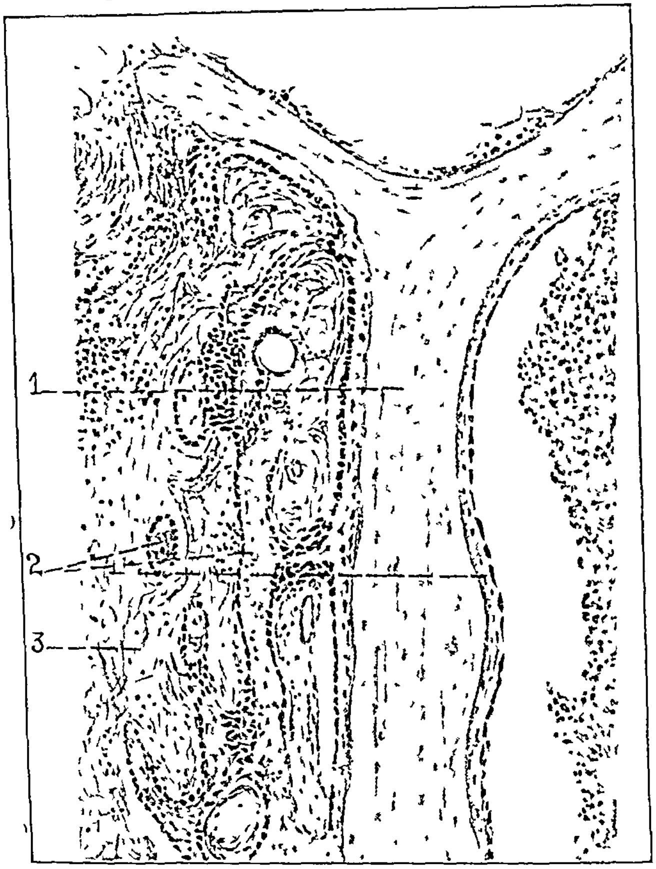

Figure 6.—Endosteal formation of bone arising from trabeculæ of marrow. 1. Original trabecula. 2. Newly-formed endosteal bone, partly adherent to original trabecula, partly appearing as new trabeculæ. 3. Alveolar spaces with granulation tissue arisen chiefly from reticulum of marrow.

*Periosteum.*—As soon as the pus has been evacuated and the inflammatory process has subsided the periosteum proliferates and endeavors to maintain the vitality of the outer layer of cortical bone, or produces new bone to replace that destroyed by the inflammation. As already mentioned, in some cases to a considerable extent the periosteum, after the pus is evacuated, again comes in contact with and adheres to the cortical bone, and the cortical bone beneath such adhesions retains its vitality. This explains the adherence of the periosteum in places to an extensive sequestrum, which throughout most of its extent is completely separated from the periosteum.

In most cases, if the periosteum has been stripped to a great extent, this adhesion between periosteum and cortex does not take place. But the periosteum undergoes a process of proliferation analogous to that seen in the formation of the external callus in fractures. The cells of the periosteum next to the necrotic cortex are polygonal and are the bone-forming cells. Between adjacent cells a homogeneous intercellular substance appears, early "osteoid" tissue, and by fusion of such intercellular material the outlines of early osteoid trabeculæ are formed. Some of the polygonal cells are enclosed in the osteoid tissue, become branched and take on the function of bone corpuscles for the new trabeculæ of osteoid tissue. Other cells remain in contact with the outer surface of the new trabeculæ and take on the function of bone deposition on the outer surface of the trabeculæ, i. e., become "osteoblasts." In this way the deep layer of the periosteum becomes converted into a thin layer of delicate new periosteal bone, usually separated from the necrotic cortical bone sequestrum. The further development of bone in the periosteum takes place peripherally, the deep layer of the membrane forming bone, the intermediate layer producing polygonal, bone formative, periosteal cells, while the peripheral layer consists of layers of spindle cells, such as are seen in normal periosteum.

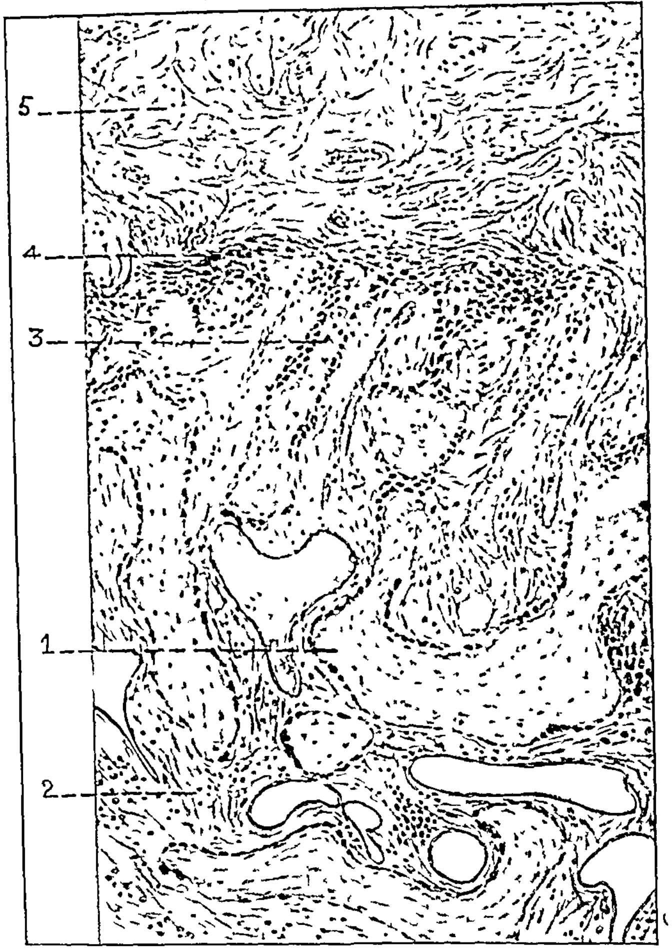

Figure 7.—Section through cortex and adherent new periosteal bone in osteomyelitis, duration about seven weeks. 1. Cortical bone trabeculæ. 2. Marrow spaces filled with granulation tissue. 3. Newly formed periosteal bone trabeculæ. 4. Osteogenetic layer of periosteum. 5. Fibrous layer of periosteum.

In the early stages the spaces between the newly-formed trabeculæ are filled with a rather myxomatous mass of cells, usually somewhat polygonal or stellate, with very delicate intercellular fibrillæ, usually very edematous. Among these cells lymphoid and plasma cells are very numerous, and occasional leucocytes are seen. Young blood vessels are numerous.

As the periosteum continues its peripheral growth with the formation of new periosteal bone, the old necrotic shaft finally becomes surrounded by a shell of newly formed periosteal bone, which, as a rule, is perforated at one or several points by sinuses for the discharge of pus from the necrotic shaft, i. e., an "involucrum" surrounding a "sequestrum" is formed. The sequestrum may lie entirely free, or, as already mentioned, may be adherent to the inner layer of periosteal bone to a greater or less extent. If there is a free space between sequestrum and involucrum the inner layer of the involucrum is lined by a layer of edematous granulation tissue from which a discharge of pus may continue indefinitely.

At first the periosteal bone is soft, partly osseous and partly osteoid, and very vascular, with myxomatous tissue in the alveolar spaces. The process of periosteal bone formation does not continue indefinitely, but continues only until sufficient new bone is formed to carry on the function of weight-bearing, i. e., at first the total diameter of new bone is greater than the diameter of the necrotic shaft was. This increase in diameter over that of the normal shaft is apparently due to the fact that the new bone is softer than normal bone, and consequently more of it is required to support a given weight than would be needed if the bone were normal. Later, as the new bone becomes denser and more like normal bone, there is a definite decrease in size of the periosteal shell, so that the total diameter of the shell may closely or exactly approximate the diameter of the original shaft.

In time the trabeculæ of the involucrum become completely ossified and osteoblasts become flattened out and approximated to the trabeculæ as an endosteum, just as in normal trabeculæ; the myxomatous granulation tissue becomes converted into fat marrow; and the entire involucrum assumes a structure like that of normal dense cortical bone or in some cases like the spongy bone of the epiphysis. Such dense bone has, just as cortical bone has, a very limited power of repair. Hence if at this late stage the sequestrum is removed, it leaves a cavity with walls composed of dense bone like cortical bone, which has very limited or no power of repair. This explains why cavities which are left after the removal of sequestra so often persist indefinitely and fail to close. This is especially the case if, at the same time the periosteal shell is forming, the marrow canal is closed by a plug of dense marrow bone, which arises by endosteal bone formation, or by a band of scar tissue which is converted by metaplasia into dense bone.

### GROSS APPEARANCE.

*Marrow.*—The gross appearances of osteomyelitic bone vary with the histologic conditions already described. In the acute stage, marrow is first affected. If examined very early, no suppuration may be seen. The marrow simply is infected and necrotic. At that time it appears injected and gelatinous. At that stage, during an operation, it may be impossible on account of the hemorrhage to be certain that any gross change is present. Usually, however, cases are not seen until suppuration is well marked. Then on opening the marrow a profuse discharge of pus takes place. This pus may be yellow, or greenish, or red from hemorrhage, or brownish from disintegrated blood pigment. Usually the pus contains many large or small oil drops from disintegrated fat marrow. This oily pus is very characteristic. At this time if the bone can be removed and sawed through vertically, the marrow presents, not a diffuse suppuration, but a mottled appearance, partly red from injected or hemorrhagic marrow, partly red or yellow from unaltered marrow, and partly yellow or greenish from suppuration. The distribution of the different areas is very irregular, and probably is determined partly by the distribution of blood vessels and partly by the facility or difficulty of extension from one alveolar space to another.

At a still later stage the appearance of the marrow is still different. The yellow areas of suppuration persist, while other portions are red and injected, but the red color at this period is due to the formation of granulation tissue in many of the alveolar spaces. In some cases, one end of the shaft may present this mottled appearance, while the other end may appear normal, while between the two there may be a pink or red band of granulation tissue entirely closing the marrow canal and separating the infected from the normal area. If the destruction of the infected marrow has been complete and the cortical bone also has become entirely necrotic, the shaft may be converted into a more or less complete bony tube, filled with dirty granular detritus and pus, and, if the bone is spongy, the necrotic trabeculæ form a mesh or frame work of brownish sponge-like structure.

*Cortex.*—The appearance of the cortex also varies with the stage of the disease. If examined very early, the periosteum is thick and edematous, injected, and is easily stripped from the bone. The bone itself looks white and shining, and often shows minute red vascular points. At a somewhat later stage the periosteum may be entirely separated from the bone by a collection of pus, oftentimes over the greater portion of the shaft. The periosteum may appear as a very considerable fusiform, fluctuating swelling or sac, often of large diameter. On incising such a sac, the bone is seen smooth, white and often dull. In the stage when necrosis of the cortical bone is complete, the cortex appears dirty white, or brownish, or black, bare, and absolutely without luster. It may be broken into spicules of varying size, or may be perforated by sinuses, or may be worm eaten. The cortex in the early stages may be partly adherent to the periosteum, even when necrosis is marked. In the later stage the necrotic shaft may lie perfectly free in the periosteal shell or in some cases portions of it may be perfectly free, while other portions of it are united to the thick bony periosteal shell or involucrum by bony adhesions, and separation of the two may be difficult. Or, if the suppurative process has lasted for years, as often happens, only a few thin worm-eaten spicules of cortical bone are seen, lying in a cavity of the periosteal shell which is covered with unhealthy granulations.

*Periosteum.*—The gross appearance of the periosteum in the early stages has been mentioned above in connection with the cortex, i. e., at first it is thickened and injected, and usually at an early stage is elevated from the bone by an extensive subperiosteal abscess. A few weeks later the periosteum is several times thicker than normal, and the deep layers are more or less rigid from the formation of bony trabeculæ, at first very delicate, pinkish white and crackling under the touch like hoarfrost. This crackling can also be detected by pushing a needle through the granulations at the edge of a sinus, when the new periosteal shell can be felt and heard to crackle under the touch of a needle. This can be used as a gross method to determine the proper time to operate (cf. infra). As time goes on, this periosteal layer increases in thickness, and finally forms a shell of variable thickness about the cortical sequestrum. The thickness of such a shell may be very great and equals, or sometimes exceeds, the total thickness of the original shaft.

This periosteal bone forms a cylindrical shell about the sequestrum and is always perforated at one or several points by sinuses for the discharge of pus. The shell, as already said, may be closely adherent to portions of the sequestrum, or may be separated entirely from the necrotic portion of the shaft, although it may be adherent by bony growth to the living shaft or to the epiphysis at the upper and lower ends of the sequestrum. If such unaltered portions of the shaft closely connected with the periosteal shell do exist, they usually are divided from the necrotic shaft by transverse bands of dense scar tissue, or more commonly in the old cases by a transverse layer or plug of very dense scar tissue or bone which frequently entirely occludes the marrow canal. In such a case the necrotic shaft lies in a cavity or box of dense ivory-like cortical bone. Such a cavity usually is lined with a layer of dirty unhealthy granulations. If the sequestrum is removed from such a cavity it leaves a cavity of dense bone lined with granulations, which has practically no tendency to heal. These cases are seen in old and long-continued "bone abscesses."

*Soft Tissues.*—Beside these changes in the bone, secondary changes in the soft tissues appear early. Even before perforation of the periosteum appears the adjacent muscles, subcutaneous tissues and skin show edema, redness and induration. If the periosteum is perforated an abscess, often very extensive, may appear in the soft tissues. Such an abscess may spontaneously perforate the skin at several points, forming permanent sinuses. The edges of such a sinus are lined with unhealthy granulations. Such sinuses may be very large. In long-continued cases the skin and subcutaneous tissue are thickened from formation of dense scar tissue, while edema and infection persist. In extreme cases an affected limb may for years be nearly twice normal size.

## SYMPTOMS.

The disease usually begins with sudden local pain, usually quickly becoming severe, and generally of a throbbing character. This pain is usually referred to the shaft of some one of the long bones, commonly at one end near the epiphyseal line. The limb at this time often is not so sensitive on motion, but the pain is intense on percussing the bone, even very lightly, or on continued pressure. Usually at a very early period swelling of the soft parts about the bone appears, and this swelling soon shows pitting on pressure and marked redness. The adjacent joint frequently becomes tender, hot and swollen. This swelling at first more often is due to the edema of inflammation rather than to direct infection, for cultures of the joint fluid at this time often are sterile. Rise of temperature to 103 or 104 often accompanies the early pain, and frequently the pulse is greatly accelerated, 120 to 140 beats per minute. Evidence of constitutional disturbance and infectious absorption usually appears early. The tongue is dry, coated and tremulous. the face drawn and flushed. Delirium, often of a mild type, is a very common factor, and this delirium frequently persists for some weeks after drainage of the bone has been made. Abscess of the soft parts may give deep or superficial fluctuation. Sinuses may appear. The leucocyte count usually is very high.

Such a chain of symptoms would appear to present a fairly distinct clinical picture, and it would be difficult to overlook such a typical case. The diagnosis of early cases, however, quite contrary to some statements, may be very difficult. Even in severe cases, the pain for some days is not severe. Sometimes the patients complain of very moderate pain for several days before local symptoms are evident, and the pain at first frequently is referred to an adjacent joint in which no gross change can be made out. Sometimes swelling of an adjacent joint comes on so early as to call entire attention to the joint, and distract one's observation from the bone focus until later swelling and edema of soft parts, or abscess over the bone, give evidence of extreme bony destruction. These cases frequently for days are treated as articular rheumatism.

The infection may be so severe and the patient's mental condition so stupid that the pain is not noticed, so that the cases may be mistaken for typhoid fever; this, too, by very competent and well-trained men.

These difficulties, however, do not excuse many of the frequent failures to recognize the condition, which seem often to be due to a neglect to remember that osteomyelitis is a not uncommon disease in children and young adults.

## DIAGNOSIS.

The diseases most frequently mistaken for osteomyelitis are early acute tuberculosis of joints, acute articular rheumatism, gonorrheal rheumatism and typhoid fever.

Tuberculosis of the joints practically always begins in the epiphysis of the long bones, while osteomyelitis almost always begins in the diaphysis. This distinction will clear up the diagnosis in many cases. It is said that occasionally osteomyelitis begins in the diaphysis, although I never have seen such a case. In such a case the very acute onset, the early extreme pain and the early appearance of constitutional symptoms should permit of a diagnosis. Moreover, in epiphyseal osteomyelitis, spontaneous separation of the epiphysis is said to be common.

If a portion of the shaft is left at the time of the resection and the sound end is cut off square at right angles to the shaft, the same triangular dead space may persist, but in such a case if the end of the old shaft is tapered off by chisel and forceps, the bone may be so pointed as to allow complete approximation of the periosteum. Such an expedient can not, however, be safely adopted with the epiphysis and yet allow the preservation of the epiphyseal line.

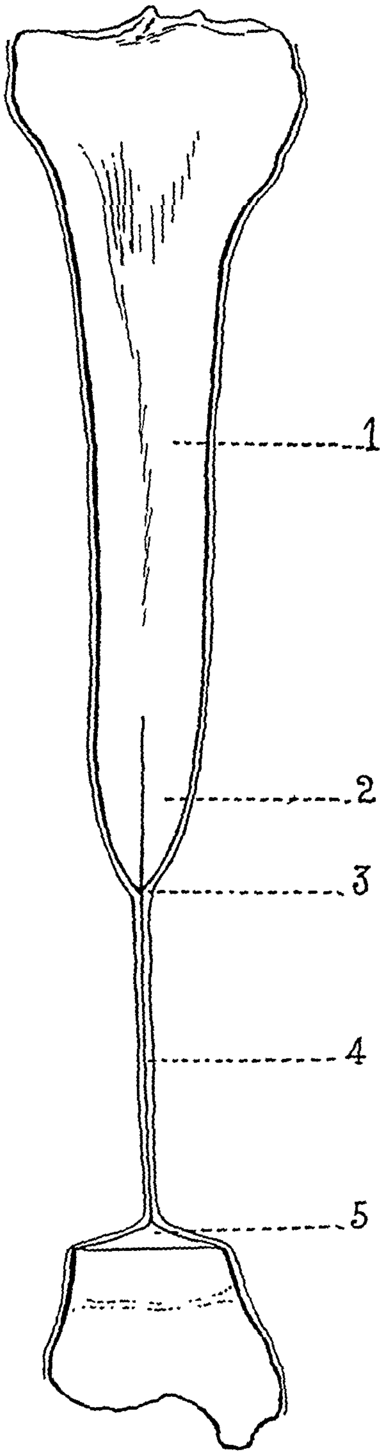

*Figure 9.—Diagram to illustrate method of avoiding dead space* in case of partial removal of e. g., shaft of tibia. 1. Upper portion of shaft of tibia. 2. Lower end of shaft chiseled into conical shape. 3. Close approximation of periosteum to conical end of shaft, obliterating upper dead space (See Fig. 8, No. 3). 4. Approximated periosteum, after removal of portion of shaft. 5. Dead space just about epiphysis, as epiphysis can not be made conical without interfering with epiphyseal line.

AFTER-TREATMENT.

Certain precautions and difficulties in the operation and after-treatment should be considered. Of course, some infection and suppuration will be present when the operation is done, but they should be minimized as far as possible. For this purpose free incisions, followed by careful daily dressing and irrigation, should be provided for some time before removal of the shaft when necessary. Often the reaction to the inflammatory process in the soft tissues and periosteum leads to the formation of an enormous amount of vascular granulation tissue in the soft parts about the bone. Incision of such parts may lead to a very great oozing hemorrhage during the operation, sufficient at times to make the operation dangerous from loss of blood. This may be avoided by the application of an Esmarch bandage before the operation and removal after the dressing. I have known of two cases where the hemorrhage was so severe as to require that the operation be done in two steps; at the first step periosteum was partly peeled back from the bone and the operation completed some days later after hemorrhage had ceased.

In regard to closing the wound, it is to be remembered that the operation practically never can be done on perfectly aseptic tissues. Some suppuration may take place between the approximated surfaces of periosteum, and some is sure to take place between the soft tissue edges. Consequently it is advisable to leave the stitches in the periosteum as far apart as is possible with accurate approximation of the edges. The edges of the soft tissue may be closely approximated, but provision for drainage should be made by very small gauze wicks or catgut drains.

The operation produces usually moderate depression, not so severe as an amputation. In spite of all precautions there is apt to be some evidence of septic absorption, coming usually on the second or third day, but usually disappearing within a week. In two cases the post-operative infection was sufficient to cause mild delirium for a week.

The wound may heal by first intention over the greater portion, but some redness and slight sloughing of the edges usually appear. In one case this sloughing was sufficient to cause considerable gaping both of soft tissue and periosteum. Sinuses often develop for a time, but have always ultimately disappeared. They usually appear near the epiphysis, or at the junction of periosteum and shaft. As has been said, sometimes a slight amount of curetting may be necessary before permanent closure takes place. It is desirable to prevent backing up of infection because of the danger of infection of the epiphysis and ultimate infection of the joint as happened in one case (Case 5, cf. infra).

The first dressing should be done usually by the third day; a wet dressing may be necessary for the first ten days. After that time, dressing should be done sufficiently often to absorb any discharge.

Marked induration along the line of the bone usually is felt by the third week. From that time on the bone gradually increases in density and size. The new shaft at first and for some months has no marrow canal, but is composed entirely of trabeculæ of periosteal bone with myxomatous granulation tissue, instead of fat marrow. The new shaft grows to be larger than the original shaft during the early months, but in time decreases in size and practically comes to the size of the corresponding shaft. In course of time a marrow canal appears in the new bone, to judge from the *x*-ray pictures. I never have had a chance to examine such bones at autopsy.

As a rule, the new shaft is a trifle more irregular than the original shaft. The shaft is strong enough to allow free use after from five to eight months. Even when the entire diaphysis has been removed, if the epiphyseal line has not been interfered with, no shortening of the limb need result, and that, too, in young adults of fourteen years. As far as function and use go, the results often are absolutely perfect. Even in cases where the epiphysis is interfered with, the shortening may be slight and the function perfect.

### OPERATIONS WHEN NO ACCESSORY SPLINT BONE IS PRESENT.

The above operation is particularly applicable to bones like the tibia and fibula, or the bones of the forearm. In cases where there is only one bone in a limb, e. g., the humerus, the danger of deformity from muscular contracture must be considerable if the necrotic shaft is removed before the periosteum is rigid. But, as has already been said, if the periosteal shell is allowed to become too rigid and dense, it has very little or no power of repair centrally. The triangular space, however, between epiphyseal line and approximated periosteum showed, in some of the operations on the tibia, some power of growth centrally, so it was believed that the periosteal shell, if the necrotic shaft were removed from the box of involucrum early enough, might have sufficient power of central growth to repair an extensive central defect. Naturally the time when such a power would be greatest would be when the shell was as young as possible, i. e., just as soon as the shell was sufficiently hard to bear weight or maintain the contour of the limb. This assumption has been found to be true. The difficulty of telling just when this time has arrived is considerable. The $x$-ray furnishes the best means of determination, and the relative apparent increase in the size of the shaft due to formation of involucrum tested by palpation also is of assistance. With sufficient fixation, new periosteal bone whose diameter is equal to one-half the diameter of normal shaft is sufficient.

### POINTS IN THE TECHNIC.

Hence in such cases the secondary operation must be undertaken at a somewhat later time than the secondary operation in cases where an accessory splint bone is present. In the two cases where there has been opportunity to try the operation, the time was judged to be sixteen weeks. The operation requires an incision through soft parts down to periosteal shell. Then with chisel and gouge a longitudinal opening must be made through the periosteal shell long enough to reach the lower end of the necrotic shaft, unless, from the early drainage operation, a gap has been left in the periosteum. If sufficient opening through the periosteum is made at the primary operation, but little will need to be done at the secondary operation. The opening must be approximately one-half an inch or more wide. Then the necrotic shaft must be grasped by bone forceps and by a rocking motion, without too much lateral force, be freed from the periosteal shell. Then it can be crushed by pressure of forceps, and withdrawn piecemeal through the opening. Separation of the fragment at the epiphyseal end, as a rule, should be easy. If the shaft is firmly adherent to the end of the original shaft, very careful chiseling may be necessary to free it. The cavity in the periosteal shell can be cleaned out with 95 per cent. carbolic, followed by alcohol. The skin incision should be closed by chromic gut sutures, except for a small opening for a small gauze drain. Fixation must be continued for some time until the bone has become sufficiently rigid not to be broken by muscular action or slight blows. Complete closure of such a cavity demands a longer time than usually is taken for regeneration of a tibia, apparently because power of growth of the vascular involucrum centrally is less than its power of peripheral growth.

This operation is essentially the removal of a sequestrum from an involucrum, but it is the removal of an adherent sequestrum at an early stage, from a young involucrum which can grow centrally, and not the removal of a movable sequestrum from an involucrum of dense bone which has no such power. The latter and older method leaves a bony box which does not repair the defect.

### TREATMENT OF THE CHRONIC STAGE.

In this stage there exists usually an old necrotic shaft, usually worm-eaten, perforated by sinuses, and often freely movable, enclosed by a shell of dense, periosteal bone like the cortex of normal bone. Moreover, the ends of the sequestrum often are separated from the epiphyseal line and from the sound portion of the diaphysis by a layer of very dense bone which has arisen from the endosteum, and has completely occluded the marrow canal. This endosteal plug also is composed of dense bone like cortical bone; that is, the sequestrum lies in a complete box of endosteal and periosteal bone which has no power of central growth. Removal of the sequestrum may give drainage, but the defect fails to heal. Such a cavity usually is lined with dirty granulation tissue from which a constant discharge takes place. If the granulations are removed, the wall is seen to be dense white bone. Such a cavity may persist for many years; in one case seen by the writer it persisted for forty years.

Ollier showed by experiment on animals that normal periosteum was capable of regenerating an excised shaft of normal bone. Case 2, mentioned below, shows that, in the human subject, the periosteum at times is capable of regenerating a shaft removed during the acute stage of osteomyelitis. It seems possible that advantage of this regenerative power of the periosteum might be taken in cases of chronic osteomyelitis with a box of dense periosteal and endosteal bone. In chronic cases outside of the periosteal involucrum is a layer of approximately normal, although usually somewhat thickened, periosteum, which can be stripped from the outer surface of the involucrum. If the sequestrum and involucrum together are then removed, the inner surface of the periosteum then can be folded and approximated as in the operation during the subacute stage, with an excellent prospect of regeneration. It is to be borne in mind that, in these cases, when the entire shaft is not involved the medullary canal for some distance above and below the sequestrum undoubtedly is occluded by dense endosteal bone, of limited power of growth. Consequently it will be essential to chisel through this sclerotic bone until fairly normal vascular bone marrow is reached, otherwise there is danger either of great delay in union, or of failure of the regenerated periosteum to join the sclerotic ends of the shaft. In the only case in which I have had an opportunity to try this operation, in a somewhat modified form (see Case 12), the regeneration of bone was sufficiently complete to give a useful leg, although, probably for special reasons, a small sinus still persists. I believe that the prospects of complete cures in such cases are good enough to justify other attempts at the operation.

### ILLUSTRATIVE CASES.

The following clinical cases are presented to illustrate the feasibility of the operation, the constant periosteal regeneration and the excellent results which can be obtained. Where the cases were not my own, the name of the surgeon who operated has been given. My thanks are due to my colleagues on the staff of the Boston City Hospital for permission to present such cases:

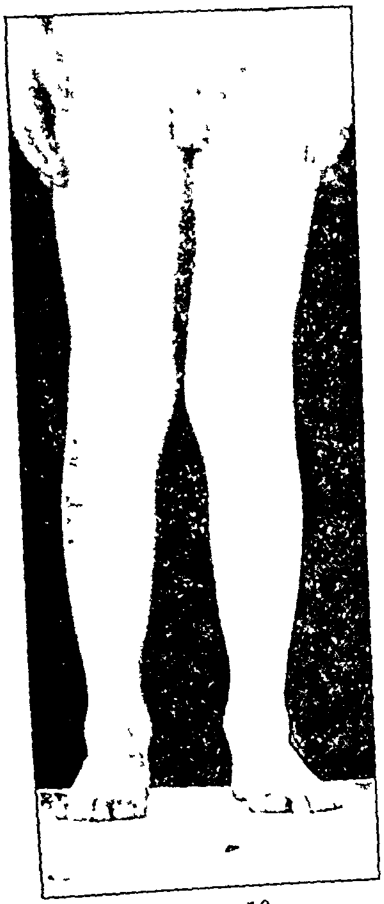

Figure 10.

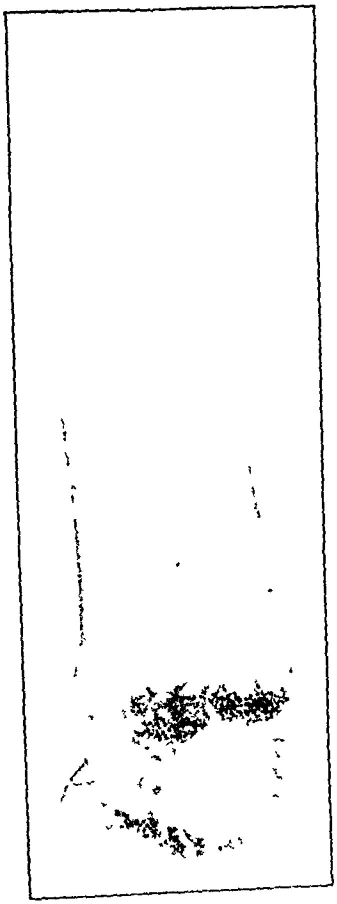

Figure 11.

Figure 10.—Case 1. Shows attitude, without atrophy or shortening. Scar of operation, inner side left thigh. Eight months after operation.

Figure 11.—Case 1. X-ray, left femur, side view. Slight change of density of bone, probably at upper limit of trephine hole in cortical bone. Eight months after operation.

Case 1.—W. J. D., boy, 4 years old. Case of Dr. J. C. Munro. Admitted to the hospital Aug. 5, 1902. Seventeen days before entrance fell while playing and bruised thigh. No known focus of infection. No symptoms for eleven days. Then sudden pain, soon followed by swelling of left thigh just above the knee joint. Pain and swelling increased, and some effusion appeared in the knee joint, which was flexed to within ten degrees of a right angle. Temperature 100.5, pulse 120.

*Operation.*—An incision three inches long was made on the anterior surface of the femur through skin and quadriceps muscle, with the lower end just above the upper limit of the capsule of the knee joint. The periosteum bulged, and when incised two or three ounces of thin yellowish pus escaped. The periosteum was stripped from the femur for a vertical distance of three inches, and apparently over the entire circumference. Shaft of femur was white and bare. Opening made through femoral cortex into medullary cavity gave vent to about one ounce of thin, oily pus. The opening was continued downward to the upper epiphyseal line of the femur, and extended upward to make an opening three quarters of an inch wide and three inches long. The medulla was not curetted or disturbed. Wound irrigated and closed about one-half by stitches at upper and lower ends. Wet dressing. Ham splint.

*Results.*—Immediate improvement in general condition. Local swelling rapidly subsided, and effusion into joint disappeared.

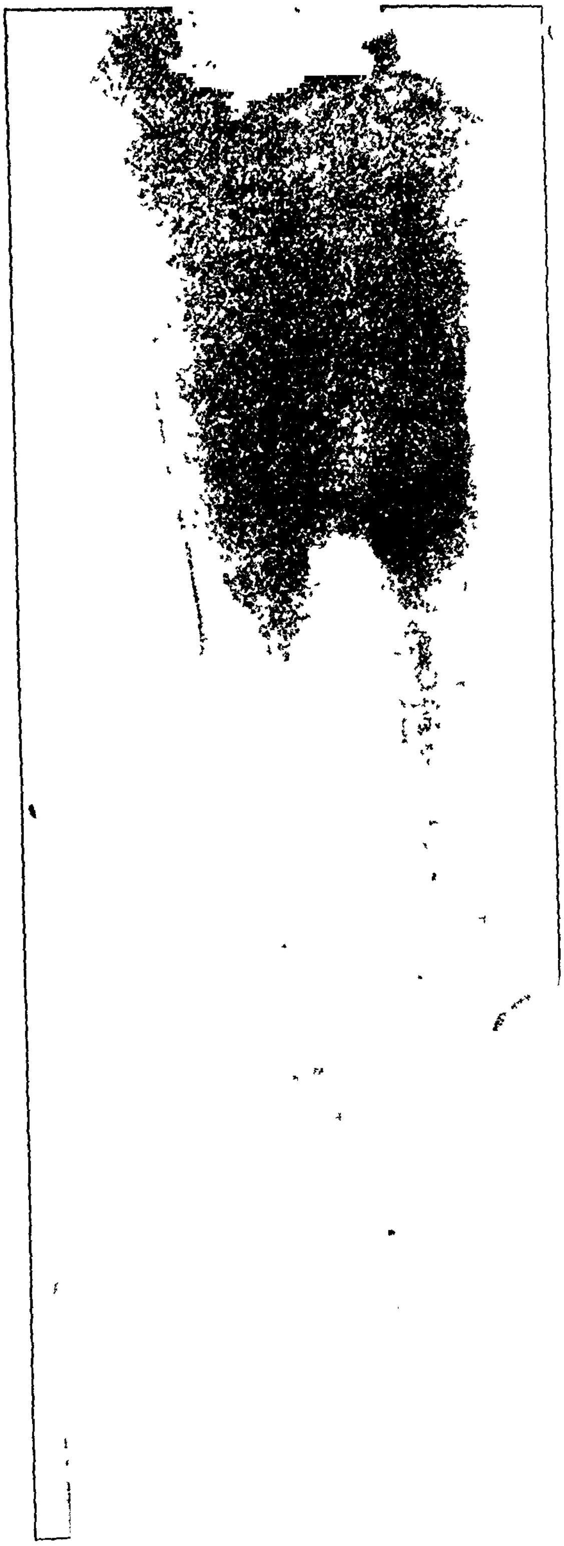

Figure 1
after opera
lar outline
periosteum

patient w
superficial
sinus was
charge an
time of o
pure cult

Examined April 2, 1903. Well-developed child, walks and runs without any limp. Over anterior surface of thigh a rather broad linear scar, not adherent to bone underneath. No shortening or atrophy of left leg or thigh. No tenderness. On palpation no thickening of femur can be made out. Motions at knee joint normal. Child has had no symptoms for months.

This case shows that in cases seen sufficiently early, before destruction of the marrow is too advanced, removal of cortical bone alone, without disturbing the endosteum, will give sufficient drainage to the bone, and, in some cases, will allow complete restitution of the bone without formation of a sequestrum. It also shows that the effusion seen early in many of these cases is not due to infection of the knee joint, but is a manifestation of inflammation only.

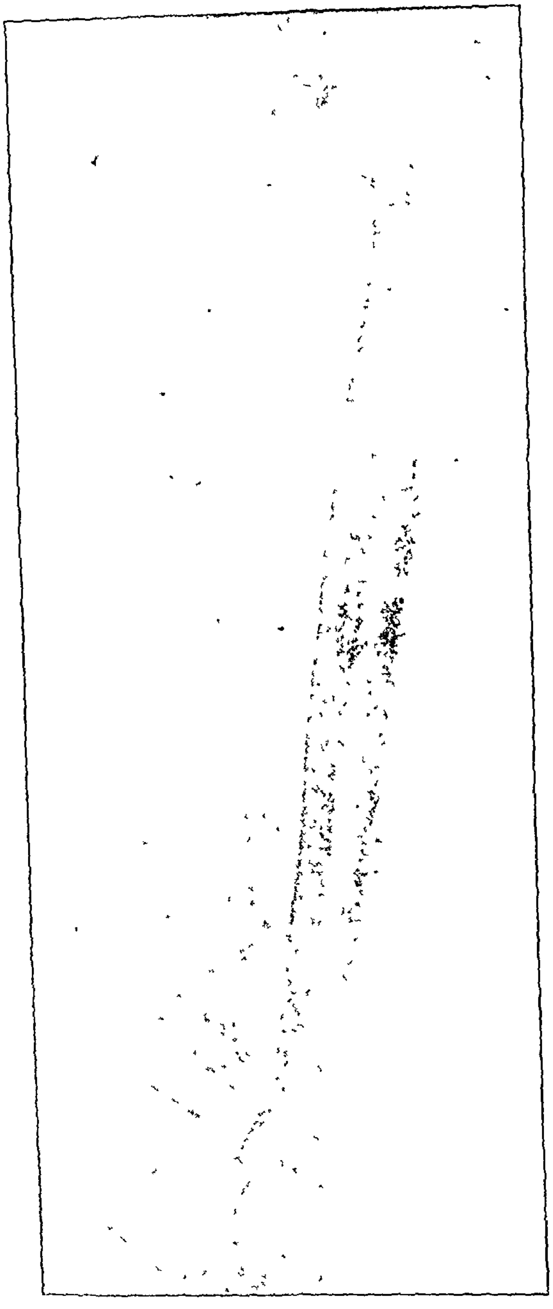

Figure 13.—Case 2. Left leg, *x* ray, side view. Eleven months after operation. Tibia regenerated except small portion of lower fourth. Antero-posterior bowing marked, probably because of difficulty of manipulating periosteum in acute stage.

Case 2.—A. S., boy, 4 years old. Case of Dr. F. B. Lun Admitted June 15, 1899. Three days previous to entran fell and bruised his left leg, without breaking the skin. Th next day the leg was swollen, tender and painful, and th patient had a chill. There was no known *focus of infection.*

At entrance the left leg was swollen from knee to ankl extremely painful, tender and edematous. Temperature 10

*Operation.*—June 16, an incision was made along the cres of the tibia from the tibial tubercle to just above the ankl joint. Hemorrhage was profuse. The periosteum bulged int the wound, and when incised gave vent to several ounces o thin yellow pus, and showed that the periosteum was almos entirely stripped from the tibia. The shaft of the tibia wa white and bare. The shaft was excised between the tibia tubercle above and the epiphyseal line below. The woun was partly closed by sutures, and a wet dressing and a pos terior wire splint applied. There was immediate improvemen in the general condition.

*Results.*—During the first few days there was considerabl discharge of pus, with some sloughing of the edges of th wound. The wound in a few days became a clean granulating trough, which closed from the bottom. The leg showed some tendency to outward bowing. On July 15, twenty-nine days after the operation, there was a fairly firm tibia from the tibial tubercle half way down the leg, and the wound was entirely healed with no sinuses. Two weeks later, forty-three days after operation, the upper three-quarters of the tibia was solid, while the lower quarter was elastic. August 13, two months after operation, the bone was solid except at the upper and lower ends. There was a small sinus at the lower end of the incision, at the junction with the epiphysis, and this sinus was dilated and two small fragments of necrotic bone were curetted out. On October 16 the patient was discharged wearing a plaster bandage. He had been about in plaster with crutches for some time. There was no sinus, and the new shaft was solid except at the junction with the lower epiphysis, where there was a slight elasticity. Every endeavor has since been made to find this patient, but without success.

This case shows the capacity of the periosteum to regenerate new bone nearly completely, even when the necrotic shaft is removed during the acute stage of the disease. The *x*-ray photograph, however, shows that the periosteum at this stage is not so easily managed in the large long bones, at least, as it is during the subacute stage.

Case 3.—P. R., Italian laborer, 20 years old. Admitted Oct. 17, 1902. Speaks no English and history of illness is imperfect. Five or six days previous to admission received a blow over the collar bone. Five days later pain and swelling over sterno-clavicular articulation. Swelling, pain and redness rapidly increased. Over right sterno-clavicular articulation a red, painful, fluctuating swelling about two inches in diameter. All motion of the arm painful.

*Operation.*—October 20. An incision about three inches long was made along the inner end of the clavicle, starting from the outer margin of the sternum. An abscess of the soft tissue was opened, which discharged about an ounce of thick yellow pus. The periosteum was stripped completely from its attachment to the inner two inches of the clavicle, was thickened, injected, but showed no bone in the deep layers. The cartilage of the proximal end of the clavicle was loosened. The inner end of the clavicle itself was soft, friable and contained pus. The sterno-clavicular articulation of the clavicle was freed, and the periosteum reflected from the inner two inches of the bone, and the bone was sawn across, removing the inner two inches. The abscess was curetted and made as clean as possible, and the periosteum of the clavicle was folded together and the edges approximated with catgut sutures. Wet dressing and Velpeau's bandage were applied.

Histologic examination showed acute osteomyelitis. Culture showed *Staphylococcus pyogenes aureus* in pure culture.

*Results.*—Eight days after the operation a superficial abscess developed under the right arm. Otherwise convalescence was uninterrupted and patient was discharged fourteen days after the operation with a small granulating surface over the middle of the incision and no sinus. The patient began to use his arm six weeks after the operation, and has worked as a laborer ever since Dec. 1, 1902.

Examination April 3, 1903, shows well-developed man with wide linear scar three inches long over inner end of the clavicle, beginning just inside the outer margin of the sternum. The clavicle appears normal except over one inch of inner extremity. There it is about half as thick again as normal, and is somewhat irregular in outline, not tender on pressure. Motion with the sternum is as free as on the unoperated side. All motions of the arm are normal. There is no pain on motion. Patient uses pick and shovel daily, and says he "can do everything but fight." Violent blow of fist, suddenly checked, causes a little pain at sterno-clavicular articulation.

This case is reported to illustrate the reparative power of the periosteum in the acute stage of osteomyelitis. In this case the difficulties in manipulating the periosteum were not so great as in the preceding case, chiefly from anatomic reasons.

Case 4.—J. W. D., male, 17, school boy. Four weeks previous to admission, without assignable cause, he was suddenly seized with intense pain about the right ankle. No known primary focus of infection. Swelling rapidly ensued and extended to the knee. There were repeated chills. An abscess opened spontaneously above outer side of right ankle after seven days, and one opened just below the knee three days later.

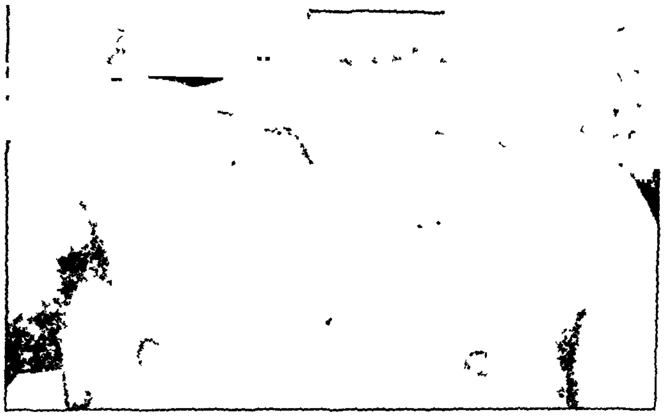

Figure 14.—Case 3. Six months after operation. Linear scar over inner end right clavicle.

Admitted Dec. 16, 1898. Patient showed signs of septic absorption. Right leg was swollen from ankle to knee, red, edematous and painful. There was a large sinus over the external malleolus, and a smaller one just below the tibial tubercle. Immediate operation was performed.

An incision was made four inches long over the lower sinus, and a similar one over the upper one, and two counter ones over the muscles of the leg. The tibia was bare, stripped of periosteum. Trephine hole into marrow through upper incision showed no pus, but "granulation tissue" marrow. Ankle joint apparently infected. Wet dressing and plaster.

Twelve days after the operation the foot showed a tendency to eversion. Immediate improvement in general condition followed the operation. Forty days after the operation an abscess appeared on the outer side of the leg from which pus was evacuated.

*Operation.*—Feb. 25, 1899, ten weeks after the primary operation, the secondary operation was performed by the writer. An incision was made over the crest of the tibia from the tibial tubercle to the lower epiphyseal line, and was carried down to necrotic bone. The periosteum everywhere was thickened, in some places being one-eighth of an inch thick, and everywhere showed in its deep layers new periosteal bone formation, crackling under the knife. The thickened periosteum was reflected from the tibia throughout the entire length of the shaft, except at the posterior tibial ridge, and various pus pockets were cleaned out with the curette. This was done to get rid of suppuration between the necrotic shaft and periosteum. The operation was checked at this point and a wet dressing and posterior splint applied, in order to give drainage and a chance for the extensive suppuration to diminish before removal of the shaft and closure of the periosteum.

Fourteen days later, the discharge and local infection having largely diminished, the periosteum was *entirely reflected* from the periosteum and the entire diaphysis of the tibia was removed, and the edges of the periosteum were approximated by catgut sutures. A wet dressing and a wire splint were applied. Daily dressing. There was some sloughing of the skin wound, especially over the lower third, with some eversion of edges. The upper two-thirds closed by first intention. There was *practically no pain after operation.*

*Results.*—Twenty-three days after removal of the shaft there was distinct bony induration along the line of the tibial shaft, which soon showed as a *cylindrical mass, and attained* a size apparently, to palpation, as large as the original shaft. This mass constantly grew more solid, and the patient was discharged June 21, 1899, a little less than four months after removal of the shaft. At that time there was no sinus or discharge, and the tibia was solid, although somewhat springy over the lower third. Induration, apparently bony, could be felt the whole length of the tibia. The patient wore a light plaster and used crutches. He was directed to return to the out-patient department at regular intervals. He came but two times, then began to walk on the leg. After some weeks an abscess appeared over the outer side of the ankle, which opened spontaneously, but gave practically no pain. This abscess apparently originated at or just above the point of union of the new shaft and the epiphysis. Considerable inflammation and induration of the soft parts about the ankle followed, and the foot flexed at the ankle joint. Since then

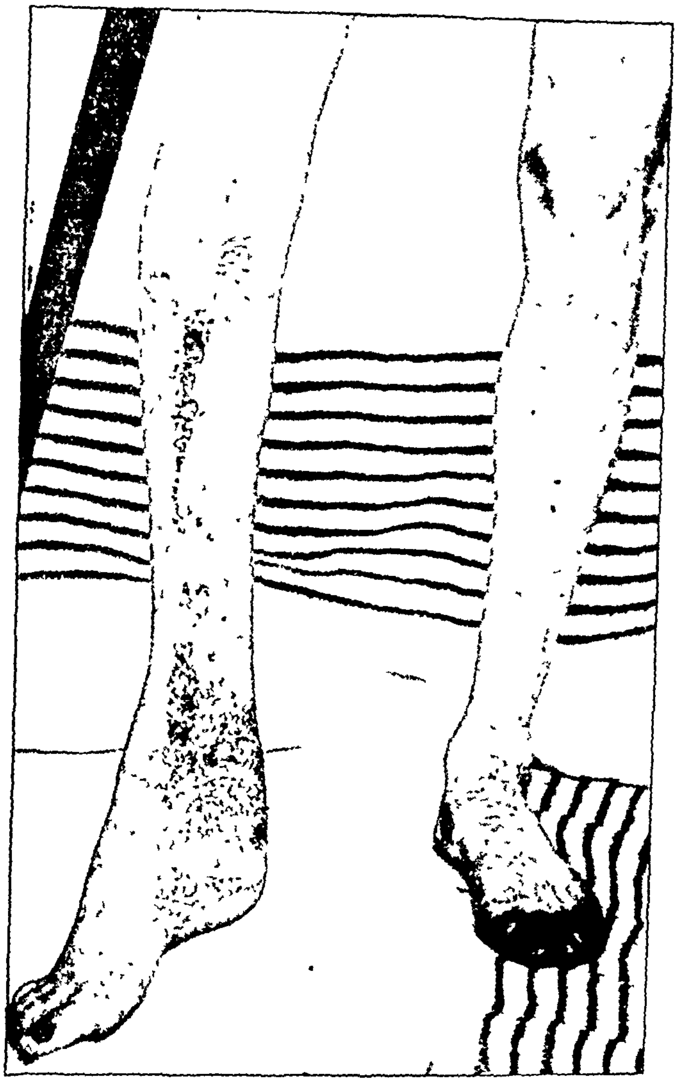

Figure 15—Case 4 Dark areas along scar of tibia and over ankle are not crusts, but are due to lack of cleanliness (*Notice toes of left foot*) Inside and behind internal malleolus is a small sinus.

the patient has walked on the leg, much of the time without any support, but at times with the aid of crutches.

At present there is considerable atrophy of the leg, with a quite rigid ankle, and foot flexed at the ankle joint and somewhat inverted. There are two sinuses, one at the outer side of the ankle joint and one over the internal malleolus. The tibial shaft is apparently complete throughout its length, and is firm and rigid, but feels considerably smaller than the normal tibia. The transverse diameter seems about the same as that of the other tibia, but the entire circumference is apparently less. This seems to have been due to some separation of the sutured edges of the periosteum.

The case is a functional failure, although the regeneration of the shaft was a partial success. The cause of the failure was apparently the development of a slight necrosis at the epiphyseal line and in the epiphysis, which, as has been said, is common. On discharge from the hospital, the result promised to be perfect, and the present state of affairs probably could have been avoided had after-treatment been followed up. The patient did not return because for a long time he suffered no pain, and because he has, even under present conditions, a fairly good functional leg. The *x*-ray shows that the diaphysis is much smaller than that of the normal leg. This may be due to a partial failure of the periosteum to regenerate, or may be due to the fact that the periosteum regenerates sufficient bone for function, as already mentioned.

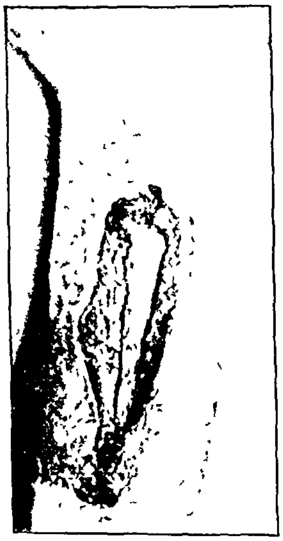

Figure 16.—Case 5. Left leg, two months after admission, one month before secondary operation.

Case 5.—D. A. (case of Dr. H. L. Burrell), 14 years old. School boy. Two weeks before entrance he bruised the calf of the left leg, without breaking the skin. After that time he had constantly increasing pain in leg, at first dull, later severe, and finally localized over the front of the leg, with onset of fever and stupor.

Admitted Oct. 21, 1899. Septic appearance and stupid. Temp. 101.8, pulse 120. Left knee and popliteal space red, hot, tender, edematous and swollen, and extending down over upper half of leg. Knee flexed almost to right ankle and swollen; patella floats.

*Operation.*—October 22. Multiple incisions about the knee and evacuation of a large amount of pus. Femur not involved. Incision over crest of tibia showed bone bare and periosteum elevated. Wet dressing. *Staphylococcus pyogenes aureus* present in pure culture.

*Results.*—Immediate general improvement. Profuse discharge of pus continued and shaft of tibia became brown and perforated.

Three months after this operation secondary operation was performed. An incision was made along the crest of the tibia from the tibial tubercle to two and one-half inches above the internal malleolus. Periosteum retracted and separated and entire diaphysis removed. The trough of slightly ossified periosteum molded into position and closed with interrupted sutures. Skin wound also closed and covered with silver foil. Sterile dressing, posterior wire splint. Tourniquet removed after the dressing. The first dressing was done on the tenth day. Upper and lower ends of incision healed by first intention with clean granulations over middle third. Thirty-seven days after the operation the leg showed formation of new shaft. One month later the leg was firm except for two small sinuses, one at junction of upper and one at junction of lower epiphysis with shaft. Parents refused to have sinuses curetted. On May 2, 1900, a little over three months after second operation, patient was discharged wearing a plaster, with crutches. The two sinuses still persisted, and there was slight mobility at the upper one.

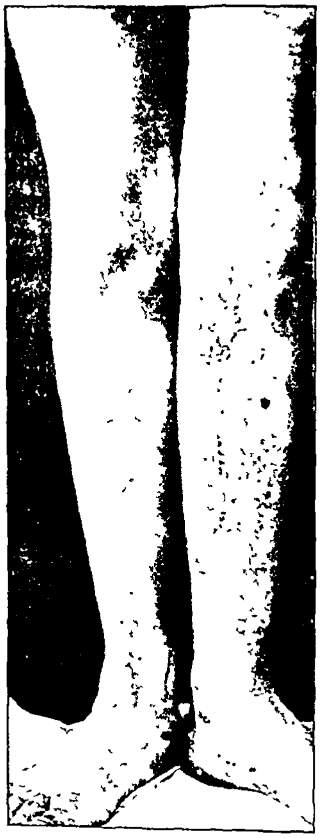

Figure 17.—Case 5. Three years after secondary operation. No shortening or atrophy. Linear scar over tibia.

The sinuses both closed in about four weeks, and the patient walked on the leg two months after leaving the hospital, and has done so ever since.

Examination in April, 1903, shows well-developed leg, no shortening or deformity or atrophy. A linear scar along the crest of the tibia. No sinus. No pain or subjective symptoms for two years. Tibia solid, of normal size, and by palpation is exactly like the sound one except for slight irregularity in contour. Perfect functional and cosmetic result.

This case shows practically perfect regeneration, after entire removal of diaphysis.

Case 6.—F. N., patient of Dr. G. H. Monks, boy of 14. School boy. Seven weeks before entrance seized with pain in left ankle, at first dull, soon becoming intense and throbbing. The next day swelling of leg. On the third day an incision into the soft parts over external malleolus and evacuation of pus. This gave some relief until six days before entrance, when there was an exacerbation of symptoms.

Admitted Sept. 15, 1898. The leg was swollen, with tenderness chiefly at lower end of fibula. An ulcer presented over the external malleolus. Fibula was bare over lower five inches and a profuse discharge of pus. Wet dressing and fixation to clean up the region for operation.

*Operation.*—One month later the secondary operation was done. An incision was made the whole length of the fibula. The entire diaphysis was removed. Wound was packed with gauze and a wet dressing applied.

*Results.*—Immediate improvement in general condition. The wound closed by granulation. Two weeks later two small sinuses persisted. Two months and ten days after secondary operation patient went out wearing a plaster. Boy walked on the leg about six weeks after leaving the hospital, and has done so since.

Examination in April, 1903, shows somewhat atrophied leg, with linear scar along entire fibula region. Fibula can be felt, apparently complete and firm. Perfect functional result.

Case 7.—H. S., 14 years old. School boy. Five days before admission spontaneous pain in right knee, very severe, so that he was unable to walk. Had chills and fever.

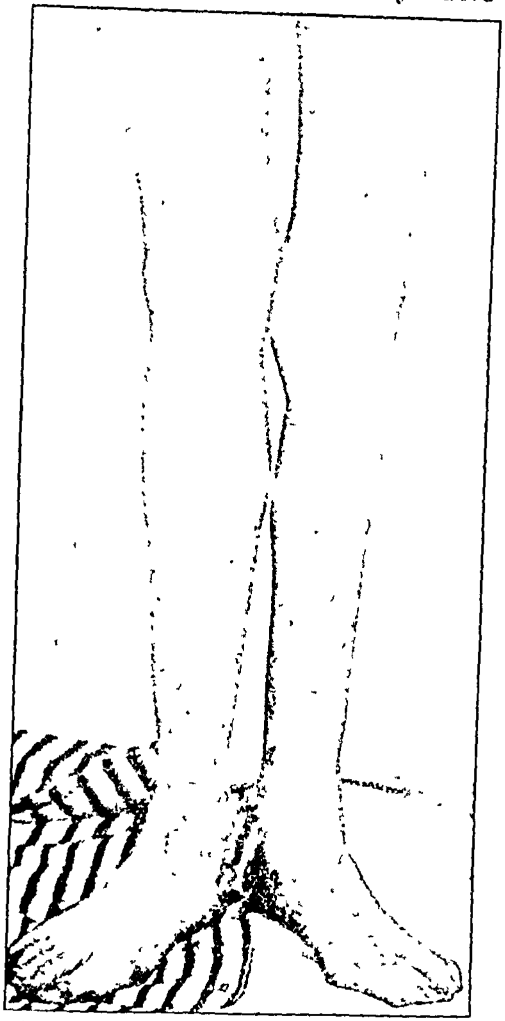

Figure 18.—Case 6. Removal entire diaphysis of left fibula. Four years after secondary operation. Considerable atrophy, about one-half of an inch shortening.

Admitted Sept. 14, 1900, for "typhoid fever." Stupor, mild delirium, leucocytes 8900, temp. 102.5. Three days later swelling of right leg from knee to ankle appeared and patient was transferred to the surgical ward. Leg swollen. Knee swollen and flexed. Cut six inches long over crest of tibia, beginning at tibial tubercle, evacuated much pus; periosteum bulging and tibia stripped. Trephine hole into tibia also evacuated pus from the bone. Opening enlarged downward three inches until no more pus escaped from the marrow. No attempt to close periosteal wound. Packed, wet dressing and plaster bandage. After operation, temp. 103, but normal on twelfth day. Wound closed by granulation, leaving bare bone at the bottom. Discharged November 13 with sinus, with direction to return for secondary operation.

*Operation.*—Feb. 7, 1901, he returned for the secondary operation. February 15 incision from tibial tubercle to junction of middle and lower third of leg. Upper third of tibia necrotic, periosteum thickened and crackling. Periosteum reflected from upper third of leg. Necrotic shaft removed from just below epiphyseal line to one inch below bottom of old trephine opening, until vascular marrow canal was reached. Upper end of lower fragment beveled off to allow approximation of lower fold of periosteum, but a triangular space had to be left between epiphyseal line and folded periosteum. Edges of periosteum united by interrupted chromic gut sutures. Skin wound closed with similar sutures. Dry dressing and plaster. First dressing in three days. Some sloughing of skin edges, approximated with adhesive plaster. Wound closed rapidly, mostly by first intention. Bony column first noted on eighteenth day. On twentieth day patient fell out of bed and struck the leg, and soon after an abscess developed on the outer side of the leg, connected with the triangular space just below the epiphysis, and a little necrotic bone was curetted out. Ten days later another fall, knee swelled, and patient began to have chills, and two months after secondary operation knee joint was opened and purulent fluid removed. Knee was drained by gauze wicks. From that time patient continued to improve, knee joint closed, and on Feb. 23, 1901, patient was discharged wearing a plaster, with firm tibia and a small sinus just below epiphysis. The sinus closed in about four weeks.

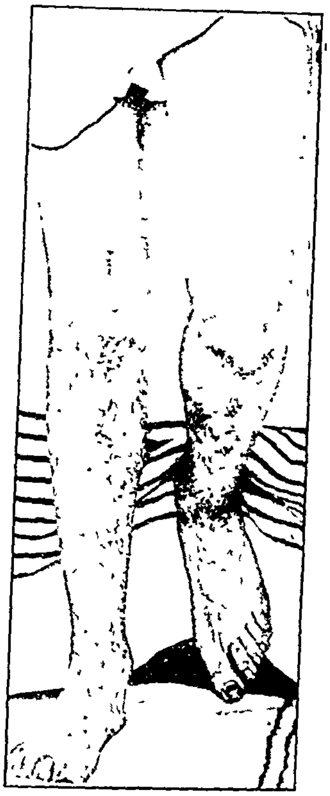

Figure 19.—Case 7. Removal upper third right tibia. Incision over knee joint and linear scar over upper half of tibia. Four years after operation.

*Results.*—The patient walked on the leg three months after leaving hospital, and has done so ever since, without any subjective symptoms.

Examination April 2, 1903, shows solid shaft of tibia without sinus, of practically normal size, possibly a little larger than the normal tibia and a little irregular in outline. No tenderness. Motions at knee joint perfect, except for a diminution of flexion by less than ten degrees. Scars of incision over tibia and into joint healed. Walks without limp. Perfect functional and cosmetic result.

This case shows the possibility of removal and regeneration of a necrotic portion of the shaft. It also illustrates the possibility of an infection of the knee joint by extension, and, furthermore, shows that the last place to heal usually is the interval just below the epiphyseal line.

Case 8.—R. L. T., female, 24 years old. Nurse. Twelve years previously sprained left ankle. Four years previously broke both bones of left leg, tibia just above the ankle and fibula at the middle. Six months after fracture had pain and swelling about left ankle and a small bit of bone was discharged through a spontaneous sinus. Sinus healed in two months. One year later another attack of pain, and a small spicule of dead bone removed by operation. From that time on had recurrent attacks of pain, often severe.

Admitted Oct. 24, 1900. Painful, tender swelling over lower third of left tibia with scar of old operation. Rest in bed and poultices. Radiograph showed no bone focus, and patient went out with pain relieved on November 1. She was comfortable for a few weeks, when pain recurred.

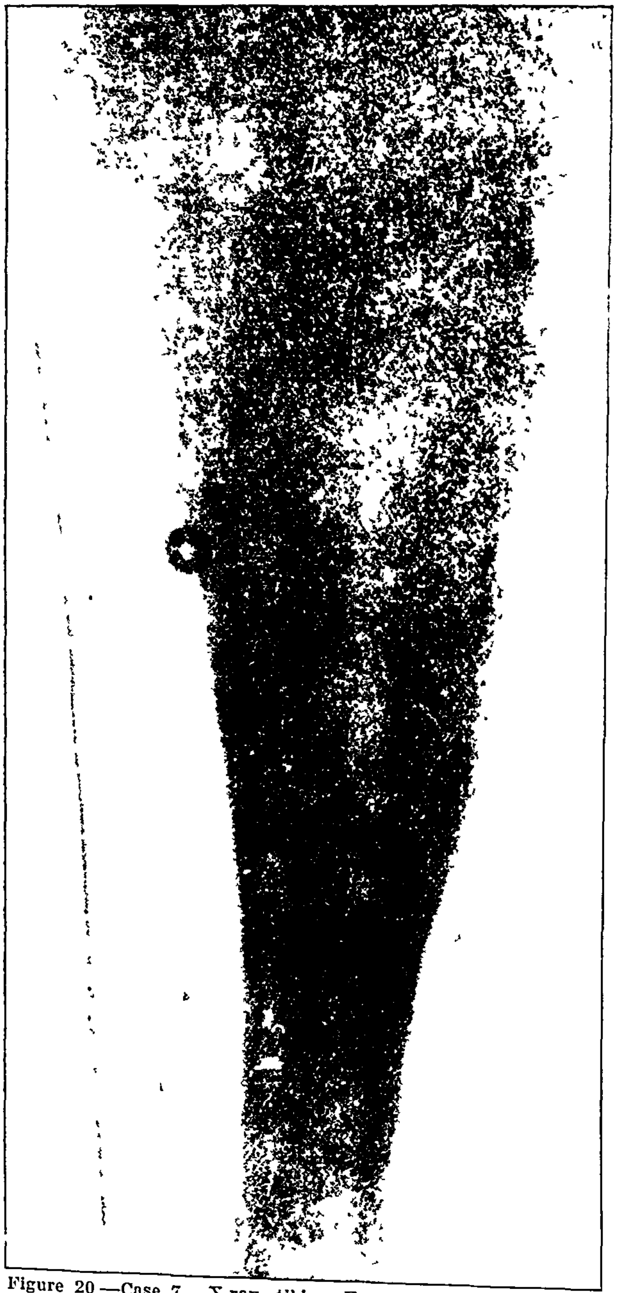

Figure 20.—Case 7. X ray, tibia. Four months after primary drainage operation. Front view. Marked thickening from formation of periosteal bone.

She was readmitted June 23, 1901, with tender tibia and limited ankle motion. June 26, 1901, an incision was made by the surgeon then on duty and a trephine hole made above and below the epiphyseal line. From the upper trephine hole a thin pus escaped, and the lower one opened into a thin-walled bony cavity filled with pus. The cavities were packed and a wet dressing and plaster bandage applied. The wounds in soft tissue closed by granulation, but the discharge from the sinuses was profuse and great swelling of the soft parts ensued. Amputation was considered

*Operation.*—July 23, 1901, the writer operated. There was a sinus leading into a cavity in the lower end of the diaphysis, filled with pus and granulations. There was a similar sinus and cavity in the shaft of the tibia about four inches above the epiphyseal line. The two cavities did not connect. The cortex of the tibia between the two trephine holes was white, stripped of periosteum and necrotic, forming a fixed adherent sequestrum. The posterior portion of the cortex of the lower four inches was closely adherent to the periosteum. The periosteum was thickened and showed moderate periosteal ossification. The shaft of the tibia was removed from the epiphyseal line to about an inch and a half above the upper sinus, except for a thin layer of cortical bone at the bottom. The marrow canal above the sinus was closed by rather dense scar bone, and the tibia was removed until the upper limits of this endosteal dense bone was reached, i. e., until vascular marrow was reached. A thin strip of cortical bone adherent to periosteum was left at the bottom of the cavity, because it

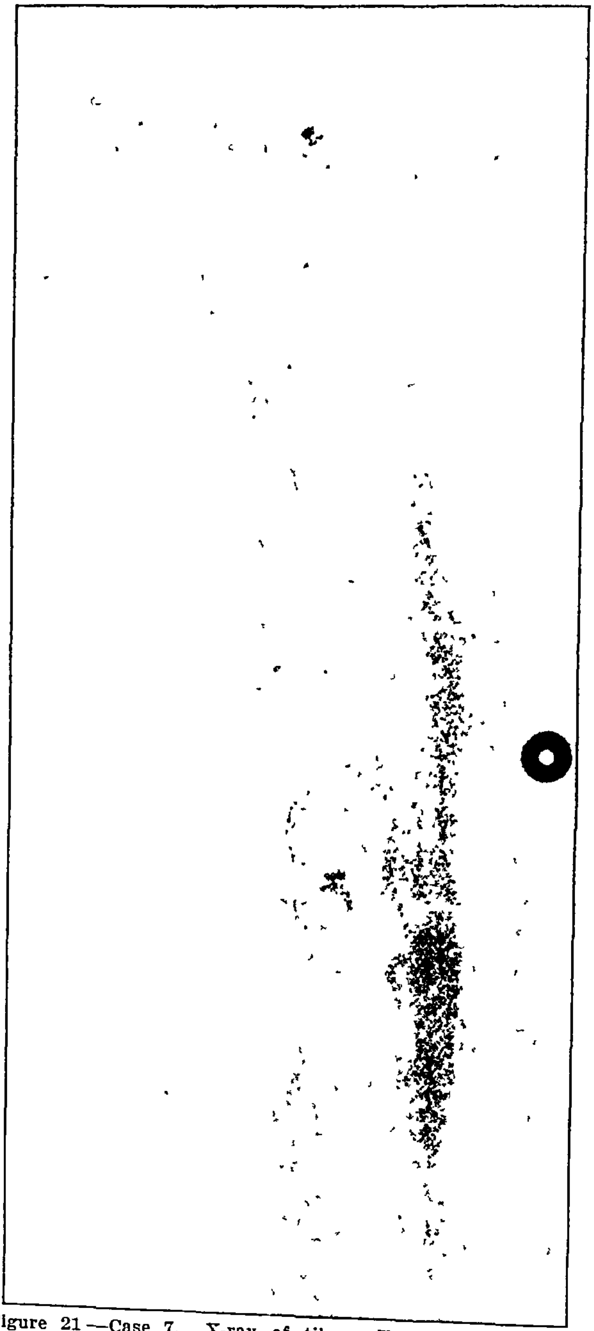

Figure 21.—Case 7. X-ray of tibia. Two months after secondary resection, upper portion of tibia. Side view. Regeneration of bone most marked posteriorly. Beveling of lower fragment is obvious.

was thought that this thin layer was viable on account of its attachment to the periosteum, and would serve to preserve the contour and length of the limb. This strip of periosteal bone was about one eighth of an inch thick and one-half an inch wide. (See Fig. 30.)

All soft infected tissue was carefully curetted and the cavity was sterilized by 95 per cent. carbolic acid, followed by alcohol. The lower end of the upper fragment was beveled off to allow as accurate as possible apposition of the periosteum. The thickened crackling periosteum was approximated by three chromic gut and one silver wire suture which passed about the cortical remnant and outside the periosteum. There was a triangular dead space unavoidably left just above the epiphyseal line, and, of course, a similar smaller space just above the strip of cortical bone. The defect in the soft tissues was closed by sliding a skin flap across laterally and fastening it by interrupted gut sutures. A wet dressing and a plaster were applied.

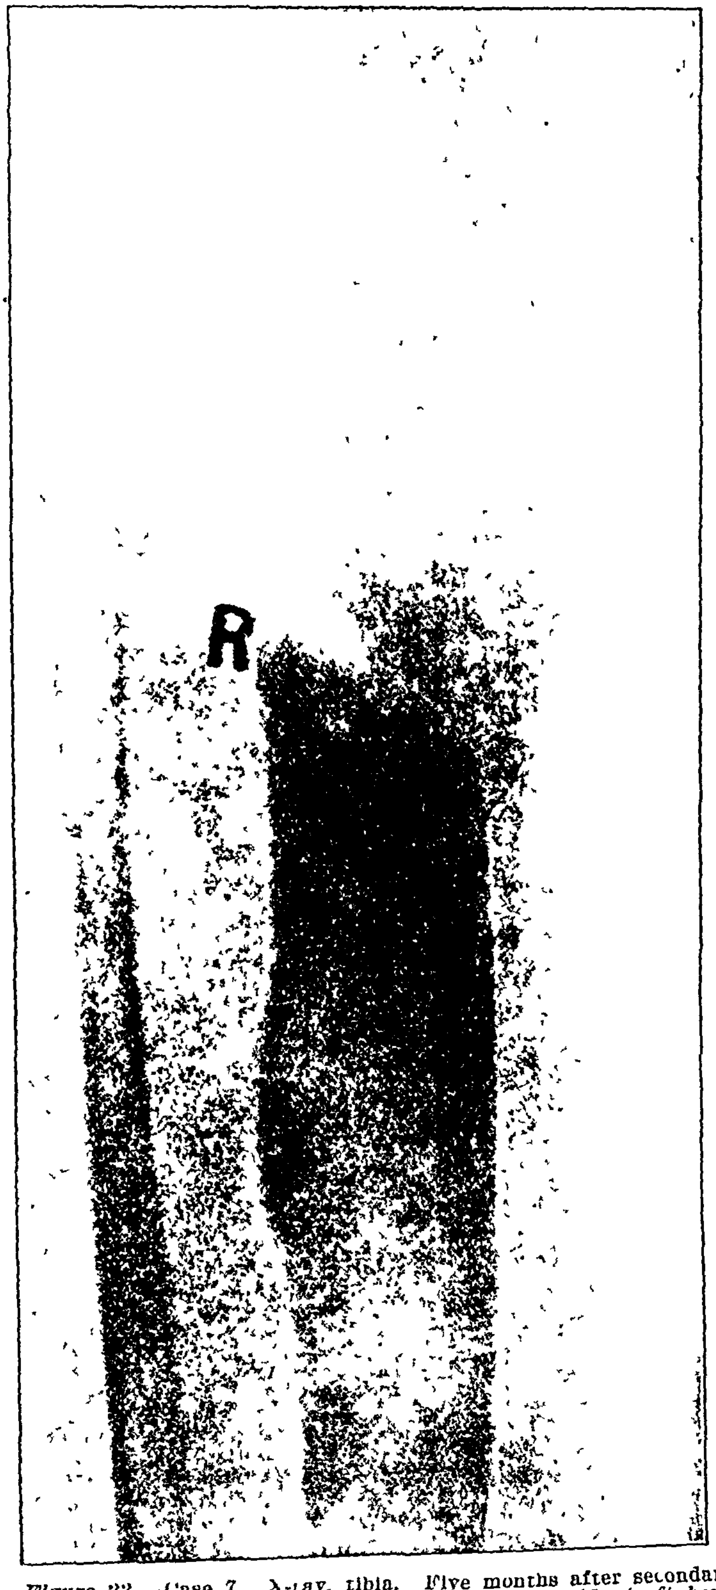

Figure 22.—Case 7. X-ray, tibia. Five months after secondary resection. Front view. Upper end of bone very wide (soft bone with overgrowth). Marrow canal not evident.

There was some sloughing of the edges of the wound, and after about two weeks a sinus developed just above the epiphyseal line. The upper part of the wound closed by first intention. Suppuration from the sinus was profuse for three weeks. Two months after the operation a cylinder of fairly solid bone could be felt completely filling up the defect. Sinus had closed almost to level of the skin, and patient left the hospital Sept. 26, 1901, two months after operation, with plaster bandage and crutches. The sinus closed promptly, and the leg was comfortable for about two months. Then several small abscesses developed over the silver suture, which finally was removed in December, 1901. In January, 1902, the leg was completely healed and the patient walked without support. With the beginning of warm weather small abscesses again appeared, and on standing or walking the leg was painful. In July, 1902, a sinus developed and the patient came to the hospital. July 10, 1902, the sinus was curetted and found to extend outside the periosteum to a bit of apparently bare bone on the outer surface of the new shaft. This bare bone probably was some fragment of the cortical strip left behind at the operation. The wound closed slowly by granulation, but the discharge and pain continued and the leg swelled.

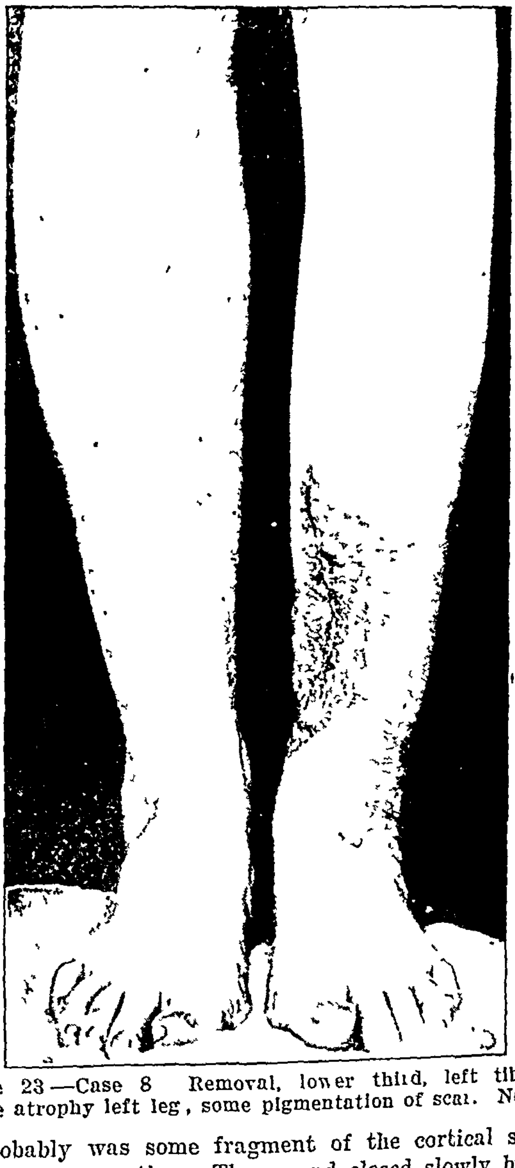

Figure 23.—Case 8. Removal, lower third, left tibia twice. Moderate atrophy left leg, some pigmentation of scar. No sinus.

Aug. 7, 1902, an incision five inches long was made along the old scar. The periosteum was one eighth of an inch thick. There was some suppuration of the surface of the newly-formed *diaphysis*. The periosteum was reflected. The new diaphysis was solid bone with no medullary canal. Fearing that there would be little power of repair of this dense bone, four inches, i. e., nearly all of the new solid diaphysis, were removed from just above the epiphyseal line up to vascular marrow. The periosteum was approximated by interrupted chromic gut sutures, and the wound of the soft tissues was closed. Wet dressing and plaster were applied. There was considerable pain for six days after the operation, referred to the external malleolus, the soft tissues over which were opened. Patient was mildly delirious for several days. There was almost no discharge from the wound in front of the tibia. Five days after the operation the patient was removed from the hospital, during my absence, against advice.

After leaving the hospital another abscess developed on the outside of the leg. This healed in three weeks. By Oct. 1, 1902, solid bone had appeared and sinuses were closed. In December patient walked with a cane. Since March, 1903, patient has walked without bandages or support.

*Results.*—Examination in April, 1903, showed patient walking without limp or pain. The leg is a trifle smaller than the sound one, and shows a little anteroposterior bowing in the lower third. The leg is one half inch short. The scar is completely healed; there has been no sinus for six months. Tibia is solid throughout, width is a little greater than that of the normal tibia, but diameter on the whole seems a little less. There is, however, marked posterior bowing of tibia at the site of the operation.

The case is of particular value. At the first resection of the tibia I think it was a mistake to leave the posterior shell of cortical bone, as probably the persistent formation of abscesses was due to a failure of all of that shell to retain its vitality. The regeneration of bone by the periosteum, however, was complete, and, in fact, more perfect than it was after the second resection. The second resection was done practically on an unossified periosteum, and the regeneration has been fairly successful. The suppuration which followed, however, apparently caused some gaping and separation of the infolded periosteum, and explains, I think, the backward bowing of the new diaphysis. The case also illustrates the undesirability of unabsorbable metal sutures. The functional result is at present perfect, and the cosmetic effect nearly so. The case emphasizes the extraordinary regenerative power of the periosteum at any stage of the disease.

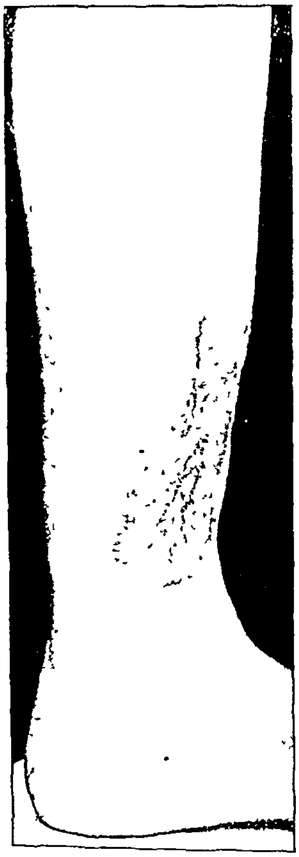

Figure 24.—Case 8 Removal, lower third, left tibia twice. Very slight antero posterior bowing of left leg in lower third.

Case 9.—J. P. R. School boy, 14 years old. Sixteen days before admission he bathed in very cold sea water. Three days later pain in left shoulder, soon becoming severe. Swelling appeared in a few days. Temperature became high and repeated chills. Admitted to the medical side as "articular rheumatism." Soon transferred to surgical. Temp. 103.4, pulse 124. Septic appearance and mental stupor. Left shoulder and upper arm much swollen, red, edematous and exceedingly tender and painful on motion or pressure.

May 12, 1900. Incision six inches long from tip of acromion to lower insertion of deltoid muscle. Subcutaneous tissue edematous. Deltoid fibers were separated and showed bulging periosteum. Incision of periosteum evacuated several ounces of greenish pus. A one-half inch trephine hole through the cortex, just below upper epiphyseal line, gave vent to several drams of pus. Trephine hole enlarged down to the deltoid insertion until pus no longer escaped. Marrow was dark red and gelatinous. Marrow was not curetted nor disturbed. The wound was packed open with iodoform gauze and a big wet dressing and Velpeau bandage applied. *Staphylococcus pyogenes aureus* was present in pure culture. Immediate im-

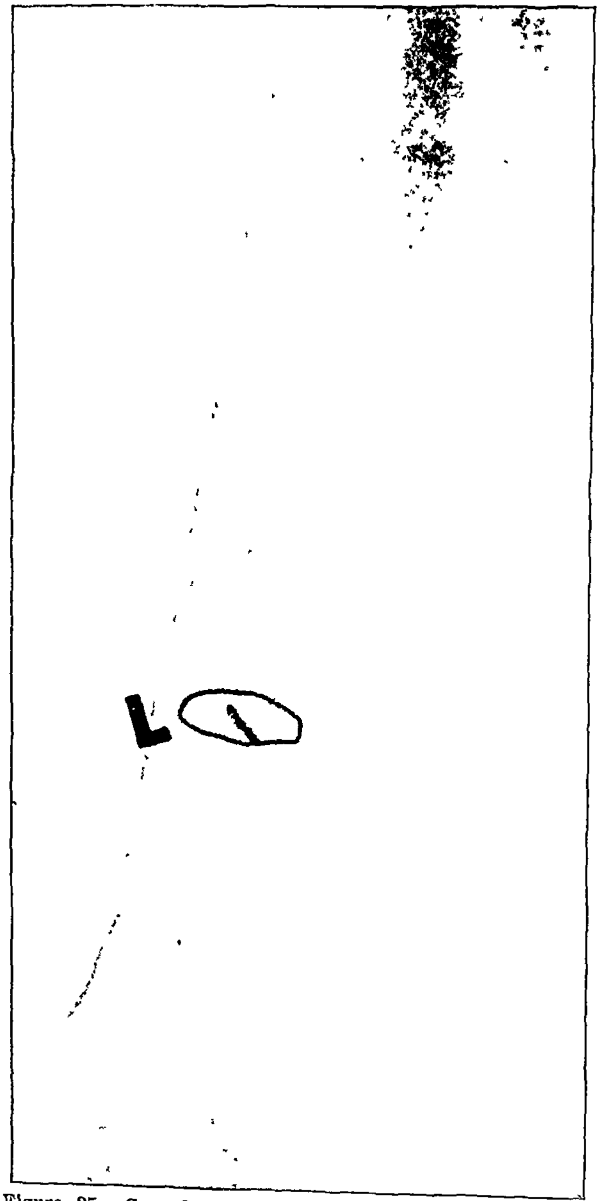

Figure 25.—Case 8. X-ray. Removal, lower third, left tibia twice. Six weeks after first removal of lower third of tibia. Shows tapering of upper end of tibia, silver wire suture and deep layer of cortical bone

provement in general condition. Wound closed by granulation, but a sinus leading down to bare bone persisted. The patient was discharged two weeks after the operation, to come in later for secondary operation when periosteum had sufficiently thickened to maintain contour of limb.

Patient returned eighteen weeks after discharge, i. e., twenty weeks after the primary operation. Sinus meanwhile had been carefully kept open to allow of very free drainage. There was no limit to passive motion nor any pain. X-ray photograph showed much periosteal thickening outside the necrotic shaft.

*Operation.*—Sept 28, 1900. An incision five inches long made through the old scar and sinus, beginning one inch below the tip of the acromion The granulations of the sinus were curetted and the edges excised. The necrotic old shaft was lying in a cylindrical cavity of periosteal bone about one half inch thick. The shaft was free at the upper end, but firmly attached below. The necrotic shaft was removed in two pieces with chisel and gouge and forceps, through the opening in the periosteal shell left over the old trephine holes, and was about three and a half inches long. The cavity had walls of vascular young periosteal bone. The cavity was packed with iodoform gauze. The shell was sufficiently rigid to maintain the contour of the limb.

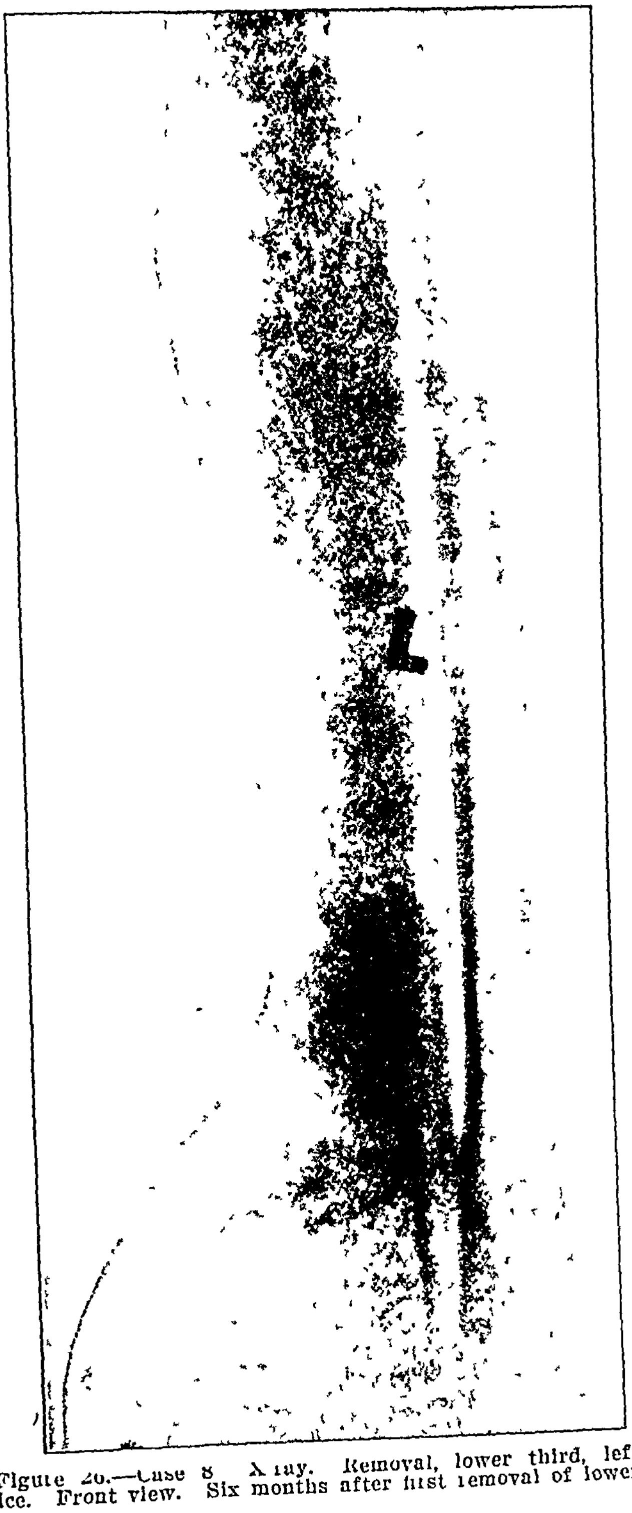

Figure 26.—Case 8 X ray. Removal, lower third, left tibia twice. Front view. Six months after first removal of lower third of tibia

The cavity closed rapidly from the first and by the end of two weeks was healed nearly to level of skin and no bare bone could be felt. Seventeen days after the operation the patient was discharged with a granulating wound, wearing an internal angular splint.

Three weeks later a small sinus developed at the bottom of the scar, and a small bit of bone was discharged Ten weeks later a similar sinus occurred with discharge of a small bit of necrotic bone. The sinus did not completely heal for six months after the operation

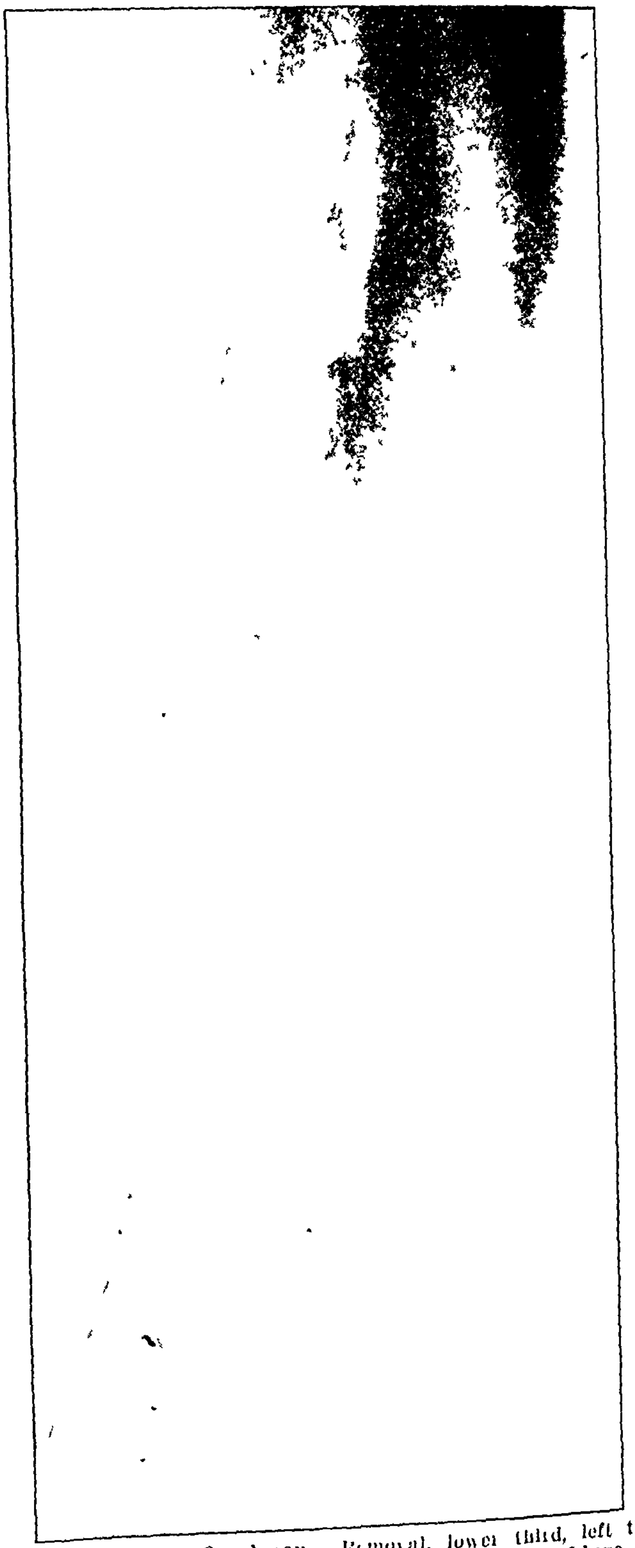

Figure 27—Case 8 X ray Removal, lower third, left tibia twice Lateral view Nine months after first removal of bone

*Results.*—Examination in March, 1903 Arm has been completely healed for over a year. Wide linear incision extends from tip of acromion to the insertion of the deltoid, largely due to a separation of the deltoid fibers by the scar. The humerus is solid throughout, of apparently normal size, but a little more irregular than the normal humerus Passive motion at the shoulder is unlimited. Voluntary motion is perfect except in elevation of arm from the side, due apparently not to loss of muscular power, but to separation of deltoid fibers Functional and cosmetic effect nearly perfect.

The case illustrates the power of central growth of the earliest stage of the periosteal shell, in marked contrast to the lack of such power that is seen in old involucra, after conversion into ivory bone.

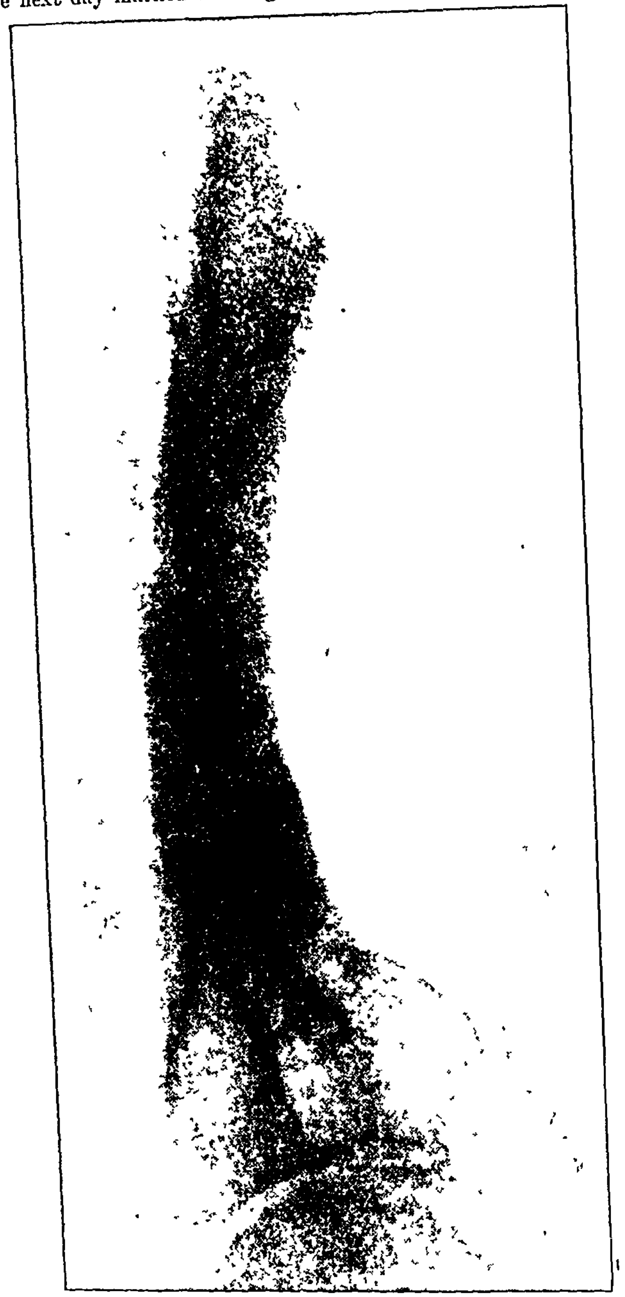

Figure 28.—Case 8 X-ray. Removal, lower third, left tibia twice. Lateral view. Nine months after second resection

Case 10.—G. Z., 18 years old. Brass finisher. One week before admission a pimple appeared on chin, below the tip. The next day marked swelling of face. Admitted Oct. 8, 1900. Much swelling of left side of face and chin, with edema, swelling, redness and pain. No swelling in mouth and all teeth sound or filled on affected side. An incision of soft parts was made, evacuating about an ounce of pus. The edema and pain continued to increase, and a few days afterwards a second incision was made along the lower edge of the ramus of the jaw and a small piece of the internal shell of the ramus was removed. The boy was discharged eight days later with a discharging sinus leading down to necrotic alveolus, and urged to return for observation. After leaving the hospital all of the teeth except the last molar on that side became loose and came out, and a considerable piece of the alveolar process was removed through the mouth. The bone of the jaw of the left side rapidly increased to double normal size from formation of periosteal shell. Dead bone could be felt through sinus in mouth and through external sinus.

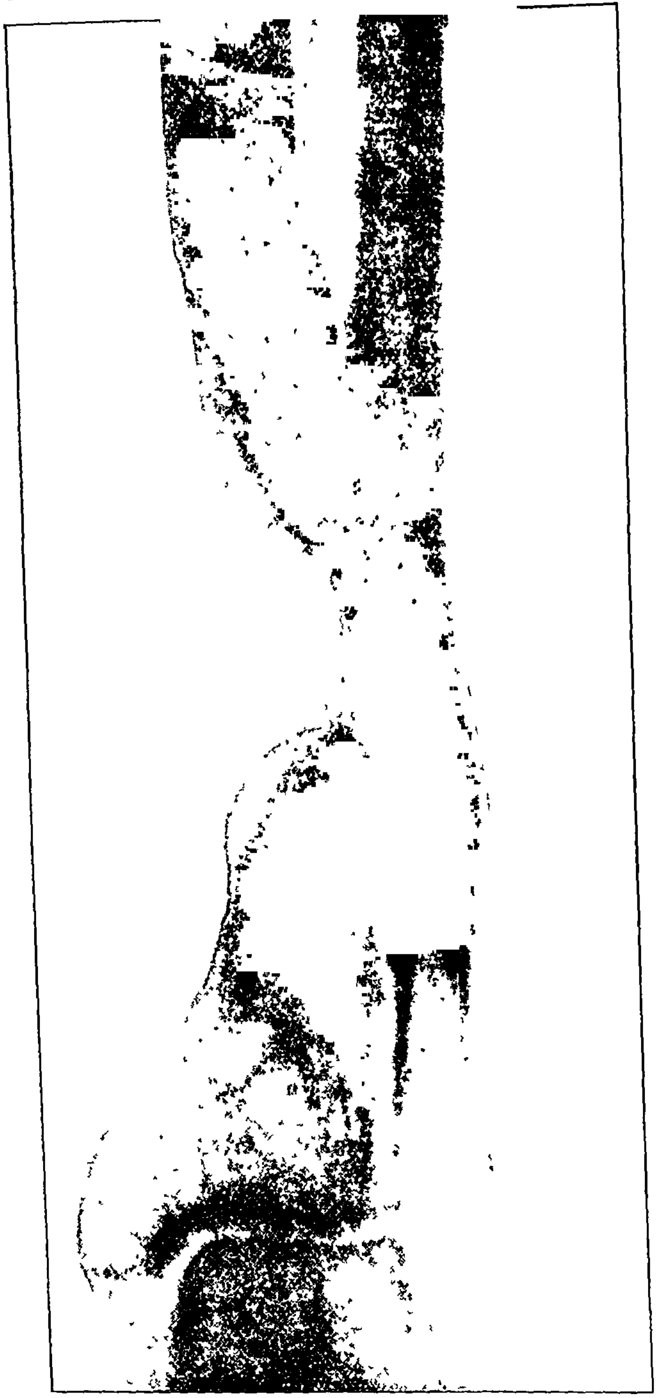

Figure 29.—Case 8. X-ray. Removal, lower third, left tibia twice. Front view. Nine months after second resection.

March 13, twenty weeks after primary operation, patient was readmitted. Jaw of left side nearly double normal size and causes marked deformity. The sinus below the left ramus persists. The thickening is almost entirely bony thickening, with but little edema of the soft parts. The jaw was at that time considered to be rigid enough to allow removal of necrotic ramus, and yet young enough to allow of probable central growth.

*Operation*—An incision made from in front of the angle to nearly the tip. Periosteum was thickened to about one-quarter of an inch and quite rigid. A trephine hole, half an inch in diameter, was made near the tip of the jaw through the periosteal bone, and the opening was enlarged backward. Beneath the shell was necrotic ramus, surrounded by pus, and this was removed in one piece about two inches long, beside some smaller fragments. The cavity was curetted to remove all fragments of dead bone, and the cavity was closed except for a small wick in front. The wound closed by first intention except for the wick. The patient was discharged eight days later.

*Results.*—A month later a small abscess formed near the angle of the jaw, which apparently did not connect with dead bone, for it healed promptly after incision. The sinuses closed in about three months, and ten months after the operation the jaw was markedly reduced in size.

Examination April 15, 1903, shows the outline of the face nearly normal, as bony thickening of jaw has quite disappeared. Linear incisions along lower edge of ramus. Last molar on that side remains. All other teeth gone in lower jaw to first molar on opposite side. Ramus of normal thickness laterally, but not so thick vertically as normal, apparently because alveolar process did not regenerate. No sinus for a year and a half.

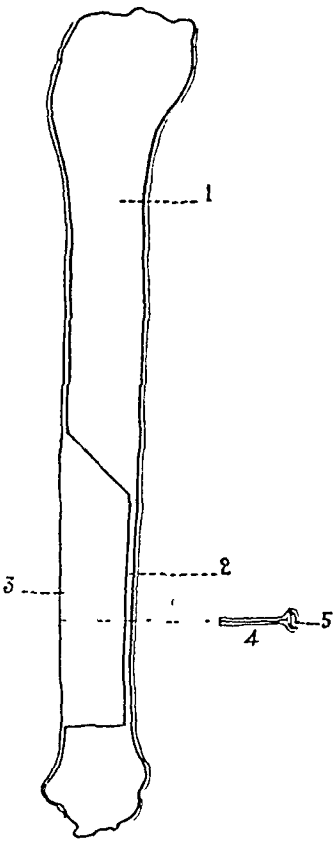

Figure 30.—Diagram to illustrate amount of bone removed in Case 8. 1. Upper portion of normal diaphysis. 2. Layer of cortical bone not removed at first resection. 3. Upper level of infolded periosteum. 4. Transverse section through infolded periosteum and posterior strip of cortical bone. 5. Posterior strip of cortical bone.

This case, like the preceding, shows the power of central growth of the early periosteal shell.

Case 11.—C. C., Italian, housewife, 24 years old. Speaks no English and history is imperfect. When 14 years old bruised the leg. Shortly after the leg swelled, patient was very sick, and an abscess formed, which broke and discharged pus and dead bone ever since at intervals.

Admitted Oct. 22, 1900. At the upper end of right tibia marked swelling and tenderness. Scar of previous injury. Very painful. Joint motions normal.

*Operation.*—Oct. 24, 1900, an incision was made over crest of tibia, opening an abscess of considerable size in the soft parts. Bone was covered with thickened periosteum, 1/16 inch thick. Periosteum was retracted and tibia of nearly double normal size, very dense and hard, exposed. A trephine hole through a cortex of more than double normal thickness opened a pus cavity, containing about half an ounce of yellow pus. The marrow canal was practically occluded above and below this cavity by dense endosteal bone. With chisel and gouge the cavity was enlarged upward and downward until vascular marrow was reached. The cavity was cleaned out with 95 per cent. carbolic acid, followed by alcohol. All of the abscess wall also was curetted and carefully removed The cavity was filled with blood clot according to Schede's method The clot broke down and disintegrated and left the cavity lined with pale, unhealthy granulations.

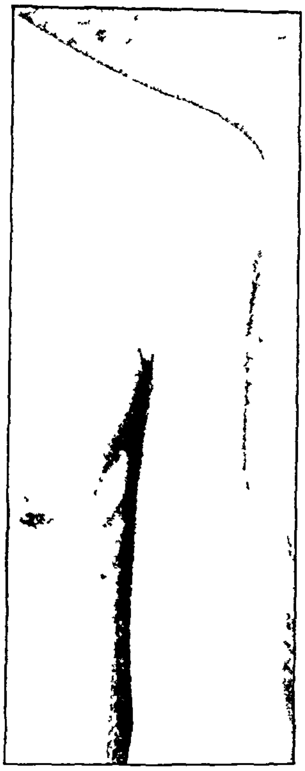

Figure 31.—Case 9 Removal upper half diaphysis, left humerus Three years after operation

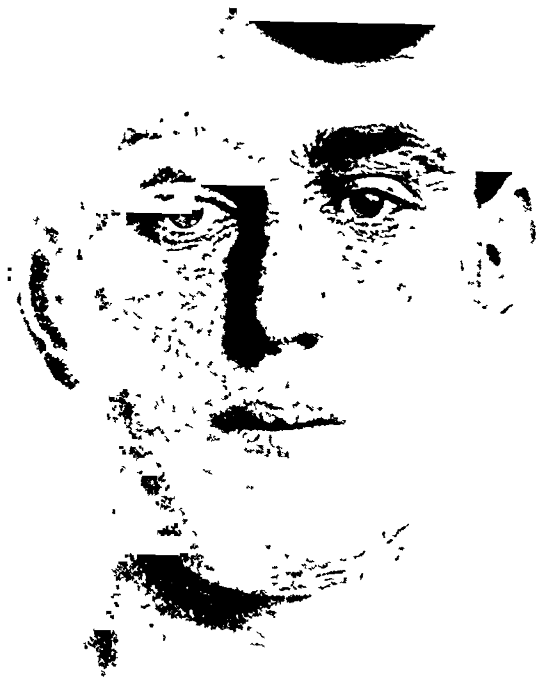

Figure 32.—Case 10 Front view. Thirty months after removal of two and one-half inches of ramus of left lower jaw. Contour of face has returned nearly to normal.

Nov. 28, 1900, an attempt was made to utilize the regenerating power of the periosteum to obliterate the bony defect

An incision six inches long was made along the crest of the tibia, including the sinus. The periosteum was reflected and the dense tibia removed for a length of about four inches, except for a thin layer of cortical bone, attached to the periosteum, at the back of the tibia, as in Case 9. The tibia was practically all ivory bone and no definite marrow canal was seen, but the cavity was enlarged in both directions until the dense bone became more vascular. The periosteum then was approximated and sutured, although a triangular dead space had to be left at the junction with each portion of the shaft. The skin also was sutured and pressed firmly on the bone. A large plaster bandage was applied.

*Results.*—There was some sloughing of the edges of the wound at the middle of the incision, but upper and lower portions healed by first intention. Bony thickening was evident at the end of forty days, although a small sinus persisted. The patient was discharged wearing a plaster three months after the operation with a rather soft tibia of about one-half normal size, and a small sinus, in which dead bone could not be felt. The patient walked on the leg four and one-half months after the operation, and has done so ever since.

Examination April 2, 1903. Patient walks without limp. Leg is considerably smaller than normal leg. There is a marked concavity of the leg, beginning just above the tibial tubercle and extending down to the middle. The tibia is firm, not tender, a little wider than the normal tibia, but of about one-third less diameter. There is a slight vertical trough in the front surface of the bone, in the middle of the incision. It has not been possible to get the patient to come for an *x*-ray picture.

The case is not a complete success. The regeneration of the tibia has been sufficient to give a satisfactory functional result, but the persistence of the sinus is disappointing. I suspect that the cause is the cortical strip that was not removed.

The cases above presented are not selected cases, except Cases 1, 2, 5 and 6. Those cases were operated on bv other surgeons, and by their permission have been presented here because they illustrated some special feature of the process of bone regeneration. The cases do include all of my own cases of disease of the large bones operated on by the method previously recommended, in which sufficient time has elapsed to determine the result of operation, except one case of resection of the inner half of the clavicle for tubercular disease. In that case there was complete regeneration of the removed portion of the clavicle, with a satisfactory sternoclavicular articulation. I have also in a few cases operated on small bones, e. g., phalanges, by this method, and succeeded in obtaining complete healing and regeneration. There has been a considerable number of cases operated on by this method by other surgeons at the Boston City Hospital, with exceedingly satisfactory results.

### CONCLUSIONS.

A careful study of the cases here reported will show that the following statements in regard to the treatment of osteomyelitis are justified:

1. In the acute stage of osteomyelitis, drainage of abscess in the soft parts alone is not sufficient. The bone marrow is infected, and must be drained. Removal of a sufficient amount of cortical bone alone is all that is required to give perfect drainage to the bone marrow. Curettage and disturbance of the marrow cause extensive destruction of the endosteum, which, if left alone, has in a limited number of cases operated on early, sufficient power of regeneration to repair the bony defect without the formation of a sequestrum. Under those circumstances a very early operation on the cases is necessary.

2. In the subacute stage it is desirable to remove the necrotic shaft, completely or partially, at an early stage in order to take advantage of the power of regeneration of the periosteum. The periosteum either before or after the beginning of periosteal ossification has the power of regenerating a completely or partially removed shaft of bone.

3. For mechanical reasons the manipulation of the periosteum is easier after ossification of the periosteum has begun, but while the membrane still is plastic. Moreover, the rapidity and surety of perfect regeneration seem greater at that time.

4. The operation consists of an incision through skin and ossified periosteum down to necrotic shaft, reflection of the periosteum, removal of the shaft, either entire or partial, folding of the plastic periosteum in such a way as to approximate the internal layers, suture of the edges by absorbable sutures, suture of the soft tissues, with, in both cases, provision for moderate drainage and complete immobilization.

5. The success of the operation is naturally greater when asepsis is provided for by careful drainage preceding the operation and by careful removal of all infected material and tissues at the time of operation.

6. After removal of the necrotic shaft well-marked ossification of the new periosteal shaft appears between the twentieth and fortieth days, and the shaft is solid enough for use in locomotion in from four to eight months. If the epiphyseal line is extensively destroyed, considerable shortening of the limb may result.

7. The regenerating bone at first becomes much larger than the original shaft was and is entirely composed of solid periosteal bone, with no marrow canal. This enlargement probably is due to the fact that the bone is less completely calcified than it is later. In time the size of the bone decreases almost or quite to that of the original shaft, and, finally, judging from *x*-ray photographs, a marrow canal is formed. This fact suggests that the size of bones may be due to two factors, heredity and environment, and that the ultimate size of the bone, therefore, is due to the function required of it.

8. The chief difficulty in completing the restoration of the shaft is to obtain complete union of the regenerated shaft to the epiphyseal line or to the portion of the normal shaft that remains. Slight necrosis and suppuration may persist at this point after the repair otherwise is complete, and may demand minor operations to remove small fragments of necrotic bone. Union at these points may be delayed, but ultimately always has taken place.

9. The best time for the operation ordinarily is about two months after complete drainage of the acute infection.

10. This operation is the operation of preference, and is especially applicable when an accessory bone which can act as a splint is present.

11. The anatomic, functional and cosmetic results obtained by this operation are much superior to those obtained in any other way in cases of large bony defects due to acute infection of bone.

12. Where no accessory splint bone is present *it may be impossible, in special cases, to maintain the contour* of the affected bone by the above-mentioned method. In such cases advantage can be taken of the power of central growth possessed by the shell of periosteal bone in its *early* stages. This means that the necrotic bone must be removed just as soon as the periosteal shell is sufficiently advanced and solid to maintain contour and bear the weight of the limb. Roughly, this stage is reached when the thickness of the periosteal shell is equal to one-quarter of the diameter of the original shaft.

13. The time when this condition exists can be determined by *x*-ray examination and by palpation.

14. If the necrotic shaft is removed at this time it leaves a solid cylinder of periosteal bone, very vascular, but partly calcified, analogous to the bone seen in an early external callus, and this shell has sufficient power of central growth to fill up large cavities. The rate of central growth seems to be markedly slower than that of peripheral growth. Persistence of sinuses is longer than in the preceding method, partly from a delay of closure of the cavity, and possibly from a failure to remove small fragments of necrotic bone at the time of operation.

15. This method of operating leaves at first bone very much larger than the original bone, but, as in the preceding case, ultimately the bone diminishes in size and slowly approximates that of the original bone.

16. In the chronic cases more or less sequestrum surrounded by an enormously thick shell of dense cortical, more or less ivory-like bone, exists.

17. The power of repair of dense cortical bone is very slight or practically wanting. Removal of sequestra leaves a more or less extensive cavity in bone, surrounded by a wall of dense bone, lined with unhealthy granulations, which has no tendency to close.

18. The most satisfactory methods ordinarily recommended for the closure of such defects are the aseptic blood clot, or obliteration of the cavity and approximation of skin flaps. The aseptic blood clot aims to fill the defect with dense scar tissue, but does not lead to regeneration of bone, and requires for its success greater asepsis than ordinarily can be obtained in extensive osteomyelitis. The skin flap method may close the cavity, but does so at the expense of great bony destruction.

19. From one semi-successful case, from a consideration of the general process of regeneration of bone by the periosteum, and the successful results obtained in the subacute cases, it seems likely that better results can be obtained by removal of both sequestrum and involucrum and the use of the regenerative power of the periosteum.

20. In removing a portion of a shaft under such circumstances, the excision should be carried sufficiently far into the normal shaft to get above a medullary canal, occluded by dense, ivory bone, and reach vascular marrow.

21. Finally, the most satisfactory results in treatment of acute osteomyelitis can be obtained by complete drainage of soft tissues and marrow in the acute stage, with the removal of extensive necroses, if they occur, at a secondary operation undertaken about two months later, and by adaptation of the regenerative power of the periosteum for the formation of a new shaft.

## THE WANING GLORY OF THE LEUCOCYTE.

As the chief hero in the contest between the bacterium and the man, the leucocyte seems to be suffering the fate of many another shining light of battle, and its once high position is being most vigorously assailed. At first, the only means of defense against bacteria that had once gained a foothold and begun to multiply, so far as known, was the intrepid leucocyte, which was supposed to attack the most virulent bacteria, engulf them while in full activity and either to digest them or die in the attempt. Through the work of Metchnikoff and his school, particularly, this power of the leucocyte was made familiar to all, and the subject was elaborated vigorously. It was not long, however, before voices were raised in opposition, contending that the leucocyte was not so much of a hero after all, but merely a scavenger that picked up the bodies of dead or crippled bacteria and destroyed them, but was unable to give much protection against bacteria that were virulent. The injury to the bacteria, according to these investigators, was essential for successful phagocytosis, and was accomplished by soluble substances present in the serum which possessed marked bactericidal powers. Thus arose two schools—the humoralists and the supporters of the phagocytic theory. Naturally enough most of the French pathologists followed Metchnikoff and their work was influenced by his ideas, while the Germans were solidly lined up on the opposite side.

At last the defenders of the leucocyte were forced to recognize the actual fact of the presence of bactericidal substances in normal blood plasma, and they then fell back to the ground that, although the leucocyte could pick up and destroy virulent bacteria, yet they were much better able to accomplish this if the organisms had been previously injured, and that the substances that injured the bacteria were produced and secreted by the leucocytes. Destruction of bacteria, they contended, was the function of leucocytes, which was accomplished either intracellularly after phagocytosis, or extracellularly by bactericidal products of the leucocytes, or by combining the two processes. As a compromise that recognized the potencies of the serum, this view met with considerable favor, particularly as there were many features of immunity that bore it out, and Buchner, Gruber and others were convinced that "alexin," the bactericidal constituent of blood plasma, was a product of the leucocytes and in nature like a proteolytic enzyme. Ehrlich and his school, by showing that the alexin of Buchner really represents two uniting substances, the "complement" and the "intermediary body," made necessary further modification of the leucocyte's part in immunity, which developed in the form of an assumption that the complement, which bears much resemblance to a ferment, was the contribution of the leucocyte, particularly the polymorphonuclear neutrophile.

But even this last shred of honor is threatened, and particularly by the interesting studies of Petrie.[1] Using the method of Rowland for obtaining the inmost constituents of cells, which consists of triturating the cells after they have been made brittle by exposure to the temperature of liquid air, he obtained extracts of leucocytes. Although this process does not destroy the bacteriolytic properties of normal serums, the extracts of the leucocytes so obtained were found to be entirely devoid of bactericidal powers, showing that they contained nothing resembling an "alexin." Neither did they contain anything in the shape of a bactericidal "complement," for they could not reactivate the normally bactericidal serum that had been deprived of complement by heating. This was found to be the case with the leucocytes of the normal rabbits when tried against typhoid bacilli, for which the serum of rabbits is powerfully bactericidal, and the leucocytes of rabbits rendered highly resistant to typhoid bacilli by immunizing were equally devoid of alexin or complement. From these experiments, which are in accord with others performed by different methods, it appears that Metchnikoff's view that the bactericidal substances of blood exist in the bodies of the leucocytes to be liberated on their destruction, can not be accepted. There remains still the possibility that the leucocytes really do secrete bactericidal substances, but that they do not exist preformed within the cell. In other words, they resemble the inactive zymogens that become active on or after secretion.

In any case, however, there is a strong tendency, based on good grounds, to rob the leucocyte of much of its former significance. Yet it is still to be contended that the leucocytes must have some function, and this is almost certainly connected with the resistance of the body against infection, and even if it does not happen to be just what Metchnikoff thought, yet it is probably of importance, else why the leucocyte?

---

## OCHRONOSIS.

In a former issue[2] we reviewed editorially the important features characterizing the anomaly known as alkaptonuria. It was pointed out that Garrod regards it as a "sport" or an alternative mode of metabolism. Until a very recent date the only clinical significance that alkaptonuria possessed rested in the fact that a number of the cases had been mistaken for diabetes mellitus, owing to the power the urine possessed of reducing copper solutions. Due consideration of the other characteristics of the urine should have obviated this mistake, however. The vast majority of the patients have no symptoms referable to the anomaly, and it appears to have no tendency to shorten life.

---

[1] Jour. of Path. and Bact., 1903, ix, 130.

[2] The Journal, Jan. 30, 1904, p. 313.

Recent observations indicate that a pathologic condition of great interest and rarity is associated with and probably due to the metabolic disturbance in alkaptonuria. Osler[2] has just reported two cases of ochronosis, or pigmentation of the cartilages, in alkaptonuric brothers, both of which cases have already been published in the literature as alkaptonurics, and constituting two of the four instances of this anomaly observed in this country. In 1866, Virchow described a remarkable blackening of the cartilages in the body of a man, aged 67 years, who had died of aneurism, and suggested the name "ochronosis" for the condition. Previous to the two cases here referred to, only seven instances have been recorded. One or two of them were described as having melanuria, but Albrecht,[3] who reported the seventh case in 1902, deserves the credit of first suggesting an association between the disease and alkaptonuria. The urine of his patient was dark colored and reduced sulphate of copper solutions, but hemogentisic acid was not absolutely demonstrated.

Osler's first case is a man 57 years of age. At the present time the sclerotic coats of the eyes show areas of black pigmentation in the exposed portions. The cartilages of the ears, particularly the concha and helix, show a remarkable blue-black discoloration. A noteworthy feature not previously recorded is that a butterfly shaped area of the skin over the nose and cheeks is also markedly pigmented, the pigmentation resembling powder marks very closely. The discoloration of the sclerotics and of the ears was present but less marked eight years ago. The other brother, 49 years of age, presented a similar but less striking pigmentation of the sclerotics and cartilages of the ears. The patient had noticed the pigmentation for several years. There is little doubt but that the deep-seated cartilages of both these patients would manifest the same changes.

The probabilities are that ochronosis is another manifestation of the metabolic disturbances in alkaptonuria, which previously had been recognized only by the urinary changes. Some of the cases of ochronosis have not been associated with alkaptonuria, and Garrod thinks it is possible that there may be two distinct classes. An interesting fact is that Ogden's alkaptonuria case, another of the four American cases, has just been found to have the ochronotic pigmentation. Whereas all alkaptonurics do not have ochronosis, it will probably be shown that all ochronosis cases exhibit alkaptonuric changes in the urine.

## ABSORPTION OF TUBERCLE BACILLI FROM THE ALIMENTARY TRACT.

It is frequently urged, as an argument against Behring's theory as to tuberculous infection taking place through the intestinal tract, that if this were true, then primary tuberculous lesions in the intestines of tuberculous children and adults would be a common finding at necropsy instead of a very rare one.

Koch's paper at the London Congress, in which he asserted that no case of tuberculosis can be considered of alimentary origin unless a primary tuberculous lesion is found in the intestinal tract, gave a new impetus to the controversy over this question as long ago as 1890. Dobroklonski, working under Cornil, had practically proved that tubercle bacilli can pass through an intact intestinal mucosa, for he demonstrated the presence of tubercle bacilli in the solitary follicles, the mesenteric lymph glands and liver of guinea-pigs, which had been fed on glycerin bouillon cultures of this bacillus, and whose intestinal mucosa proved to be without demonstrable lesion. Dobroklonski, however, was unable to discover the path traveled by the tubercle bacilli. This missing link was supplied by Nicholas and Dercas, in Arloing's laboratory, who fed fasting dogs a mixture of greasy soup and milk in which had been incorporated large quantities of potato culture of tubercle bacilli. The dogs were killed about three hours after feeding, the chyle collected from the thoracic duct and injected into the peritoneal cavity of guinea-pigs. Positive results were obtained from two of the six dogs.

Still more convincing results have just been obtained by Ravenel,[1] bacteriologist to the State Live Stock Sanitary Board of Pennsylvania. He was led to this investigation by having repeatedly observed extensive lung lesions in animals fed with tuberculous material, in whom the intestinal lesions were either absent or very slight. Ravenel followed the procedure of Nicholas and Dercas, using healthy fasting dogs, and preparing them by purgation and a twenty-four-hour fast. A single dose through the stomach tube was then given of an emulsion of warm water and melted butter with which tubercle bacilli in large numbers had been mixed. The dogs were killed after three and a half to four hours, the chyle and mesenteric glands removed, and used for the intraperitoneal inoculation of guinea-pigs. Eight of the ten dogs gave positive results, all of these having been inoculated with bovine tuberculosis of the twenty-ninth or thirtieth generation only, while the two negative ones had been given cultures of human tuberculosis of very low virulence—of the one hundred and forty-second generation. Tubercle bacilli were demonstrated microscopically in the chyle and glands from three of the dogs, but none of the ten showed the smallest intestinal lesion. The chyle and mesenteric glands were used to inoculate twenty-four guinea-pigs, and in twenty-one of these tuberculosis was demonstrated by microscopic as well as macroscopic examination.

---

[1] Jour. of Med. Research, vol. v, December, 1903, p. 460.

From these experiments, Ravenel concludes that infection from tuberculous food may take place without a primary intestinal lesion, and that the most favorable condition for such infection is the ingestion of infected foods rich in fats. As the bacilli pass into the chyle and are largely carried into the blood stream through the thoracic duct, it is easy to understand how infection through food may show itself first in the lungs, while the infection of the solitary follicles and mesenteric lymph glands, observed by Dobroklonski, is also easy to explain.

Apparently, therefore, we have experimental proof that, in the lower animals at least, pulmonary tuberculosis may be contracted through the ingestion of milk infected with tubercle bacilli, and that the lesion may be primary in the lungs, the intestines showing no lesions. There is no reason to suppose that the same thing may not be true of human beings also.

## SOME FURTHER OBSERVATIONS ON ULTRA-MICROSCOPIC PARTICLES.

Some time ago[1] we commented on a new method for the observation of ultra-microscopic particles. The method was first described by two German physicists, Siedentopf and Ziegmondy. The principle is the lateral illumination of the particles by an intense focus of light. With a microscope particles thus illuminated can be seen as small as 0.005 micron and even smaller. The method was first applied to observe minute particles of gold in a piece of glass. It was suggested at that time that it would be of value in the study of colloidal solutions and also of biologic problems.

Raehlmann[2] has recently reported some interesting applications of this method. In studying solutions of pigments he finds that there are present numerous very minute particles. Particles of different colored pigments not only vary in color, but are also characterized by different form and movement. This fact may be of great service in the dye industry on the analysis of pigments. In a mixture of dyes, the resulting color, in some cases, depends on the formation of new particles whose color, form and movement differ from the particles of either of the original dyes. In other cases, the resulting color depends on the arrangement of the color components, the particles of one color forming an envelope about the particles of the other. This arrangement of particles, he says, appears to be the result of the electromagnetic forces of attraction and repulsion.

These facts are undoubtedly of great importance in the staining of tissues, for we must consider the changes that are brought about by the addition of these particles in the stain to the particles in the cell. The apparent structure may be considerably altered in this way. Then, again, we may study by this method the action of stains on the simple constituents of the cell, such as albumin, carbohydrates, etc. Aqueous solutions of egg albumin, which are homogeneous under the highest power of the ordinary microscope, by the new method show a great number of very minute particles from 5 to 10 microns in size. A very high dilution, 1 to 100,000 or more, is used. All the particles are in rapid continuous vibration, and remain always the same distance apart.

This method can be used for the determination of albumin in urine. Not only its presence is detected, but a quantitative estimation can be made. From the character of particles observed in the urine, even a method for the differential diagnosis of the various forms of nephritis is predicted.

Solutions of carbohydrates, such as gum arabic, dextrin, grape sugar and milk sugar, show innumerable fine particles, which, for the most part, polarize light. Aqueous solutions of diastase show particles about the same size as carbohydrate particles, but differ from them in form and movement. Glycogen is highly interesting. With a dilution of 1 to 3,000,000, sufficient particles can be seen to indicate the presence of glycogen. The particles have a characteristic grayish-white color, and are in extremely rapid vibratory motion, which decreases as the dilution increases. The transformation of glycogen into grape sugar under the influence of diastase can be observed under the microscope. The particles of glycogen disappear, and in their place are seen other particles much fewer in number and having an entirely different appearance.

Such facts as the above can not fail to excite the interests of scientists in general, and especially the physicist, chemist and biologist. Certainly these extremely minute particles must be somewhere near the magnitude of molecules of colloids. At least, a tremendous stride has been taken in that direction. Statements denying the possibility of ever seeing molecules must be reconsidered. Who can say but that ultimately we may not be able to observe the mechanics of a chemical process with the eye? Apparently, an entirely new field has been opened up for many branches of science, and this through the application of extremely simple principles.

## SENSITIZING BACTERIA TO THE FINSEN LIGHT.

In a recent communication,[1] Dreyer of Copenhagen reports certain experiments of therapeutic interest on the bactericidal action of erythrosin—one of the eosin stains—in connection with the Finsen light. He finds that the addition of a very small amount of erythrosin to the culture media of bacteria and infusoria causes a very much greater sensitiveness on their part to the yellow and green rays (which are otherwise comparatively ineffective), and that it acts not only directly on the organisms in the cultures, but through a thick layer of integument as well, in this way destroying the *Bacillus prodigiosus* in twenty minutes. He recommends the use of a one per thousand sterile solution of the Grübler erythrosin in normal salt solution, the injection to be made according to Schleich's method at the site of the disorder; the Finsen light application fifteen to twenty minutes in well-vascularized, and, for a shorter time, in cicatricial tissue. While his experiments are still too limited to permit of extensive generalizations, they seem to indicate a possibly valuable therapeutic aid in the use of the light rays against microbic infection. The method is so easily put into practice that its usefulness, if it proves as great as seems to be indicated by this communication, will add greatly to the effectiveness of the Finsen method. It would be interesting to test the effect of the *x*-rays on similarly sensitized germs. Dreyer's communication ends with a request to his colleagues to report to him their experiences with this method.

### A SOLUTION OF THE RACE PROBLEM.

A Philadelphia professor, it is reported, recently called attention to the fact that in his experience the skin of the negro becomes white under the influence of *x*-rays. We have not mastered the question of the origin of pigmentation in the human or other species, and are, therefore, not surprised at any such development. It would be interesting to know how further experiments in this line will result. An ambitious New Jersey physician, it is said, is taking negro babies at birth, and by the use of the light treatment hopes to be able to affect their future color. We anxiously await the outcome of the attempt on the part of science to solve the race problem.

### A RESULT OF CLUB PRACTICE.

The abuses of club practice are rather emphatically shown by a communication in the *British Medical Journal,* January 16, signed "One of the Crushed Doctors." In the community in which the correspondent lives, we are told that a medical man can not even afford a horse, much less leave his practice for a holiday. The amount of medical and surgical work he has to do for nothing is appalling, and if he airs his grievances to the workingman he becomes a monster in that man's sight. Educated people respect the doctor and consider him a gentleman, but the working class, which makes up the larger portion, gives an ignorant nod and familiarly calls the doctor "Jones" or "Smith." If ones tries to collect his bills in court, he receives only the sneers of the crowd and the gibes of the judge for his time, worry, anxiety and loss of sleep, and he has spent 20 shillings to collect 15. He says his experience in this respect has been so bitter that, unless paid at once, he never keeps count of the items, and is happier and better off. The only remedy this crushed doctor sees is in organization in the profession. Physicians must stand together and make their power felt. He says the good money, the easy and spare time, the privileges, the voting power, "the jaunting about, the spending of valuable time and money in betting, gambling, and public houses, the eating and stuffing, the gaudy and expensive dressing, together with the throwing of wholesome food to the rubbish heap," belong to the workingman, not to the doctor in his community. Altogether, it would seem that this "crushed doctor" must be living in a pretty hard community. We have not the evil of club practice in this country to the extent that this contributor indicates, but we may have it if we are not more watchful than we are at present. There are thousands of physicians in this country who are *working for an income less than that which the* average skilled laborer now receives, and with little prospect of improvement. Shall we permit ourselves to fix this condition for a still larger number of our profession by passively permitting club practice to be established among us?

### PHYSICIANS AS DETECTIVES FOR THE POLICE.

In Birmingham, England, the members of the medical profession have taken considerable exception to a circular sent out by the chief constable of that city, calling attention to the murder of a new-born child, and asking information from any physician who had attended a woman who might have been the mother. The physicians object to being made detectives. In the London *Lancet* we note the Birmingham coroner's statement as follows:

> There is a common law liability—a liability that is not specifically set down by act of parliament—under which it becomes the duty of a man, doctors included, to inform the authorities if he believes that a crime has been committed. But, of course, he can always please himself whether or not he does inform them. If he does not, then you have to prove that he has wilfully disregarded his obligation, and that, I can imagine, would not always be an easy matter.

In this connection it is of interest to note that a similar discussion has been taking place recently in this country as the result of the situation in which a certain physician found himself, and concerning which he asked for advice. He was morally certain that a new-born, illegitimate child—at whose birth he officiated—had been strangled, and he was at a loss whether he should inform the authorities, and whether, if he did not inform them, he would be a party to the crime. The opinions expressed were varied, some urging the physician's responsibility to the law and saying that he should not allow crime to go unpunished; others saying that he had no right to violate the confidence that a patient had shown in him by calling him in such a case. Attention was called to the physician's duty to the community. Without discussing the broad subject of privileged communication, perhaps it is fair to say that the physician's attitude should be this: There is no conflict between the law as regards the concealment of crime, on the one hand, and the duty to the patient, on the other. The physician is not a detective; therefore, he should preserve the confidence of his patient while there is any doubt as to a murder, but if he is certain that he has a murderer for a patient the officers of the law should be informed.

### THE CAUSE OF EPILEPTIC CONVULSIONS.

Various theories have been advanced to explain the occurrence of an epileptic seizure, but none of these is entirely satisfactory. It has been supposed that there is a slight chemical change in the gray matter of the cerebral cortex, rendering it very unstable. If, now, the gray matter holds in store a large amount of nerve energy, an epileptic fit may be caused by a sudden and violent discharge of this nerve energy, either with or without a stimulus. Another recent theory is that advanced by Krainski. He found that the output of urea is greatly diminished for a day or more before the occurrence of a fit. In this disturbed metabolism the system is supposed to form ammonium carbonate instead of urea. This compound gives off ammonia, and Krainski believes that the epileptic fits are caused by the ammonia, but this view is contradicted by other authorities. We are, therefore, still very much in the dark concerning the nature of this disease, but it seems that much new light may be thrown on it by experiments. This has recently been attempted, and the results reported are both interesting and encouraging. Mott and Halliburton showed several years ago that the blood, and especially the cerebrospinal fluid of patients suffering from degenerative diseases of the central nervous system, such as epilepsy, combined sclerosis, disseminated sclerosis, etc., contain considerable quantities of cholin ($C_5H_{15}NO_2$). This substance, which is of the nature of an alkaloid, is believed to be split off from lecithin, which in turn is derived from the medullary sheath of the nerve fibers during the process of degeneration. Donath[1] has repeated and verified Mott and Halliburton's observation and came to the conclusion that cholin may be responsible for the convulsions of epilepsy. He examined for cholin the cerebrospinal fluid of 18 cases of idiopathic epilepsy, with 15 positive results; of 3 cases of Jacksonian epilepsy, with 3 positive results, and of many cases of locomotor ataxia, paralytic dementia, brain syphilis and brain tumor, with positive results in nearly 90 per cent. of the cases. By injecting a solution of cholin into the cerebral cortex of animals he was able to produce both localized and general convulsions, which sometimes ended in paresis of groups of muscles. No such convulsions were caused by the injection of salt solution of various concentrations. It would seem, therefore, that epilepsy may be a kind of auto-intoxication, and that the convulsions are caused by a definite chemical substance which is formed in the central nervous system by the degeneration of some of the nerve elements.

## DANGEROUS WOOD ALCOHOL.

The dangers of wood alcohol have been pointed out for several years, but the public seems to have but little knowledge of them. Four negroes died in Chicago a few days ago from drinking wood alcohol which was sold to them under the general name of alcohol. We know of no such wholesale instance of methyl alcohol poisoning before, but it furnishes a striking example of the perils that exist in its substitution in various agencies which are made up for dietetic and other purposes. These colored men were topers in the last degree, drinking their material pure, each probably taking a considerable quantity, though the amount is not stated in the accounts. The material was furnished by a druggist, who, it seems, ought to be liable under both the state and Federal laws for thus retailing alcohol for drinking purposes. If alcohol is allowed to be sold to anyone it is important that it should be the genuine article and not this poisonous form. The use of wood alcohol is extending in various ways, and it is extremely important that its dangers should be recognized by the laity.

## THE PHYSICIAN IN POLITICS.

Our brothers in the medical profession in Colorado are evidently alive to the needs of medical reform in that state and are equally wideawake as to the means of bringing it about. Beside a complete state organization in connection with the Committee on National Legislation of the American Medical Association, with representatives in every county, they have also organized a Colorado Medical Legislation League to secure "the improvement and enforcement of the medical laws of the State of Colorado." This body is non-sectarian, and aims to include all reputable legally qualified physicians who are interested in medical reform and who will devote some of their activities and influence to this end. It is proposed to confront each candidate for office with the question whether he favors or opposes medical reforms. In this way physicians can make their influence felt by politicians who will not dare to disregard the wishes of so influential a body as a united medical profession. The need of such a movement in Colorado is obvious, as in that state the quacks have of late years seemed to have exclusive access to the executive ears, ample as they evidently must have been. If the profession insistently so will it, Colorado can, with the next election, have a governor who will intelligently fill his high office and not annul wholesome medical legislation by vetoes inspired by frauds. With this special education of candidates the league will also carry on a general campaign of education, correcting the erroneous statements that may be given out in the public press and otherwise, and generally educating the public as to the true purposes of the organization. The example is a good one, and it would be well if similar efforts were made in every state.

## THE COST OF PRODUCTION OF DIPHTHERIA ANTITOXIN.

So many statements have been made in the public press during the last few weeks regarding the cost of producing diphtheria antitoxin that it is interesting to turn to the itemized statement published by the State Board of Health of Massachusetts in the thirty-fourth annual report which has just reached us. It appears from this that the expenditures at the pathologic laboratory at Forest Hills, where the diphtheria antitoxin is prepared under the direction of Prof. Theobald Smith, amounted during the year ending Sept. 30, 1902, to $6,562.14. This includes the salaries of assistants and attendants. the purchase of animals, the board of the horses, and the apparatus, chemicals and laboratory supplies, together with a variety of incidental expenses. During the year ending March 31, 1902, 40,211 bottles, and in the year ending March 31, 1903, 33,475 bottles were issued, each bottle containing 1,500 units. This would amount to an average production of 55,264,500 units annually. It is to be presumed that the salary of the director, as well as the expense of distribution, together with depreciation and interest charges on the plant, are not included in the figure given above, which, we understand, is simply the running expense account. As a partial offset to this, however, it may be mentioned that certain examinations of diphtheritic and tuberculous material are made at the Forest Hills laboratory, the cost of which is apparently not separated from that of the antitoxin production. Assuming that the whole amount legitimately chargeable to the cost of producing diphtheria antitoxin was not more than $15,000, which, considering the items included in the statement cited, seem a very liberal estimate, the cost per 1,000 units would not be more than 28 cents. In view of the figures printed in The Journal, January 23, this would seem to indicate that the price of $1.33 per 1,000 units recently established by the manufacturers, affords a margin larger than would be deemed absolutely necessary to the profitable and successful conduct of ordinary commercial undertakings.

---

## Medical News.

### ALABAMA.

**Will Enforce Law.**—Twelve physicians have been appointed by Dr. Charles Whelan, Jr., city physician of Birmingham, to carry out the law, which provides that all persons shall be vaccinated who can not show signs of successful vaccination during the last seven years.

**Personal.**—Dr. Claude L. Murphee, Gadsden, has been elected health officer of Etowah County.——Dr. George A. Ketchum has been re-elected chairman, and Dr. Vivian P. Gaines, secretary, of the board of censors, of the Mobile Board of Health.——Dr. Ulysses G. Mason has resigned as assistant city physician of Birmingham.

**Smallpox.**—All public gatherings at Sheffield have been prohibited in Sheffield, which has at present 15 cases.——Florence has quarantined against Sheffield.——Altoona has 4 cases.——Jefferson County Medical Society, on account of the prevalence of smallpox in the county, urges compulsory vaccination.——Cordova is rumored to have about 250 cases.——Several cases have developed in Tuscumbia, and compulsory vaccination of all school children has been ordered.

### COLORADO.

**Jury Disagreed.**—In the suit brought by Edward O'Donnell against Dr. Daniel R. Lucy, Denver, for alleged malpractice, in which the plaintiff claimed $10,000 damages, the jury failed to agree, and was discharged.

**December Deaths.**—During December 800 deaths were reported in the state, equivalent to an annual mortality of 16.38 per 1,000. Of these 23 were due to typhoid fever, 20 to diphtheria, and 16 to scarlet fever.

**Typhoid Epidemic in Leadville.**—Leadville has had about 500 cases of typhoid fever; the State Board of Health has cooperated with the local authorities, and it is now believed that the situation is well in hand. The chief work now being done is in the direction of tracing the infection to its source.

**Communicable Diseases.**—There were reported to the State Board of Health, during December, 200 cases of scarlet fever, 121 cases of diphtheria, 100 cases of smallpox and 77 cases of typhoid fever. Compared with the previous month this shows an increase of 21 cases of diphtheria, 49 cases of scarlet fever, and 40 cases of smallpox, and a decrease of 244 cases of typhoid fever.

**Boulder County Medical Society.**—This society held its annual meeting in Boulder, January 7, and elected the following officers: President, Dr. Walter W. Reed; vice-president, Dr. William J. Baird; secretary, Dr. Oscar M. Gilbert; treasurer, Dr. Martin E. Miles; censors, Drs. George H. Cattermole, Horace O. Dodge, and William J. Baird, and delegate to state society, Dr. George H. Cattermole, all of Boulder.

### CONNECTICUT.

**Infectious Diseases.**—Two cases of smallpox were reported during December, 1,722 cases of measles, 184 cases of scarlet fever, 152 cases of diphtheria, 55 cases of whooping cough, 65 cases of typhoid fever, and 22 cases of consumption.

**Unlicensed Practitioners Fined.**—J. Lewis Sweet, Milford, and Eugene J. Higgins, New Haven, charged with prescribing drugs for pay without a physician's license from the state, were each fined $100 and costs, the minimum sentence under the law.

**December Mortality.**—During December there were 1,322 deaths in the state, equivalent to an annual mortality rate of 17 per 1,000. There were 151 more deaths than in the month preceding, 24 more than in December, 1902, and 128 more than the average for December of the last 5 years. Infectious diseases caused 18.3 per cent. of the mortality.

**Temperance, Physiology and Hygiene.**—The Connecticut State Board of Education has sent out a pamphlet to teachers, with suggestions as to teaching temperance, physiology and hygiene. The objections advanced to alcohol as a drink are that it injures the cells of the body, weakens the muscles, harms mind and morals, decreases resistance power, predisposes to disease, and tobacco is arraigned because it retards growth, dulls intellectual power, may produce serious nervous disturbances, and interfere with digestion and predisposes to diseases of the throat and heart.

### ILLINOIS.

**Personal.**—Dr. Llewellyn B. Ashton, assistant surgeon at the Soldiers' Home, Quincy, has resigned.——Dr. Martin Cushing has been appointed local surgeon of the Chicago and Alton Railway at Joliet, vice Dr. James A. Clyne.

**Normal and Not Bloomington Has Smallpox.**—An item in The Journal of last week was incorrect in that it stated that schools and churches in Bloomington were closed indefinitely on account of smallpox. Normal, which adjoins Bloomington, is the infected town, and Bloomington has at present only one case of smallpox.

**Eminent Chemist Dead.**—Prof. Arthur W. Palmer, head of the department of chemistry in the University of Illinois, Champaign, who had made a national reputation by his research work for the last nine years on the Illinois water survey, died at his home in Champaign, February 3, after a short illness, aged 33.

**Prevention and Suppression of Typhoid.**—The Illinois State Board of Health has prepared rules and regulations concerning the prevention and suppression of typhoid fever. These were formally adopted by the board at the annual meeting. Copies of these rules have been sent to all newspapers in the state and to every county, township, village and city health officer, and they will also be distributed among the people by the local health officers.

### Chicago.

**Personal.**—Dr. Ludvig Hektoen is expected to deliver an address before the Minneapolis Pathological Society February 15. The Hennepin County Medical Society and the Minneapolis Medical Club have been invited to be present.

**Addition to Hospital.**—The directors and medical board of Presbyterian Hospital have under consideration plans for the construction of additions to the institution, including a surgical pavilion and a new out-patient dispensary for the poor. Part of the $500,000 required for these additions has already been pledged.

**January Deaths.**—The total deaths for the month were 2,361, or an annual rate of 1,424 per 1,000. In January, 1903, 2,573 died, and in December, 1903, 2,354. The principal death-causes were pneumonia, 504; consumption, 248; heart diseases, 205; Bright's disease, 156; violence, 141 (not including deaths from Iroquois Theater fire), and bronchitis, 123.

**Deaths of the Week.**—The total deaths for the week ended February 6 were 596, equivalent to an annual death-rate of 15.92 per 1,000; exactly the same number as in the corresponding week of 1903. Pneumonia still maintains its lead with 151, consumption following with 54, and Bright's disease and heart disease coming next with 48 and 45 respectively.

**Popular Lectures.**—Under the auspices of the School of Domestic Arts and Sciences, the following arrangements for lectures have been made: Dr. Walter S. Christopher, "Care and Diet of Children"; Dr. John B. Murphy, "The Significance of Timely Action in Acute Surgical Diseases"; Dr. Harry B. Favill, "Food Requirements"; Dr. E. Fletcher Ingals, "Colds," and Dr. James B. Herrick, "Self-Limitations of Certain Diseases."

**The Pasteur Institute's Work.**—Dr. Antonio Lagorio, director of the Pasteur Institute, reports that since the institute was opened, July 2, 1890, 2,026 patients have received the antihydrophobic treatment. Of these 1,807 had been bitten by dogs, 76 by horses, 57 by cats, 19 by cows, 18 by skunks, 25 by other animals, and 22 were infected by hydrophobic human beings. Of individuals bitten by animals absolutely known to have been rabid, 982 were treated; of patients bitten by animals presumed to have been rabid because of symptoms of disease during life, 776 were treated, while 268 cases were cared for in which rabies was suspected. Only 7 deaths are reported. a mortality of 0.34 per cent. Six individuals abandoned treatment, 2 of whom subsequently died from hydrophobia.

## INDIANA.

**Hospital Opens.**—The Flower Mission Hospital for Incurables, Indianapolis, was opened for patients, January 27.

**Nurses Meet.**—A meeting of the Indiana State Nurses' Association will be held at the Grand Hotel, Indianapolis, February 22.

**All Physicians Members.**—The Vanderburg County Medical Society held its regular meeting, January 10, at the offices of Drs. Walker Welborn, Evansville, it being the tenth anniversary of the opening of the Evansville Sanitarium. This society, three years ago, took into its membership all sectarians, and now practically every physician in the county is on its roll. The result has been entirely satisfactory. Evansville was the first city to take so sweeping an action.

**Vital Statistics of Indianapolis.**—During January, 1,004 cases of measles were reported. In January, 1903, 261 cases of smallpox were reported, and only 2 in January, 1904. Typhoid fever had 50 victims in January, 1903, and only 7 cases in January of this year. A similar reduction was observed as regarded diphtheria and scarlet fever. During 1903, 3,004 deaths occurred, a death-rate of 15.02 per 1,000. Tuberculosis caused 353 deaths; pneumonia, 185; smallpox, 96; typhoid fever, 93, and diphtheria, 35.

**Sickness and Death in December.**—Measles was reported from all parts of the state in December. There were 9 deaths, and at least 10,000 cases. Tonsillitis was second in prevalence, many of the cases, no doubt, being diphtheria. Pneumonia was third in prevalence, then rheumatism, bronchitis, influenza, smallpox, scarlet fever, typhoid fever, diphtheria and diarrhea in the order named. Of smallpox 523 cases, with 2 deaths, were reported. In the corresponding month of last year 642 cases were reported, with 17 deaths. Almost one-half of the cases were reported from Clay County. The first marked epidemic of smallpox occurred in that county four years ago, and despite many deaths and a great number of severe cases, it has been impossible to secure general vaccination. The deaths from tuberculosis numbered 371, a rate of 173.9 per 100,000. In the same month of 1902, the deaths numbered 319, rate 149.5. Typhoid fever caused 65 deaths. In the same month last year 91 deaths were reported. There were 701 cases in all. Pneumonia caused 392 deaths, a rate of 183.8 per 100,000. In the same month last year 267 deaths were reported, a rate of 125.1. By other causes than the above, the deaths were: diphtheria, 54; scarlet fever, 34; diarrheal diseases, 23; cerebrospinal meningitis, 34; influenza, 35; puerperal fever, 10; cancer, 91, and violence 153.

## MARYLAND.

**Diphtheria and Smallpox.**—Seven cases of diphtheria have occurred in one family in Baltimore County.——The smallpox situation in Garret County was said to be improving January 31.

**Want General Hospital.**—A public meeting was held at Hagerstown, February 2, for the establishment of a general hospital there for Washington County. The movement originated with the county medical society. A committee was appointed to get charter and necessary legislation, including an appropriation from the legislature.

### Baltimore.

**Vital Statistics Fees.**—An ordinance proposed in the city council for paying physicians $1 for registering deaths and births has been indefinitely postponed.

**Personal.**—Dr. Nathaniel G. Keirle, Jr., has returned from Paris. He will take charge of the laboratory of the Pasteur Institute of the College of Physicians and Surgeons.

**Crusade Against Spitting.**—One effect of the Tuberculosis Exposition is that the city health department has started a crusade against spitting in street cars, public buildings, etc. Much comment has been caused by the refusal of a magistrate to enforce the law on the subject.

**January Disease and Death.**—The report for January shows 959 deaths and 674 births. The health department has not succeeded in having all the latter reported as yet, whereas no one can be buried without a permit. Diphtheria, tuberculosis, scarlet fever and typhoid were more prevalent than last year, while influenza and pneumonia showed a much reduced mortality and measles was not represented.

**The Baltimore Fire.**—The great fire of Feb. 7 and 8, 1904, which burned over twenty-four squares of the business center of Baltimore, entailing a loss of over $100,000,000, but which was marked by exceedingly few fatalities, burned the office of the State Board of Health. The offices of the *Maryland Medical Journal* escaped, as did Johns Hopkins Medical School and Hospital, although the latter were within a few blocks of the fire.

**Tuberculosis Exposition Closed.**—The Tuberculosis Exposition closed February 1. The legislature was invited to inspect it on that day, but only two members came. Dr. William Osler gave an address at 10 a. m. on the "Literature of Tuberculosis," using the collection which had been made for the exposition. The disease has always been known, but Hippocrates confounded it with other affections causing extreme emaciation. He made five periods of the history of tuberculosis: 1, from Hippocrates to seventeenth century, Morton of England and Sylvius of Holland; 2, from the latter to 1810, Bedard; 3, from the last to 1819, Laennec; 4, from Laennec to 1882, Koch, and 5, since Koch. A great crowd attended this final lecture of the series.

**Dispensary Report.**—The Northeastern Dispensary makes the following report for 1903: New patients, 7,250; total visits, 15,798; visits in general medicine, 5,853; in eye department, 2,353; in ear department, 294; in gynecological department, 1,050; in surgical department, 1,714; in children's department, 3,534; in skin department, 892; in dental department, 710; in obstetrical department, 13; operations in eye department, 221; operations in ear department, 85; operations in nose and throat department, 10; operations in surgical department, 117; operations in gynecological department, 543; patients visited at their homes, 230; visits made to the homes, 1,032; prescriptions filled in dispensary, 21,385; prescriptions filled for outside physicians, 905. Dr. Arthur Wegefarth was re-elected president of the board and Dr. Alexander D. McConachie, secretary. The following changes in the staff were made: Dr. Louise Erich was placed in charge of the orthopedic department; Dr. Ernest Lehnert was made assistant in surgery and gynecology; Dr. A. G. Singewald was appointed to the children's department, and Dr. P. E. Lilly was made chief of the outdoor clinic.

## MASSACHUSETTS.

**Senate Refuses Antitoxin Grant.**—The senate has refused to grant to the State Board of Health the $1,500 necessary to produce the antitoxin and vaccine virus which they are directed by last year's legislation to furnish free to the physicians of the state.

**Object to Removal of Ice by Salt.**—The Boston Board of Health has warned people, especially the street railway employes, that salt must not be used so freely in getting rid of ice and snow. Much complaint has arisen because pedestrians have been obliged so often to wade in a freezing mixture of snow, water and salt, resulting in serious risk to health.

**Would Abolish Unpaid Commissioners.**—Out of the investigation of pauper institutions at Long Island last summer, when the board of unpaid commissioners was criticised because the City Chronic Hospital was so well conducted, has come a bill to the legislature, abolishing the board and substituting one paid commissioner. The bill was approved by Mayor Collins' legal representative, and is not likely to be favorably reported.

**Newton Hospital Report.**—The reports presented at the annual meeting of the Newton Hospital Corporation showed assets of $216,079; endowment, $74,087; contributions from the churches of the city, $10,805, and earnings, $24,485, an increase of $2,000 over 1902. Current expenses were $36,049, $2,500 less than in 1902; 814 patients received treatment, the average cost in the wards being $14.00 per week, and in the contagious wards, $20.00 per week. A new maternity ward is urgently needed. The vote abolishing the office of superintendent virtually removed Dr. Francis G. Curtis, who for six years has served without pay. Dr. J. R. Phelps, Malden, is the newly elected house officer in charge.

## NEW YORK.

### New York City.

**Munificent Gifts.**—Miss Emily A. Watson has given $100,000 to the New York Orthopedic Dispensary and Hospital, to establish a branch of the institution at White Plains; she has also agreed to endow this branch with a fund of $250,000.

**Midwives Prescribed.**—Five of the six midwives in the Bronx charged with practicing medicine without a license pleaded guilty, January 25, and were each fined $50. The New York County Medical Society preferred charges in these cases.

**Norwegian Hospital Open.**—The new Norwegian Hospital, Brooklyn, is almost ready to receive patients. It was opened, February 1, with a fair, which continued all the week. The institution will accommodate 100 patients and will represent an outlay of about $150,000.

**Attendants Exonerated.**—The charges brought against certain nurses in the Manhattan State Hospital, Ward's Island, by Miss Ellen Isibel Farley, after having been thoroughly investigated by the State Commission in Lunacy, have been declared without foundation, and have been dismissed.

## OHIO.

**Osteopath Fined for Not Reporting Diphtheria.**—Joseph A. Vance, president of the Ohio College of Osteopathy, Chillicothe, was fined $20 and costs, February 2, for failing to report a case of diphtheria to the proper health officials.

**Typhoid in Columbus.**—During January 723 cases of typhoid fever were reported in Columbus, with 23 deaths. On January 31 the highest record of new cases was made, with 81. The mayor has appointed a joint commission from the local board of health, a committee from the Columbus Academy of Medicine, and the sanitary committee of the board of trade, to investigate and report on the causes of the epidemic.

**Vital Statistics of Dayton.**—The report of the board of health for the year 1903 shows a total of 1,928 births, or 20.29 per 1,000 of population. At least one birth in ten, it is thought, was not reported. The number of deaths for the same period was 1,198, or 1,261 per 1,000 of population. The report also shows that 110 cases of smallpox developed in the city during 1903, costing an average of $136 per patient. The department vaccinated 6,500 free of charge, and this wholesale vaccination put an end to the epidemic.

### Cincinnati.

**District Physicians.**—Dr. J. W. Hall has been appointed district physician to the eighth ward, vice Dr. C. W. Dane, resigned, and Dr. Frank C. King, in the fourth ward, vice Dr. J. T. McKibben, resigned.

**Christ's Hospital Reopened.**—Christ's Hospital, closed for repairs July 1, 1903, was reopened to patients February 1. The repairs practically amounted to a remodeling, and have cost more than $60,000. The hospital now has accommodations for 100 patients, and in addition there is an outside building which will accommodate about 45 deaconess nurses.

**Peculiar Situation at Hospital.**—A peculiar condition of affairs exists at the Cincinnati Hospital. The annual appropriation has been so small and the number of patients so large that gradually the hospital has been getting deeper into debt, until now it owes about $30,000. The hospital now contains 120 more patients than it really has room for, and they are sleeping in the end-rooms, on the floor and wherever an additional cot can be squeezed in. The reason of this overcrowding is the measles and typhoid epidemics, and to this fact the attention of the board of public service has recently been called. According to the law, the $50,000 bond issue asked for can be allowed only by an election, which would cost the city $20,000, or it must be shown that there is some extraordinary need, as, for instance, an epidemic. The medical directors of the Cincinnati Hospital then reported to the board of public service that there is an epidemic both of measles and typhoid fever in the city. Following this advice the board immediately authorized a $50,000 bond issue for emergency hospital purposes. Before the bonds can be issued, however, the ruling must pass the council, but no difficulty is anticipated here, as press and public are heartily in favor of the movement.

## TENNESSEE.

**Anti-Vaccinationists Arraigned.**—The health officer of Knoxville has sworn out 18 warrants for individuals who have refused to be vaccinated as prescribed by the city ordinance.

**Smallpox.**—Lowerville reports 7 cases, with no deaths.——Several prisoners in the Jacksboro jail are suffering from smallpox, and the jail is under strict quarantine.——On February 1 there were 280 people in the Knoxville detention camp and isolation hospital. The situation has greatly improved.

**Dr. Happel's Illness Not Severe.**—It was reported that Dr. T. J. Happel, Trenton, had suffered a stroke of apoplexy. We are happy to state that the only foundation for the rumors was the fact that, while eating, Dr. Happel suffered from a spasm of the glottis, followed by fainting. He recovered in an hour.

## GENERAL.

**The Ingersoll Lecture** at Harvard University this year will be given by Dr. William Osler, on "Science and Immortality."

**The Association of American Universities**, at its meeting at Yale, February 18-20, will discuss the actual and the proper lines of distinction between college and university work, uniformity of university work, the administration of publications and their circulation, and whether the bachelor degrees in science and letters are to be preserved or are to be merged in the degree of bachelor of arts.

**Examinations for Army Medical Service.**—The examination of applicants for appointment as assistant surgeon in the United States Army will be resumed in Washington immediately after the close of the present session of the Army Medical School; it will embrace the full examination (as heretofore), at the conclusion of which those found qualified will be commissioned. Full information as to the requisite qualifications, nature of examination, etc., may be obtained from the Surgeon-General of the U. S. Army, Washington, D. C. The examining board will probably reassemble about the middle of April, and applicants should make application at once. Applicants are restricted in age to thirty years, and one year's hospital experience or its equivalent in private practice is required.

## CANADA.

**Protestant Hospital for Insane, Quebec.**—At the annual meeting in Montreal last week, voluntary commitment was discussed; the medical superintendent, Dr. Burgess, had been solicited by people who believed they would be mentally benefited by treatment in the institution. The law forbids this form of commitment. The matter will be brought to the attention of the provincial government. The admissions for 1903 were 152; number under treatment, 581; discharged as recovered, 57; as improved, 23; deaths, 44.

**Ontario Teachers To Be Trained in Hygiene.**—A medical conference was held last week in Toronto, as the first step in an investigation of school hygiene by the Ontario Board of Health. One result of the conference may be a medical section in connection with the annual conference of the Ontario Teachers' Association. Papers were read on the prevention of infectious diseases, and Dr. C. A. Hodgetts, secretary of the Ontario Board of Health, advocated compulsory drill for school boys, as the basis for men trained for the militia.

**Personal.**—Dr. A. J. Richer, secretary of the Montreal League for the Prevention and Cure of Tuberculosis, has returned from a four weeks' visit to the United States, where he studied tuberculosis organizations and methods.——Dr. A. D. Decelles, general librarian of the parliamentary library at Ottawa, who was created by the government of France a chevalier of the Legon of Honor last October, for his work in connection with literature, was presented by his friends with a beautifully wrought address and a massive silver inkstand, last week, the presentation being made by Dr. Prevost of Ottawa.

**Unusual Mortality in Toronto in January.**—For the first time in the history of the city, so far as the records show, deaths for January numbered 412, an excess of seventy over January, 1903. Sixty-five cases of pneumonia died, and 178 persons died who were over 50 years of age. Of these six were over 90 years, 31 over 80, 39 over 70, 61 over 60 and 41 over 50. There were 26 deaths from tuberculosis and 21 from diphtheria. During the month there were 415 births. The city was remarkably immune from typhoid fever, only 2 cases being reported. This showing indicates the purity of Toronto's water supply; it has been asserted that it is the purest in America.

## FOREIGN.

**Liverpool University's new chair in dermatology** is the gift of Dr. Stopford Taylor.

**Tenth Quadrennial Congress of Polish Physicians and Scientists.**—This will be held in Lemberg, Austria, July 20-24,

1904. Dr. Francis E. Fronczak, 508 Fillmore Avenue, Buffalo, N. Y., is the United States representative of the committee of arrangements.

**Isolation of Consumptives in Hospitals.**—The Paris Société des Hôpitaux recently voted a resolution urging the authorities to insist on the isolation of all cases of "open tuberculosis." In order to have it attended to at once they advocate placing in the general wards in the hospitals glass partitions to wall off a certain part of the ward to be allotted to this class of patients entirely. This will reduce the danger of contagion for the other patients, while not adding to the tasks of the attendants or increasing the difficulty of supervision of the ward.

## DUBLIN LETTER.

### Deaths in the Profession of Dublin.

During the past year death dealt unusually harshly with the medical profession in Dublin. Only a few months ago two colleagues at the Royal City of Dublin Hospital, Sir George Duffey and Mr. H. G. Croly, past presidents of the royal colleges of physicians and surgeons, respectively, passed away within a few weeks of each other. On Christmas day a veteran of Dublin practice followed them, Dr. C. F. Moore, who had been for many years certifying surgeon under the factory acts, and had nearly reached his ninetieth year. With the new year Trinity College lost two distinguished graduates —one of her oldest and one of her youngest in the service of the king. Sir William Kynsey had entered the Army Medical Service in 1863, and after serving in the Ashantee war was appointed to an important government post in Ceylon, which he held till a few years ago. Lieut. Joseph Welland had entered the Royal Army Medical Corps in 1900, and now in his second campaign in Somaliland has been speared in battle while in discharge of his duty. As a Dublin student he was a well-known oarsman, and some of your readers will learn with regretful interest that he stroked the Dublin crew in the famous contest with the Pennsylvania crew at Killarney in 1901.

### The Poor Law Medical Service.

The one subject of interest to the profession in Ireland at present is the position of the medical officer in the Poor Law Medical Service. Though to all Irishmen, at home or abroad, the "dispensary doctor" is as familiar a figure as the parish priest, and his position as well defined, yet it may be well, in a few words, to explain his position and duties. It is the custom for the local elective boards, the boards of guardians, to appoint in each district throughout the whole country, a medical man whose duty it is, at a fixed salary, to attend all the poor of the district. There is no definition of "poor person," and to be entitled to free medical treatment, all that is necessary is the possession of a ticket signed by a member of the board of guardians. When it is remembered that many of the guardians are small shopkeepers and village publicans, it is obvious that abuse of the issue of tickets is easy. In pursuance of his duty the dispensary physician has to attend on fixed days, two, three, or more in the week, at appointed stations in his district and give the necessary treatment to those who present themselves. In addition, he has to hold himself in readiness to attend patients at his own house at any time, and should he receive a "visiting ticket" he must at once, whether by day or night, proceed to visit the patient. He is not allowed to leave his district, even for an hour, without permission from the guardians. The salaries paid to the medical officers vary from £30 to about £150 a year (about $150 to $750), but, of course, private practice is allowed, so long as it does not interfere with public duties. The districts vary greatly in size, some being only four or five miles in diameter, and others up to thirty or forty. In many parts of the country almost the whole population come under the title of "poor persons," and obtain gratuitous medical relief, it not being an unusual thing for a guardian to issue tickets to his own immediate relatives. It will be easily seen that under such circumstances the emoluments from private practice are inconsiderable. Under the most favorable conditions, except in some of the more prosperous country towns, the position of the dispensary physician is an unenviable one. He is the servant of a board composed of men who are for the most part his inferiors in education and social position. He has no time of leisure; night and day he is at the beck and call of the public. His salary is small, and out of it he must keep one or two horses and a trap. In addition to his strictly medical duties, he is in nearly every case his own dispenser. He has no right to any annual holiday, and if with difficulty he obtains it, he usually has to pay his substitute, at least in part. There is no satisfactory arrangement for superannuation, and after forty years' service, when old age and ill health make retirement a necessity, a pension may be refused. Again, the election of the medical officer being in the hands of a popular and often ignorant board, who are quite incapable of judging the qualifications or professional merits of the candidates, the appointment is made on other grounds than desert. Family influence, religious and political considerations carry the day. In some cases, indeed, the advertisement for a medical office demands that he must be a member of a certain political organization. At the present time firm stand is being made by the profession in Ireland, and the Irish Medical Association, the strongest representative body of medical men in the country, has adopted a certain program of what it considers the minimum of necessary reform. The points insisted on are, in brief, higher salaries, with a minimum of £200 a year, a monthly holiday of four weeks, and proper pension arrangements. Many of the more ardent reformers, however, go much further, and, in particular, Dr. Kidd of Enniskillen urges that the whole medical work of the poor law service should pass into the hands of the state, to be managed on lines similar to the navy and army medical services. Other medical men differ widely on this point, and quite recently Dr. McArdle, a well-known surgeon in Dublin, has had a tilt at Dr. Kidd in the daily press. There are present many dispensary appointments vacant all over the country, it being impossible to attract candidates at the salaries offered.

### The Tuberculosis Prophylaxis Campaign.

The most serious problem of public health in Ireland at present is the question of tuberculosis. While in England and Scotland during the last forty years the death rate from tubercular diseases has diminished by nearly a half, the rate in Ireland is practically stationary. This, in itself, is very discouraging, but when it is remembered that the population in Ireland is mainly agricultural, and in England industrial, it is even worse, since the agricultural life is certainly the more hygienic. Vigorous attempts are being made on all sides to instruct the people in the proper measures to adopt to prevent tuberculosis, and the Roman Catholic priesthood has taken the matter up very warmly, and the bishops have arranged for lectures in hygiene to be given at the College at Maynooth. The National Board of Education, in like manner, is giving instruction to the primary teachers, whose influence reaches very far. The present accommodation in Dublin for the treatment of consumption is still far from adequate. Institutions of two kinds are needed, for the isolation and care of incurable patients, and for the treatment and cure of early cases. There are, of course, institutions of both kinds doing excellent work as far as their resources allow, but they are on too small a scale and hampered by lack of funds. The danger to the public from tuberculosis is of the gravest nature, and demands public action of a comprehensive kind.

A case of typhoid fever, very interesting on the pathologic side, has just been published by Dr. H. C. Drury, a Dublin physician. The patient, a young man of 21, recovered from an attack of typhoid, perforation having taken place and operation performed in consequence. Twenty-one days after the temperature had become normal acute obstruction of the bowels occurred, and, in spite of operation, the patient died. The obstruction was due to extensive peritoneal adhesions, but the state of the interior of the bowel was the most interesting point. Here was found an enormous number of ulcers still unhealed, three weeks after the temperature was normal, during a fortnight of which time solid food was being given.

## LONDON LETTER.

### The Profession in 1904.

The Medical Directory for 1904 shows that there are 37,730 registered practitioners—an increase of 439 on the number for 1903. It is satisfactory to chronicle that in the overcrowded state of the profession the annual addition tends to decrease. Thus in 1894 the addition was 1,013; in 1895, 818; in 1896, 730; in 1898, 713; in 1899, 619; in 1900, 534, and in 1903, 503.

### Royal Army Medical College and Hospital.

A new military hospital has for some years been building on the Thames Embankment, and is now nearly complete. It will be the military hospital for the London garrison. There will be 225 beds, of which 150 will be assigned for ordinary purposes, excluding venereal diseases, and 75 will be reserved in clinical wards for special cases. The professors of military surgery and tropical medicine of the Royal Army Medical College will be in charge of the surgical and medical divisions respectively, and will give clinical instruction to the medical officers attending the college. They will be assisted by officers who will perform duties similar to those of house officers in civil hospitals. Near the hospital will be built the Royal Army Medical College, which will contain class rooms and laboratory accommodation for pathology and bacteriology. These arrangements are part of the outcome of the radical reform of the army medical department, which resulted from the sensation produced by the so-called "hospital scandals" of the Boer War.

### State Registration of Trained Nurses.

The Royal British Nurses' Association is promoting a bill for the state registration of trained nurses. A central board is proposed of physicians and nurses appointed by medical and nursing organizations. At first two years' training in an institution recognized by the central board will be required, later three years' training and the attainment of the age of 24.

### The Naval Medical Service.

In recent years important changes have been made in the naval medical service with a view to secure increased efficiency. A consultative board has been introduced, consisting of three civilian physicians of eminence and two naval medical officers to bring the navy into touch with the medical profession outside the service and to introduce improvements in hospitals, both on shore and afloat. Special instruction of medical officers in the diseases of foreign stations with special wards for the study of such diseases has been established at Haslar. An institutional officer versed in these diseases has been placed in charge with an allowance of $750 per annum in addition to his ordinary pay and residence. Prizes for excellent work, a gold medal, a microscope, a silver medal, and books will be awarded to surgeons under instruction on the termination of the half-yearly sessions. The number of medical officers attending graduate instruction has been much increased, and such instruction is applicable not only to surgeons as formerly, but also to staff-surgeons and fleet-surgeons. A complete outfit of surgical instruments is supplied to all ships; the surgeon is now required to provide only a pocket case. The examinations have been remodeled. The examination for the promotion of surgeons to the rank of staff-surgeon will be conducted by the civil medical examining board with a naval medical officer for the examination in naval hygiene. Greater facilities and inducements are offered to the house officers of the large civil hospitals to enter the navy. Those who on entry hold, or are about to hold, such appointments, are allowed to serve on in that appointment up to one year, reckoning the time served for increase of their pay. Earlier promotion to the rank of staff-surgeon is also granted to these surgeons, and one year's seniority may be so gained. The period of service required of surgeons before undergoing examination for promotion has been reduced from eight to five years. The pay has been increased. Formerly a surgeon received $1,000 a year on entry, and an inspector-general $5,000, with quarters; the former now receives $1,250 and the latter $6,500. The regulations as to withdrawal from the service have been extended, and a surgeon may now be allowed to withdraw after four years' service, with a gratuity of $1,250, on condition of joining a reserve for service, in case of war or emergency, for a period not exceeding eight years.

### The National Hospital for the Paralyzed and Epileptic.

An appeal is being made for funds to prosecute researches into the origin of nervous diseases at this world-famous hospital. The object is to make provision for permanent and systematic pathologic work, so that the large available material of the hospital may not be lost to science, as most of it now is. It may be mentioned that investigations made at the hospital last year led to discovery that Landry's paralysis is due to a micrococcus.

## Correspondence.

### The Birth and Origin of Syphilis.

Baltimore, Jan. 28, 1904.

*To the Editor:*—I was surprised to find in The Journal, January 9, the following statement by Dr. Knott regarding "The Birth and Origin of Syphilis": "While so much mythologic lore remains connected with the origin of the great epidemic of syphilis which swept Europe at that date (the siege of Naples), it is no matter for surprise that the question of the existence of the disease in ancient times still remains a matter of dispute."

The fact is, venereal diseases embrace all periods of man's existence. It existed long before the Christian era, and all through the period of classical antiquity. It flourished in the free republics of Greece, and under the corrupt sway of the Roman emperors. The scholar should read the Fathers as authorities for the history of venereal disease, for their "Orationes Contra Gentes" especially afford much valuable material toward a knowledge of the moral condition of the nations of antiquity.

It is strange with what pertinacity and universal acceptance stories of the spontaneous birth of syphilis remain in the mind of man. Astruc and Gutanner put forth that childish fiction of the origin of syphilis being in the cohabitation of Columbus' men with the Indian maidens; but they forgot to tell us where the maidens contracted the disease. Hensler made every exertion to dissipate this puerile and unscientific tale, but so strong is the love for the romantic in our nature that his efforts were for a long time fruitless.

P. G. Klein[1] shows from annals of Malabar that long before the discovery of the West Indies venereal disease was known in the East Indies, for the Malabar physicians, Sangarasiar and Alessianambi, who lived more than nine hundred years ago, and other physicians before them, make mention of the disease and its cure by mercury. Dr. Wizman[2] made the disease arise in the second century in Dacia, which at that date was transformed into a Roman colony and had to welcome the licentious Roman soldiery. The excesses of these colonists, in a strange climate, and seconded by a combination of circumstances favorable to epidemic sickness, produced the disease, he said. Accordingly Wizman, as also Sprengel and Choulant, and, to some extent, Gruner, who considered the Moors to be the parents of the venereal disease, may be regarded as taking up an intermediate position between the two extreme views as were then held, i. e., the disease as a new one and as an ancient affection.

It is impossible in any limited space to give a chronologic account of the Venus cult of the people of antiquity, for it existed everywhere in the east under varying forms and names.[3]

It was at Babylon that the cult of Venus originated as Mylitta worship, spread over the inland parts to Mesopotamia as the Sabean religion, and was passed on by the Phoenicians to the seaboard people as Astarte—worship. During this period filth and lust prevailed, and is the constant complaint of the writers of the day. Juvenal, for instance (Satir 1, 104): *Mesopotameni homines effrenatal libidinis sunt in utroque sexu, ut Salustius meminit*—(The inhabitants of Mesopotamia are people of unbridled lustfulness in either sex, as Sallust records). The worship of Bacchus, and with it the phallic ritual, was transplanted to Greece and India. To explain the occasion of this introduction there is a legend related which certainly gives us an account of genital disease. It is given by Natalis Comes.[4] The author borrowed the legend from Periamder. It is also found in the *Scholiast* to Aristophanes; Acharn. 1: "There were phallic rites, too, established in honor of Dionysus (these were observed among the Athenians; for it was at Athens that the far-famed Pegasus first established the worship of Eleutherian Bacchus), at which men chanted hymns telling how the gods freed the Athenians from a plague, and how he was given of many good gifts to mortals." The story relates that Pegasus brought the images of Dionysus from Eleutheria, a city of Boeotia, to the land of Attica; but the Athenians slighted the god, and did not, as was their wont, receive him with a procession. "Wherefore the god was wroth, and afflicted the men's private parts with a disease that was most grievous to them." Sciopplus relates the same story in his edition of the Priapeia, and adds: "*Fuit autem morbus ille quem hodie gallicum vocamus*"—(but it was the disease which we nowadays call the French disease—syphilis). Almost the same trouble fell on the men of Lampsacus when the women began the cult of the worship of Priapus; "so they prayed to the gods to help them, and after some interval of time had elapsed (mark this careful noting of the elapse of a few days) a most grievous disease of the private parts attacked the men of Lampsacus.[5] William Lee Howard, M.D.

## Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

### WHY ARE SCIENTISTS POOR WRITERS?

San Francisco, Jan. 31, 1904.

*To the Editor:*—Your editorial Jan. 9, 1904, discussing why scientists are poor writers, aroused my spirit of refutation, because I think your point is not well taken. I am like the man who can neither provide nor prepare a good meal, but who can enjoy it when it is set before him; I am neither a scientist nor a good writer, but I can appreciate a good article. It all depends on the viewpoint. No doubt the scientist believes himself a good writer; it is the non-scientist who thinks he is not. The scientist loves to indulge in technicalities, precision and prolixity, while the less scientific man thinks them prosy and pedantic. The scientist scorns to reduce his style to the popular taste, while the popular writer "stoops to conquer." The scientist either loses himself in the mass of details and citations of authorities and statistics, thus putting his readers in the position of the person "looking for a needle in the haystack," or he so overwhelms them with facts that they feel as if they were wrestling with the effects of a banquet. We do not "see ourselves as others see us," and it therefore takes a non-scientific man to criticise a scientist and a scientist to squash his critic; that is your opportunity, and I presume you will make the most of it. E. G.

Answer.—Our correspondent's first sentence suggests that he intends refutation, what follows is instead confirmation. He has digressed from the subject and discussed the reader. We agree that a reader who is familiar with a subject, especially if he be himself a worker along that particular line of research, will understand, enjoy, and even approve a poorly written article, while one who is yet to be more than superficially interested in the subject will give it up as involving unnecessary and vexatious mental labor. Our correspondent uses the word "popular." By no means do we mean that an article should be popularized. That would be an insult to medical men. The physician of to-day must be able to understand the scientific terms that are almost daily being added to our vocabulary. An article may be full of hemolysis, amboceptors and agglutinins and yet be well written. Our correspondent should not fall into the error of the misuse of the word "scientific" and class articles as either "scientific" or "popular." It is a common error. We not infrequently are compelled to refuse publication to an article which contains valuable facts, but which is weighed down with so many imperfections as to discourage one—as does the porcupine—from closer investigation.

### LISBON INTERNATIONAL CONGRESS.

Michigan, Feb. 2, 1904.

*To the Editor:*—Will you let me know through The Journal the exact date of the International Medical Congress at Lisbon, and also when and how the delegates from the United States are appointed? A. E. G.

Answer.—The exact date has not been settled on so far as we know, except that it is to be in 1906. Neither have the regulations governing membership been issued. See The Journal, January 30, p. 320.

### TRAINING SCHOOL FOR MALE NURSES.

Dr. E. L. Mortimer, Baltimore, answering the query in The Journal January 30, says there is a training school for male nurses connected with Bellevue Hospital, New York City. The "Superintendent of Male Nursing School" should be addressed at 431 E. 26th street by any one interested.

## Marriages.

J. A. Bussell, M.D., to Miss Mary Coffee, both of Rochelle, Ga., January 20.

Charles Ulmer, M.D., to Miss Lora Angell, both of Bucyrus, Ohio, February 3.

Robert Bailey Nelson, M.D., to Miss Frances Hurt, both of Jackson, Tenn., January 27.

James Sterritt Caldwell, M.D., to Miss Estelle M. Riley, both of Cincinnati, January 28.

Joseph A. White, M.D., Dumas, Ark., to Miss Fanny Roberts of Pine Bluff, Ark., January 27.

A. Buford Green, M.D., to Miss Ida Elizabeth Vernon, both of Cartersville, Ga., January 27.

Wyllys R. Hodges, M.D., Baltimore, to Miss Mary E. Kline, at Montgomery, Pa., January 21.

Arthur Weber, M.D., New Orleans, to Miss Elizabeth Patterson of Smithville, Mo., January 27.

Samuel M. Worley, M.D., St. Augustine, Fla., to Miss Lizzie Belle Pressley of Elberton, Ga., January 18.

Herbert William Landon, M.D., Lansing, Mich., to Miss Dorothy Sterling of Monroe, Mich., February 6.

Frederick Clifton Moor, M.D., Tallahassee, Fla., to Miss Sara Margaret Howell of Washington, D. C., January 27.

## Deaths.

John Herbert Sangster, M.D. Toronto University, 1864, of Port Perry, Ont., died suddenly of heart disease in Toronto, January 27, aged 72. He was a notable figure in the medical life of Ontario. He was prominent both as an educator and as a practitioner. He was principal of the Toronto Normal School from 1866 to 1871, at the same time being professor of chemistry and botany in the old Dr. Rolph's School of Medicine, which subsequently became the Medical Faculty of Victoria University, but which is now defunct. On retiring from this principalship he removed to Chicago, but after a brief residence there, returned to Canada and began the active practice of medicine at Port Perry. In 1894 he was elected a member of the Ontario Medical Council.

Edwin Barnes, M.D. Albany (N. Y.) Medical College, 1865, a member of the American Medical Association, died at his home in Pleasant Plains, N. Y., January 22, aged 59, from pneumonia followed by acute indigestion, lasting two weeks. Dr. Barnes left his medical studies at Albany Medical College to join the Army, and served in the Department of the Cumberland of West Virginia, and of the East. He had been president of the Dutchess County Medical Society, and vice-president of the New York Medical Association, and at the time of his death was consulting physician and surgeon of Vassar Hospital, Poughkeepsie.

Harry Scott Vernon, M.D. Rush Medical College, Chicago, 1900, formerly house surgeon at the Chicago Policlinic, and health officer of Lewiston, Minn., a member of the American Medical Association, died at his home in Rushford, Minn., February 1, from pneumonia, after an illness of one day.

James W. Gordon, M.D. New York University, 1889, a member of the Bridgeport (Conn.) Medical Society, Fairfield County Medical Society and Connecticut Medical Society, died at his home in Sandy Hook, Conn., January 26, from heart disease, after a long illness, aged 41.

Brainerd Leaman, M.D. Jefferson Medical College, Philadelphia, 1864, a member of the American Medical Association; surgeon during the Civil War, and ex-president of the Lancaster County Medical Society, died at his home in Leaman Place, Pa., January 28, aged 62.

Moses W. Merryman, M.D. University of Maryland, Baltimore, 1850, of Baltimore County, Md., but for seven years a resident of Atlantic City, N. J., died at his home in that place, January 25, from cerebral hemorrhage, after an illness of one day, aged 76.

William H. Gale, M.D. Jefferson Medical College, Philadelphia, 1850, a member of the Maryland legislature in 1885, and for several terms register of wills of Somerset County, died suddenly at his home in Princess Anne, February 3, from acute indigestion, aged 76.

Robert C. Sharp, M.D. Jefferson Medical College, Pennsylvania, 1881, shot himself through the heart and died January

---

[5] Servius on Virgil, Geog. iv, p. 111.

20, while despondent on account of Bright's disease, at his home his home in What Cheer, Iowa, January 25.

**Henry Benson Phillips, M.D.** Vanderbilt University, Nashville, 1893, of Benson, La., died at the Sanitarium, Shreveport, La., February 3, from pneumonia following laryngitis, after an illness of ten days, aged 35.

**David Krausgill, M.D.** Medical College of Ohio, Cincinnati, 1879, a member of the American Medical Association, died at his home in Chesterton, Ind., January 23, from pernicious anemia, aged 56.

**John S. Yard, M.D.** University of Pennsylvania, 1886, who forsook medicine for architecture, died at his home in Trenton, N. J., January 23, from septicemia resulting from a retro-ocular abscess.

**Thomas E. Wakefield, M.D.** Castleton (Vt.) Medical College, 1843, president of the Rutland County Medical and Surgical Society in 1883, died at his home in Fairhaven, Vt., January 25, aged 82.

**Robert Lambert, M.D.** Faculty of Medicine of Queen's University, and Royal College of Physicians and Surgeons, Kingston, Ont., 1859, died at his home in Windsor, Ont., January 22, aged 82.

**Needham M. Wilson, M.D.** Jefferson Medical College, Philadelphia, 1866, died at his home in Philadelphia, January 19, three months after a fall, in which he sustained severe injuries, aged 67.

**J. Varnum Mott, M.D.** College of Physicians and Surgeons, New York, 1872, who retired from practice ten years ago, died suddenly from heart disease at his home in Boston, January 23, aged 53.

**Frank E. Luman, M.D.** Bellevue Hospital Medical College, New York, 1892, died at his home in Colusa, Cal., January 17, from the effects of an overdose of morphin, self-administered, aged 36.

**Robert Hanna, M.D.** Jefferson Medical College, Philadelphia, of Greenock, Pa., was run over and killed by a train on the Baltimore and Ohio Railroad near Guffey Station, January 20, aged 32.

**Hermann Lewek, M.D.**, surgeon of the Hamburg-American steamer *Patricia*, died January 20, a day after the arrival of the steamer in New York, from pneumonia, in the German Hospital.

**Byron Whitford, M.D.** New York University, 1878, some-time president and treasurer of the Providence (R. I.) Medical Association, died at his home in Providence, Feb. 8, 1903, aged 53.

**Fred A. Steinmeyer, M.D.** Homeopathic Medical College of Missouri, St. Louis, 1870, died at his home in Bonaparte, Iowa, January 27, from the effects of a fracture of the hip, aged 59.

**Charles S. Sargent, M.D.** Hahnemann Medical College, Philadelphia, 1881, died at his home in Stockton, Cal., January 29, from typhoid fever, after an illness of ten weeks, aged 43.

**Harrison L. Baird, M.D.** Vanderbilt University, Nashville, Tenn., 1890, died at his home in Asheville, N. C., January 22, from Bright's disease, after a protracted illness, aged 37.

**John Hannahan, M.D.** Kentucky School of Medicine, Louisville, 1893, was found dead in his apartments in Elwood, Ind., January 25, presumably from heart disease, aged 45.

**Francis Rudderow, M.D.** University of Pennsylvania, Philadelphia, 1887, was recently found dead on the stairway of his home in Philadelphia, after a long illness, aged 42.

**Walter D. Rexford, M.D.** Baltimore Medical College, 1898, of Deming, N. M., died at Las Vegas, N. M., January 16, from consumption, after a protracted illness, aged 30.

**Andrew B. Butler, M.D.** Northwestern Medical College of St. Joseph, Mo., 1881, died at his home in Madera, Cal., January 15, from pneumonia, after a brief illness, aged 55.

**David S. Griffith, M.D.** Jefferson Medical College, Philadelphia, 1863, died at his home in Florida Mesa, near Durango, Colo., January 21, from heart disease, aged 63.

**John R. Barnett, M.D.** Medical College of the State of South Carolina, Charleston, 1850, died at his home in Warren, Ark., two days after a fall, on January 24, aged 74.

**Albert A. Beane, M.D.** State University of Iowa, Iowa City, 1891, a member of the American Medical Association, died at his home in What-Cheer, Iowa, January 25.

**Alban Spooner, M.D.** Hahnemann Medical College, Philadelphia, died at his home in Beverly, N. J., January 18, from pneumonia, after a short illness, aged 26.

**Robert Faskett Bennett, M.D.** Rush Medical College, Chicago, 1853, of Elgin, Ill., died at the Illinois Northern Hospital for the Insane, in that city, January 24, aged 77.

**Henry W. Dudley, M.D.** New York University, 1877, died at his home in Hillsboro, Texas, January 19, from consumption, after an illness of several years, aged 49.

**E. Vernon Brower, M.D.** Physio-Medical College of Indiana, Indianapolis, 1897, of Richmond, Ind., died at Boston, Ind., from tuberculosis, January 29, aged 27.

**William H. H. Neville, M.D.** Hahnemann Medical College, Philadelphia, 1865, of Philadelphia, died suddenly in a street car in that city, January 22, aged 64.

**Robert G. Bryans, M.D.** Medical College of Georgia, Augusta, 1878, a member of the American Medical Association, died recently at his home in Jackson, Ga.

**Holly M. Mills, M.D.** Nebraska, the pioneer physician of Polk County, Neb., died at his home in Osceola, January 28, from cerebral hemorrhage, aged 69.

**Albert L. Dunn, M.D.** Eclectic Medical College, Philadelphia, 1853, died at his home in Oklahoma City, Okla., from cerebral hemorrhage, January 23, aged 76.

**Nels J. Lund, M.D.** Eclectic Medical College of Pennsylvania, Philadelphia, 1870, died in his office in Marinette, Wis., January 22, from apoplexy, aged 74.

**Jacob T. Mills, M.D.** Starling Medical College, Columbus, Ohio, 1872, died at his home in Columbus, January 31, after an illness of two years, aged 65.

**Phoebe Jane Babcock Wait, M.D.** New York Medical College and Hospital for Women, 1871, died at her home in New York City, January 30, aged 65.

**Jacob Slagle, M.D.** Miami Medical College, Cincinnati, 1877, died at his home in Troy, Ohio, January 29, from injuries sustained in a street-car accident.

**John D. O'Connor, M.D.** Rush Medical College, Chicago, 1899, died at his home in Chicago, January 30, from meningitis, after an illness of ten days, aged 29.

**William E. Moore, M.D.** Northwestern Medical College, St. Joseph, Mo., 1885, died at his home in Reserve, Kan., January 22, from consumption, aged 64.

**Carroll S. Parker, M.D.** University of Nashville, 1870, died at his home in Gibson, Tenn., January 19, from pneumonia, after a short illness, aged 55.

**Samuel Starr, M.D.** Hahnemann Medical College, Philadelphia, 1869, died at his home in West Chester, Pa., January 22, from heart disease, aged 63.

**Donald W. Barton, M.D.** Medical College of the State of South Carolina, Charleston, 1858, died suddenly at his home in Bamberg, S. C., January 20.

**John J. Brady, M.D.** Bellevue Hospital Medical College, New York, 1891, of Detroit, died at Deckerville, Mich., January 23, from heart disease, aged 37.

**Bennett H. Van Kirk, M.D.** Jefferson Medical College, Philadelphia, 1869, died at his home in West Newton, Pa., January 24, after a lingering illness.

**Henry M. Rector, M.D.** Missouri Medical College, St. Louis, 1893, died at his home in Hot Springs, Ark., January 22, after a long illness, aged 47.

**James H. Kyser, M.D.** Tulane University, New Orleans, 1897, died in Arizona, January 27, from consumption, after a prolonged illness, aged 33.

**Joseph J. Mayfield, M.D.**, 1850, of Bruceville, Ind., who retired from practice in 1880, died at his home in that place, January 25, aged 83.

**George Thompson, M.D.** Eclectic Medical College of the city of New York, 1881, died at his home in New York City, February 2, aged 87.

**John D. Henry, M.D.** Bellevue Hospital Medical College, New York, 1870, of Hedrick, Iowa, died in California, January 27, after a long illness.

**Samuel H. Huntington, M.D.** Yale University Medical Department, New Haven, Conn., 1876, died at his home in Wilton, Conn., January 22.

**Charles E. White, M.D.** Cleveland Homeopathic Medical College, died from diphtheria at his home in Cleveland, January 23, aged 30.

**William H. Hening, M.D.** Jefferson Medical College, Philadelphia, 1853, died at his home in Jefferson, Va., January 23, aged 74.

**Frederick W. Vandersloot**, M.D. University of Maryland, Baltimore, 1855, died at his home in York, Pa., January 13, aged 70.

**Dennis N. Conner**, M.D. University of Pennsylvania, Philadelphia, 1867, died at his home in Philadelphia, January 22, aged 59.

**George G. Jones**, M.D. University of Buffalo, 1886, died at his home in Geneseo, N. Y., January 25, after an illness of a year, aged 48.

**Charles H. Niman**, M.D. Bellevue Hospital Medical College, New York, 1880, died at his home in Elkhart, Ind., January 14, aged 40.

**Leander Blackwell**, M.D. Missouri Medical College, St. Louis, 1894, died recently at his home in South Windham, Conn., aged 36.

**Asa Whitford Brown**, M.D. Homeopathic Hospital College, Cleveland, 1853, died at his home in Providence, R. I., June 1, 1903.

**M. Marcus**, M.D. Medico-Chirurgical College, Philadelphia, died recently from pneumonia at his home in that city, aged 26.

**W. Stuart Hancock**, M.D., of Wytheville, Va., died at Honolulu, Hawaii, January 1, from consumption, after a long illness.

**Virgil M. D. Marcy**, M.D. University of Maryland, Baltimore, 1847, died at his home in Cape May, N. J., January 21, aged 81.

**Thomas F. Cawley**, M.D. Bellevue Hospital Medical College, New York, died at his home in Saylorsburg, Pa., January 28.

**P. H. Woolsey**, M.D., a well-known physician of Orange, Sullivan and Delaware counties, N. Y., died January 12, aged 80.

**Joseph A. Townsend**, M.D. Baltimore University School of Medicine, 1892, died recently at his home in Lake City, Fla.

**Soloman P. Stoddard**, M.D. University of Heidelberg, Germany, 1863, died at his home in Indianapolis, January 27.

**Walter Y. Winton**, M.D. Barnes Medical College, St. Louis, 1898, died at his home in Kirbyville, Texas, Dec. 11, 1903.

**Arthur C. Peirce**, M.D. University of Maryland, Baltimore, 1883, died at his home in Riverside, R. I., July 26, 1903.

**Richard J. Grigson**, M.D. Iowa Medical College, Keokuk, 1858, died at his home in Augusta, Ill., January 16, aged 73.

**Gaius H. Nash**, M.D. New York University, 1864, died at his home in New York City, January 23, aged 78.

**Arthur H. Ashley**, M.D., died at his home in Fruit Hill, S. C., January 23, after an illness of one week, aged 40.

**W. Cortland Stockton**, M.D., was found dead at his home in Bluffton, Ind., from dropsy, January 24.

**George Cook**, M.D. Victoria, 1864, died at his home in Toronto, Ont., Dec. 31, 1903, aged 62.

**James Carroll Jacobs**, M.D. Rhode Island, died at his home in Providence, Jan. 24, 1903, aged 69.

**O. T. Watkins**, M.D., died at his home in La Crosse, Ark., January 29, aged more than 80.

**Amos Ray Collins**, M.D. New York University, 1861, died in Taunton, Mass., Jan. 25, 1903.

**William L. Huston**, M.D., was burned to death in his home at Marengo, Iowa, January 30.

**Peter Broardt**, M.D. New York, died at his home in Buffalo, N. Y., January 21, aged 70.

**William H. Woods**, M.D., died recently at his home in Owatonna, Minn., aged 80.

**U. M. Humble**, M.D. Illinois, died at his home in Iuka, Ill., in January, aged 73.

**Harry J. Maynard**, M.D., of Cheyenne, Wyo., died in Denver, January 26.

**John M. Owensby**, M.D., died at his home in Denison, Texas, January 30.

### Deaths Abroad.

**H. F. A. Peypers**, M.D., died at Amsterdam, January 15. He founded eight years ago the well-known international journal *Janus*, devoted to the interests of the history of medicine and medical geography.

**J. Seegen**, M.D., noted for his research on diabetes, glycogen formation and elimination of nitrogen, died at Vienna, January 24, aged 81. He first settled at Carlsbad and has always ranked among the leading balneologists of the day. His views in regard to the sugar formed in the liver as the exclusive source of mechanical energy and heat have been combated by Pflüger. Among the problems which he was studying up to the time of his death are the absence of glycogen in the liver after death by suffocation, and also the continuance of the glycogen formation in excised scraps of liver tissue kept in alcohol, which arrests all fermentative and cellular action.

**P. Dettweiler**, M.D., died at Kronberg, January 13, aged 66. He is considered the father of the modern physico-dietetic methods of treating tuberculosis. He was a military surgeon for a few years until his lungs became affected, after which he attached himself to Brehmer at Gorbersdorf, and dedicated his entire life to the study of tuberculosis. He introduced the method of treating consumption by reclining in the open air, and published a number of works on tuberculosis. In 1876 he founded the sanatorium at Falkenstein, which has been the model for so many since. He conducted it personally until 1895. To him the world owes in large measure the revival of the belief that tuberculosis is curable.

## Book Notices.

LA NEVRASTENIA. Con proemio del Prof. Clodomiro Bonfigli, Direttore del Manicomio di Roma. By Dott. Luigi Cappelletti, Vice-Direttore del Manicomio Provinciale di Ferrara. Milano: Ulrico Hoepli. 1904.

The Hoepli manuals comprise a large number of valuable little compends, they are often more than mere compilations, and many are written by men of wide reading, more or less authorities in the branches discussed. Among these we may include this little volume, and the preface, by Professor Bonfigli, fairly states its standing. The author has reviewed the subject thoroughly, and gives us one of the best brief general epitomes of the literature that we have in any language. It, of course, is available only to Italian readers at present. One of the special features of the book is an extensive bibliography of nearly 1,200 titles in which nearly all the important memoirs and works on the subject are included. There are many omissions in the English and American literature, but the more important articles have generally been included. Neurasthenia has been called an American disease, but one has only to look at this list of European literature on the subject to see that it is about as much a matter of serious consideration in almost every European country as it is here. In fact, the more serious forms are probably fully as common there, if not more so, than among us. As might be expected, Beard is the author most extensively quoted, though others such as Bouveret, De Fleury, De Giovanni, Charcot, Krafft-Ebing, Morselli and a few others are not much behind.

A NARRATIVE OF MEDICINE IN AMERICA. By James Gregory Mumford, M.D., Assistant Visiting Surgeon to the Massachusetts General Hospital. Cloth. Pp. 508. Price, $3.00. Philadelphia and London: J. P. Lippincott Co. 1903.

We can not hear *too* much about the hardy, practical, medical pioneers of our country. While each one who attempts to give us a biographical sketch of the founders of American medicine must necessarily repeat much that is already known; still each will find something new to say, and will present the old in a different manner and from a different point of view. We are, therefore, glad to welcome another book on the American medical pioneer and on medicine during pioneer days. The author does not assert that he gives a complete list of those of our predecessors whose names are to be found in the early annals, but he takes a few of the conspicuous ones in each era to illustrate, as it were, the conditions of that particular time. The narrative stops at the middle of the last century. A chapter is devoted to the discovery of ether, with an extremely fair statement regarding that unhappy controversy. The chapter on the founding of the American Medical Association is an interesting and instructive one; in it the author gives some inside history that is not generally known. The book is a readable one, and interesting as well as instructive. We have but one fault to find, and that is the almost universal use of the word "doctor." In the very first sentence we read: "The English brought their doctors with them," although we are not told whether this means doctors of divinity or some other kind. We have doctors of music, doctors of dentistry, doctors of divinity, doctors of law, etc. It is bearable to have the word occur occasionally, but our author seems to be in love with it and uses it so much that it mars the reading. In spite of this criticism, we can only repeat that the book is not only readable, but a valuable addition to the early medical history of our country.

Lesson on Massage. By Margaret D. Palmer, Masseuse and Manager of the Massage Department of the London Hospital. Second Edition. Cloth. Pp. 261. Price, $2.50. New York: William Wood & Co. 1904.

In this second edition there have been some minor improvements and the addition of chapters on the Nauheim treatment and on bandaging. The book is intended for the first study by the masseur or nurse, and is a very good book for the physician to recommend for this purpose. The summary of anatomy is complete and well selected and arranged.

## State Boards of Registration.

### COMING EXAMINATIONS.

Regular Board of Medical Examiners for Georgia, Atlanta, March 3. Secretary, I. H. Goss, M.D., Athens.

Regent of the State Board of Medical Examiners of New Hampshire, State House, Concord, March 1-2. Regent, Channing Folsom, M.D., Concord.

Board of Registration in Medicine for Massachusetts, State House, Boston, March 8-9. Secretary, Edwin B. Harvey, M.D., State House, Boston.

Committees of Examination of Connecticut, New Haven, Hartford and Waterbury, March 8. Secretary, Prof. C. A. Lindsly, New Haven.

Maine Board of Registration of Medicine, Portland, March 23. Secretary, A. K. P. Meserve, M.D., Portland.

Maine Report.—Dr. A. K. P. Meserve, secretary of the Maine Board of Registration of Medicine, reports the examination, partly oral and partly written, held at Augusta, Nov. 11, 1903, as follows: Subjects, 9; questions, 90; percentage required, 75; candidates, 18, all of whom passed. The candidates are summarized below by colleges, the year of graduation and grade of each being given.

PASSED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Kentucky School of Medicine | (1903) | 82 |
| University of Michigan | (1898) | 93 |
| Harvard University | (1901) | 94 3/7 |
| Laval University (Quebec) | (1903) | 83 6/7 |
| Boston University Medical School | (1903) | 90 3/7 |
| University of Maryland | (1903) | 84 6/7 |
| Columbia University | (1896) | 90 2/7 |
| Chattanooga Medical School | (1903) | 78 4/7 |
| Medical School of Maine | (1901) | 88 4/7 |
| McGill University | (1903) | 91 3/7, 85 4/7, 85 3/7 |
| Univ. of Pennsylvania | (1903)<br>(1901)<br>(1887) | 90 1/7<br>88.2<br>90 2/7 |
| Laval Univ. (Montreal) | (1903)<br>(1901)<br>(1899) | 88 4/7<br>90 2/7<br>86.9 |

Rhode Island Report.—Dr. G. T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, Jan. 7 to 8, 1904, as follows: Subjects, 11; questions, 70; percentage required, 75; candidates, 12; passed, 11; failed, 1.

PASSED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Bowdoin College | (1903) | 76.4 |
| College of Physicians and Surgeons, Baltimore | (1903) | 78.7 |
| College of Physicians and Surgeons, New York | (1903) | 75.7 |
| Dartmouth College | (1896) | 89.1 |
| Georgetown University | (1903) | 88.2 |
| Harvard University | (1901) | 93.6 |
| Manitoba Medical College | (1891) | 79.4 |
| Medico-Chirurgical College, Pennsylvania | (1898) | 76.5 |
| Tufts College, Boston | (1896) | 76.6 |
| University of Maryland | (1892) | 84.0 |
| University of Vermont | (1903) | 85.4 |

FAILED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| College of Physicians and Surgeons, Baltimore | (1902) | 70.0 |

Minnesota Report.—Dr. C. J. Ringnell, secretary of the Minnesota State Board of Medical Examiners, reports a written examination held at St. Paul, Jan. 5 to 7, 1904, as follows: Subjects, 12; questions, 95; percentage required, 75; candidates, 27; passed, 24; failed, 3.

PASSED.

Medical Department of the University of Minnesota, (1902) 78.3†, (1899) 77.6*.
Johns Hopkins Medical School, (1902) 83.9.
Medical Department of the University of Iowa, (1891) 78.3†, (1902) 77.6.
Rush Medical College, (1903) 78.4, 87.1, (1902) 82.1, (1900) 87.3.

Northwestern University Medical School, (1901) 87.3.
Barnes Medical College, (1900) 76.9.
Trinity University, (1900) 83.5.
Imperial Alexander's University, (1896) 83.3.

FAILED.

Hamline University, (1903) 65.8*, 67.1.
College of Physicians and Surgeons, Keokuk, (1884) 56.

* Second examination. † Third examination.

The following questions were asked:

DISEASES OF WOMEN.

1. Describe Alexander's operation and state under what condition it is indicated. 2. Acute oöphoritis, etiology, symptomatology and treatment. 3. Infectious vaginitis, varieties and causes of each, symptomatology and treatment. 4. Rectovaginal fistula, etiology, symptomatology, diagnosis and treatment. 5. Curettage of the uterus, give indications for and describe operation.

DISEASES OF CHILDREN.

1. Bronchopneumonia, etiology, pathology, symptomatology, diagnosis and treatment. 2. Rachitis, etiology, symptomatology, pathology, prognosis and treatment. 3. Chorea, etiology, symptomatology, prognosis and treatment. 4. Influenza, etiology, pathology, symptomatology, diagnosis, prognosis and treatment. 5. Chronic constipation of infancy, causes, prognosis and treatment.

HISTOLOGY AND PATHOLOGY.

1. Give a histologic description of the mammary gland. 2. Give a histologic description of the ovary. 3. Define and give classification of glands. 4. What morbid changes take place in the kidney in tubercular nephritis? 5. Give the pathology of chronic arteritis. 6. Give the pathology of empyema. 7. Describe fatty and amyloid degeneration. 8. Name some of the animal parasites found in man. 9. Give the clinical significance of leukocytosis, and the normal leukocyte count in the male and female. 10. Describe fully how you would prepare, stain and examine sputum for the presence of tubercle bacilli.

OBSTETRICS.

1. What bones enter into the formation of the pelvis? Give diameters of the superior strait of the pelvis. 2. What are the different positions of the head in vertex presentation? 3. What if any other presentation of the head is there? How would you manage these cases if conducting them? 4. Eclampsia? Causes? Treatment? 5. Give treatment for prolapsus funis. 6. How do you conduct third stage of labor? 7. What conditions would cause you to advise (*a*) embryotomy? (*b*) Cesarean section? (*c*) Premature labor? 8. What antiseptic precautions do you use in conducting a case of labor in so far as it affects the welfare of (*a*) mother? (*b*) Of child?

ANATOMY.

1. Describe the femur. 2. Name the bones which form the wrist joint. 3. Describe the sartorius muscle, giving origin and insertion. 4. Describe the aorta, naming its divisions. 5. Outline the portal circulation. 6. Describe the solar plexus. 7. Describe the thoracic duct. 8. From what is the serous investment of the stomach derived? 9. Into what parts is the brain divided? 10. Give general description of the tongue.

THEORY AND PRACTICE OF MEDICINE.

1. Give general classification of anemia, and give causes. 2. Define tachycardia and give causes. 3. Give definition and prognosis of rheumatoid arthritis. 4. Give prognosis and treatment of hemoptysis. 5. Give symptoms and treatment of Basedow's disease. 6. Briefly outline the differential diagnosis between typhoid fever and acute miliary tuberculosis. 7. Give the clinical varieties of dysentery and the different ways in which it occurs. 8. Name three common factors in the production of ascites, and give five abdominal conditions from which it must be differentiated. 9. Give varieties and treatment of round worms. 10. Give causes of intestinal obstruction.

SURGERY.

1. Give diagnosis and treatment of renal calculus. 2. Describe a tracheotomy. 3. Give technic of ligation of common carotid. 4. Describe operation for hare-lip. 5. Give technic of skin grafting. 6. Give treatment for necrosis in shaft of bone. 7. Give treatment for synovitis with effusion. 8. Give treatment for fracture of the body of a vertebra. 9. Diagnosis and treatment for fracture of inferior maxillary. 10. Briefly, treatment for infections in general.

EYE AND EAR.

1. Define tinnitus aurium; amblyopia, keratitis, myopia and blepharitis. 2. Give symptoms and treatment of trachoma. 3. What is iridectomy and when is it indicated? 4. Differentiate between acute iritis and acute glaucoma. 5. Give symptoms and treatment of acute otitis media.

CHEMISTRY, URINALYSIS AND TOXICOLOGY.

1. Give symptoms and treatment of carbolic acid poisoning. 2. Define molecule, inorganic chemistry, toxicology, atom and ptomain. 3. Differentiate between fermentation and putrefaction. 4. Give a quantitative and a qualitative test for sugar in the urine. 5. What is Marsh's test for arsenic?

PHYSIOLOGY.

1. Take up, briefly and in your own way, the subject of hemoglobin and oxy-hemoglobin. 2. Explain the abnormal amount of albumin present in the urine in a case of acute desquamative nephritis, from a purely physiologic standpoint, and, in a general way, what conditions, pathologic or other, influence the amount of serum-albumin eliminated by the kidney. 3. Follow the process of reproduction after conception has taken place (omitting the previous steps of the process). 4. Tell something of white corpuscles, including their behavior under certain conditions of health and disease. 5. Does the cause of the rhythmic heart beat lie within the

heart itself, or in the central nervous system? Can you suggest any experiment tending to prove the correctness of your answer to the above question? 6. If the vagus nerves were cut what effect would this have on the frequency of the heart-beat, and why? 7. Show how the lacteals take up and dispose of their share of products of food digestion. 8. Define and classify enzymes. 9. Name and give sources of two ferments which enter into the process of food digestion. 10. What is the function of the posterior columns of the spinal cord?

### MATERIA MEDICA AND THERAPEUTICS.

1. Give the temperatures (Fahr.) respectively of a cold bath, a tepid bath, a hot bath. 2. Describe the process of peptonizing milk. 3. Name the three best hypnotics and the average adult dose of each. 4. Write a prescription for an ointment for a case of psoriasis. 5. Criticise this prescription for an adult:

℞. Hydrargyri protoiodidi........................grs. iv.
Potassii iodidi........................drachms ij.
Aquæ........................................oz. iv.

Misce et solve. Sig.: Dose, a teaspoonful in water three times a day.

6. Give the adult dose of sulphate of atropia; arsenious acid; extract of cannabis indica; nitroglycerin; acetate of lead. 7. What is the source of cantharides, the name of the official preparation for internal use and the average dose for an adult? 8. What is the active principle or principles of Fowler's solution, of paregoric, of compound cathartic pills, of compound licorice powder, of Vienna paste? 9. What is the best preparation of lead for external use? 10. Prescribe iron as a tonic in pill form for an adult.

### HOMEOPATHIC MATERIA MEDICA.

1. What in brief is the general physiologic action of aconite? 2. Give four characteristics of aconite. 3. What are the characteristic stomach symptoms of pulsatilla? 4. In what class of patients is nux vomica most applicable, and mention three general characteristics of the drug? 5. Differentiate between bell., hyos. and stram. in delirium. 6. Give five characteristics of ars. alb. 7. Differentiate between phos. rumex and bell. in coughs. 8. What are the skin symptoms of graph. mez. and petroleum? 9. Give indications for merc. bin. in throat affections. 10. Differentiate between rhus and bry. in rheumatism.

### ECLECTIC MATERIA MEDICA AND THERAPEUTICS.

1. Name some remedies to be used in treatment of frostbites; of burns, and tell how you would use them. 2. Give the symptomatology and dose of sanguinaria, ipecac, asclepias and strophanthus. 3. In a case of la grippe, what remedies would you likely find indicated and how would you use them? 4. What is the physiologic action of cascara sagrada, hydrargyrum, elaterium and baptesia; give the medicinal dose of each? 5. Give conditions calling for use of iron, and name some of the best iron compounds. 6. Give use and dose of saw almetto, buchu, and *Rhus aromatica*. 7. Give dose and use of *Cratægus oxycanthus;* when would you combine it with apocynum? Write a prescription for such a combination. 8 What remedies would you need in treating a case of delirium tremens? Give conditions in which you would use each, and the dose. 9. What is the matter with the following:

℞. Hydarg. chl. mite........................gr. iii.
Calcium sulphid........................gr. v.
Sac. las........................gr. xxiv.

M. Ft. chart. No. 12. Sig.: Take powder every two hours.

℞. Potassium iodid........................gr. iii.
Quinin........................gr. i.
Syr. aurant........................ʒss.
Aqua ad........................℥ii.

M. Sig.: Take as directed.

10. What is the dose of trional, strychnia sulph., belladonna, aconite, lobelia, nitroglycerin?

### MEDICAL JURISPRUDENCE.

1. What is the postmortem evidence of live birth? 2. How soon does a body exposed to the air in summer begin to decompose? 3. What is medical malpractice? 4. What are the chief physical characteristics of the fetus at the end of the third month of gestation? 5. With what conditions is acute morphia poisoning most likely to be confounded?

# Association News.

## THE ATLANTIC CITY SESSION.

### Arrangements Being Perfected—Committees are Active.

Dr. Philip Marvel, secretary of the Committee of Arrangements for the next annual session of the American Medical Association, to be held at Atlantic City, N. J., June 7-10, 1904, reports that the arrangements are assuming good form with the prospect of completeness, except in the smaller details, at a comparatively early date. The hotel bookings are already very active, and the hotel committee urges those who are desirous of first-class quarters to arrange for them without delay. The list of houses in The Journal last week contains only the few selected as headquarters for the sections. For the members who have no particular reason for selecting accommodations at any one of these hotels, there are a hundred or more of other hotels at which good accommodations may be had. Dr. Marvel will be glad to furnish any further information desired by members of the Association from time to time, when requested. The personnel of the committee and the chairmen of the subcommittee are as follows:

Dr. B. C. Pennington, chairman; Dr. J. A. Joy, treasurer; Dr. E. A. Reilly, registrar; Dr. Philip Marvel, secretary.

### CHAIRMEN OF SUBCOMMITTEES.

Dr. W. Blair Stewart, Finance.
Dr. Walter Reynolds, Halls and Meeting Places.
Dr. E. A. Reilly, Registration.
Dr. A. D. Cuskaden, Exhibits.
Dr. Theo. Senseman, Entertainments.
Dr. E. C. Chew, Bureau of Information.
Dr. Emery Marvel, Banquets.
Dr. Edward Guion, Printing.
Dr. W. E. Darnell, Hotels.
Dr. Joseph F. DeSilver, Badges, etc.
Dr. W. P. Connaway, New Membership.
Dr. J. M. Marshall, Transportation.

New members for the month of January, 1904:

### ALABAMA.

Harper, G. H., Manistee.
Wheeler, T. T., Steele.
Howell, J. R. G., Dothan.
Welch, S. W., Talladego.
Letcher, Jos. B., Shorter.
Dixon, D. P., Thomas.
Cullens, F. B., Ozark.
Rountree, W. S., Wylam.
Walker, Jos. C., Mayline.
Lathem, S. N., Blossburg.
Martin, Wm. G., Adamsville.
Stallworth, E. L., Evergreen.
Rogan, B. B., Selma.

### ARKANSAS.

Rosamond, J. H. E., Grand Lake.
Thorn, J. W., Clio.
Thomas, Philip E., Clarendon.
Morgan, Chas. M., Camden.
Jacobs, Jesse Jackson, Webb City.
Hamilton, A. J., Calmer.
Hartsell, Wm. L., Pansy.
McKenzie, A. H., Casa.
Meek, J. W., Camden.
Osborne, J. M., Wiville.
Corn, J. S., Nashville.

### CALIFORNIA.

Sharp, Jas. G., San Francisco.
Crise, David, Escondido.
Mosgrove, Anna Marie, San Francisco.
Middleton, Johnson Van Dyke, San Francisco.
Thorwick, Martha G., San Francisco.
Poore, Jas. E., Sacramento.
Eckardt, A. O., Gualala.
Oliver, H. R., San Francisco.
Bryant, Chester M., Redding.
O'Connor, Jas. H., San Francisco.
Lucas, Wm. Thos., Santa Maria.
White, David W., San Bernardino.
Gardner, Sam'l Jas., San Francisco.
Taylor, Oscar N., San Francisco.
James, J. W., Sacramento.

### COLORADO.

Peden, B. A., Manzanola.
Cooke, John M., Colorado Springs.
Neeper, Edw. R., Colorado Springs.
Roberts, Judson O., Cripple Creek.
Beck, L. H., Manitou.
Condit, H. C., Florence.
Hawes, Mary, Denver.
Nesmith, Frances M., Denver.
Harlow, Wm. P., Boulder.

### CONNECTICUT.

Day, F. L., Bridgeport.
Mulcahy, Thos. A., Hartford.
Whittemore, Edw. Lancaster, New Britain.
Mayer, Nathan, Hartford.
Wilson, Wm., Wallingford.
Rand, Richard Foster, New Haven.
Stevens, Frank W., Bridgeport.
McDonnell, Ralph A., New Haven.
Rowley, Alfred W., Hartford.
Ellis, Thos. L., Bridgeport.
Goodrich, Chas. A., Hartford.
Varno, Henry G., Thompsonville.
Tukey, F. M., Bridgeport.
Botsford, Chas. P., Hartford.
Gold, Jas. D., Bridgeport.
Hyde, F. C., Greenwich.

### FLORIDA.

Maynard, B. H., Webster.
Kinsey, Junius P., Lamont.
Weedon, L. W., Tampa.

### GEORGIA.

Barnum, R. E. L., Richland.
Adair, Robt. E., Taylorsville.
Thrash, Elmore C., Oakland.
Bomar, E. P., Ohoopee.
Clarke, L. B., Atlanta.
Kemp, A. P., Barnesville.
Jennings, W. J., Blakely.
Hunter, A. P., Tifton.
Borders, Dennis J., Calhoun.
Bell, Addison K., Madison.
Davis, Jas. P., Tennill.
Neal, Jos. W., Scotland.
Jones, Wm. T., Atlanta.
Fischer, L. C., Atlanta.
Comer, Ralph, Tignall.
Elder, Eugene B., Macon.
Bush, Oliver B., Cairo.
Roberson, G. W., Macon.
Harper, Aubrey, Wray.

### ILLINOIS.

Nichols-Schmalling, Hannah, Fulton.
Dunham, Frank, Robinson.
Tallman, E. D., Chicago.
Mann, Alban L., Elgin.
Buzik, Julius, Chicago.
Wales, R. P., Mt. Carroll.
Friedberg, S. A., Chicago.
Harmon, Henry, Chicago.
Bennett, Wm. H., Chicago.
Hall, S. B., Rock Island.
Taliaferro, Frank, Chicago.
Brown, Alice Barlow, Chicago.
Schwuchow, Walter B., Princeton.
Stowell, L. E., Williamsfield.
Pridmore, Geo. W., Industry.
Starkey, Harvey L., Junction.
Hay, E. J., Millersburg.
Palmer, Geo. T., Chicago.
Friedberg, S. A., Chicago.

### INDIANA.

[illegible]
[illegible] lish.
[illegible]
Barandy, Oscar von, So. Bend.
Mansfield, Thos. J., Muncie.
Thompson, Wilson H., Matthews.
Zaleski, Jos. P., So. Bend.
Giltner, H. A., Lexington.
Pettigrew, Chas. D., Houston.
Beard, E. R., Liberty.
Whetsell, Leon E., Bloomington.
McCracken, A. J., Richmond.

### IOWA.

Leffler, Edw. G., La Porte City.
Dunkelberg, E. E., Waterloo.
Thompson, G. B., Winthrop.
Smith, Ralph, Red Oak.
Sala, Ono P., Davenport.
Brunig, H., Mineola.
Sigworth, Jr., H. W., Anamosa.
Boice, C. A., Washington.
Washburn, T. R., Donnellson.
Greensfelder, Louis A., Chicago.
Stoecks, Wm. A., Davenport.
DeGraff, Elmer B., Davenport.
Noe, Chas. T., Amana.
Boes, F., Davenport.
Holtsclaw, Z. T., Larchwood.
Johnston, E. N., Fredericksburg.
Amdor, Frank P., Carbon.
Bowen, Will, Ft. Dodge.

### KANSAS.

Peers, T. W., Topeka.
Relihan, D. W., Smith Center.

### KENTUCKY.

Ward, J. Scott, Pineville.
Evans, Will K., Pineville.
Calvert, J. H., Milton.
Hiestand, C. V., Merrimac.
Jasper, Galen E., Waterloo.
Heath, Chas. L., Lindsay.

Wallingford, J. Stuart, Paris.
Thornton, Geo. G., Lebanon.
Bloch, Leo, Louisville.
Jones, L. O., Hebbardsville.
Paschall, A. F., Crossland.
Flack, T. D., Louisville.
Clark, H. C., Falmouth.

### LOUISIANA.

Kellogg, Wm. A., Innis.
Stewart, G. McG., Laurel Hill.
Hunter, Edwin W., Gallion.
Abramson, Louis, Shreveport.
Botts, Wm. F., Shreveport.
Mobley, Jesse Woods, Allentown.

### MAINE.

Cummings, E. S., Lewiston.
Lamb, Frank W., Portland.
Dyson, Wallace W., Portland.
Lewis, Philip P., Gorham.
Bryant, Bertram L., Bangor.

### MARYLAND.

Ruhrah, John, Baltimore.
Hartman, Jacob H., Baltimore.
Thomas, Richard H., Baltimore.
Hemmeter, John C., Baltimore.
Cathell, D. W., Baltimore.
Larned, Chas. W., Baltimore.
Riely, Compton, Baltimore.
McCormick, Thos. P., Baltimore.
Davis, Jr., John Staige, Baltimore.
Whitney, E. L., Baltimore.

### MASSACHUSETTS.

Bartol, John W., Boston.
Blanchard, R. H., Pittsfield.
Greene, Thos. F., Roxbury.
Wilbur, Sarah M., Springfield.
Harris, C. E., Hyannis.
Calkins, Irving R., Springfield.
Rollins, Edwin T., Boston.

Baker, Osmyn, Northampton.
Greene, Edw. M., Boston.
Ryder, Jas. W., Boston.
Chapman, Chas. R., Springfield.
Wentworth, Wm. W., Pittsfield.
Pierson, Edward L., Salem.
Wetherell, Arthur B., Holyoke.
Hutchinson, Edwin D., Westfield.
Jackson, Chas. W., Monson.
McKeen, Sylvester F., Allston.
Clarke, Louis H., Holyoke.
Cushing, Hayward W., Boston.
Bernard, Barnard L., So. Boston.
Burnham J. Forrest, Lawrence.
Bates, W. S., Barre.
Dennett, Daniel C., Winchester.

### MICHIGAN.

Eldred, Joseph N., Chesaning.
Harrison, L. C., Battle Creek.
Barney, L. S., Leonidas.
Grant, F. E., Athens.
Bayley, Wesley G., Carlton Center.
Maas, Rudolph J., Hancock.
Blaisdell, R. H., Sheridan.
Bell, T. H. E., Montgomery.
Jones, L. C., Kalamo.
Cochran, L. E., Peck.
Friedlander, Bernhard, Sebewaing.
Kelly, Edw. H., Ironwood.
Evans, E. J., Rockland.
Lawton, G. W., Jennings.
Orton, Ellsworth, Waterford.
Schultz, Samuel, Coldwater.
Maxwell, Jas. E., Decatur.
Belanger, Henry, River Rouge.

### MINNESOTA.

Werner, O. S., Lindstrom.
Wood, Douglas F., Hanska.
Lewis, W. W., St. Paul.
Meade, C. J., St. Paul.

### MISSISSIPPI.

Crook, H. L., Jackson.
Mitchell, C. D., Pontotoc.
Biles, J. D., Sumner.
Hamilton, Wm. W., Brooksville.
Price, T. M., Raymond.
Coker, D. W., Tunica.
Frizell, Jr., W. H., Brookhaven.
McCain, Geo. H., Coldwater.
Garrison, H. F., Seminary.
Pollard, Marquis L., Eden.
Barksdale, J. W., Valden.
Backstrom, John G., Tutwiler.

### MISSOURI.

Lindley, W. T., Hamilton.
Clark, Chas. E., Kansas City.
Neff, Robt. L., Joplin.
Hempel, Max, St. Louis.
Williams, Ira, Maitland.
Dunigan, Jas. P., Sullivan.
Luscher, L. W., Kansas City.
Henderson, F. L., St. Louis.
Horwitz, M. R., St. Louis.
Simmons, B. B., Oregon.
Bullock, F. E., Forest City.
Krebs, F. J. V., St. Louis
Anderson, J. N., Conway.
Murray, E. W., Parkville.
McEuen, O., Shannondale.
Dallas, L. W., Hunnewell.
Edmonds, O. R., Tina.
Van Eman, F. T., Kansas City.
Norris, T. J., Macon.

### NEBRASKA.

Campbell, Thos. F., Cody.
Devries, J. S., Fremont.
Sundbury, P. A., Holdrege.
Hull, Geo. M., Kearney.
Wiley-Ralston, Adda, Omaha.
Beck, F. L., Ong.
Fleming, H. C., Falls City.
Baxter, Mark Wm., Prosser.
Sadler, W. W., Bee.
McDonald, Jas. L., Atkinson
Hoff, A. E., North Bend.
Peterson, Wm. A., Elgin.
Waller, Jos. E., Salem.
Myers, E. M., Bennet.
Orr, H. W., Lincoln.
Weidner, S. S., Fairbury.

### NEW HAMPSHIRE

Huckins, T. H., Tilton.
Morey, G. B., Manchester

### NEW JERSEY.

Wintersteen, J. B., Moorestown.
Koch, L. A., Newark.
Pinneo, F. W., Newark.
Hawkes, E. W. Z., Newark.
Berner, David, Egg Harbor City.
De Silver, J. F., Atlantic City.

Foster, William J appointed A A surgeon at Lexington Mich, for examination of keepers and surfmen of the Life Saving Service

## Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service during the week ended Feb 5, 1904

SMALLPOX—UNITED STATES

District of Columbia Washington, Jan 23 30, 1 case
Florida Jacksonville Jan 23 30 4 cases
Indiana Evansville Jan 23 30 2 cases
Iowa Des Moines Jan 23 29 1 case
Louisiana New Orleans Jan 23 30, 2 cases, 1 case imported
Maine Orono, Jan 22, 1 case
Michigan Jan 23 30 Detroit, 1 case; Flint, 1 case, Grand Rapids 2 cases
Missouri St Louis, Jan 23 30, 13 cases
New Hampshire Manchester Jan 23 30 2 cases
New Jersey · Camden, Jan 23 30, 1 case, 1 death
New York: Buffalo, Jan 22 29, 1 case
Ohio Jan 23 30, Bucyrus, 4 cases, Warren, 1 case
Pennsylvania Jan 23 30, Allentown, 1 case, Erie, 1 case; Johnstown, 2 cases; McKeesport, 5 cases, Philadelphia, 65 cases, 17 deaths: Pittsburg, 15 cases, 1 case imported; Reading, Jan 25 Feb 1, 2 cases; Williamsport, Jan 24 31, 1 case
Utah Salt Lake City, Jan 23 30, 1 case
Wisconsin Milwaukee, Jan 23 30, 3 cases

SMALLPOX—FOREIGN.

Austria: Prague Jan 2 9, 5 cases
Brazil: Rio de Janeiro, Dec 27 Jan 3, 41 cases, 27 deaths
China. Shanghai, Dec 21 29, 1 case 1 death.
France Paris, Dec 26 Jan 16 50 cases, 3 deaths
Great Britain · Jan 8 16 Edinburgh 9 cases, Leith, 1 death, Liverpool, 1 death; Manchester, 1 case; Newcastle on-Tyne, 2 cases, Sunderland, 6 cases, 1 death; Glasgow, Jan 15 22, 65 cases, 4 deaths; London, Jan 2-16 10 cases
India · Bombay, Dec 29 Jan 5, 3 deaths; Karachi, Dec 27 Jan. 3, 7 cases, 1 death
Mexico: Tampico, Jan 10 24, 11 cases
Netherlands · Amsterdam, Jan 8 16, 2 cases, 1 death
Russia Dec 26 Jan 2, Moscow, 5 cases, Odessa, 2 cases; St Petersburg, Jan 2 9, 24 cases, 1 death.
Spain: Santander, Jan. 10 17, 2 cases

YELLOW FEVER.

Africa: Grand Bassam,, Dec 12, present
Brazil: Rio de Janeiro, Dec 28 Jan 3 2 cases
Mexico · Vera Cruz, Jan 16 23 1 case
Panama: Panama, Jan 5 12 3 deaths
Venezuela: La Guaira, Jan 2 9, present

PLAGUE

British Burmah. Rangoon Dec 9, 1 death
China. Hongkong Dec 5 12, 1 case 1 death
India Bombay, Dec 29 Jan 5, 125 deaths, Karachi, Dec 27 Jan 3 7 deaths
South Africa Natal (Pietermaritzburg), Dec 5 3 cases, 2 deaths

CHOLERA

Straits Settlements Singapore, Dec 5 19, 3 deaths
Turkey in Asia · Dec 28 Jan 4, Diarbokir, 15 deaths; Inobe, 1 case 1 death, Latakiah, 11 cases, 7 deaths, Mossul, 1 case, 1 death, Mussieb, 18 cases, 18 deaths; Kerbela, Dec 21-23, 15 deaths

# Medical Organization.

## Indiana.

Benton County Medical Society.—This society was reorganized February 1, with the aid of Dr George F. Keiper, Lafayette, councilor for the Tenth District, and the following officers were elected: President, Dr. Clark Cook, Fowler; vice-president, Dr. Samuel C. Fenton, Boswell, and secretary treasurer, Dr. Carl N. McCaslin, Earl Park.

White County Medical Society.—Dr. George F. Keiper, Lafayette, councilor for the Tenth District, announces the reorganization of this society January 28 The following officers were elected President, Dr Robert J. Clark, Monticello, vice president, Dr James L Carr, Monon, secretary, Dr. John H. Reed, Monticello; treasurer, Dr. Madison T. Didlake, and Dr J P Cray, delegate to state society

Miami County Medical Society.—This society reorganized, September 25, and adopted the standard constitution and by laws, and on January 29 the annual election was held, with the following result: President. Dr. Jared Spooner, Peru; vice president, Dr Ellis H Andrews, Peru; secretary, Dr John L Tyler, Mexico, and treasurer, Dr James O Ward, Peru By vote of the society the president-elect was instructed to cast the entire vote of the society at the next meeting for the board of censors and the delegates to the state meeting.

## Mississippi

Newton County Medical Association.—This society held its first regular meeting at Decatur, January 12, at which it adopted the standard constitution and by-laws, and elected Drs. Clarence V. Gilmore, Hickory, M. Luther Camp, Chunkeys Station, and Albert G. Petty, Conchatta, censors; Drs. M. Luther Camp, Chunkeys Station, W S Norris, Stamper, and I W Cooper, committee on health and legislation, and Dr W S Norris, Stamper, delegate to the state association

## Ohio.

Hancock County Medical Society.—Dr. Frank D. Bain, Kenton, councilor for the Third District, met the members of this society at Findlay, January 21, and delivered an address on the benefits of reorganization on the standard plan Dr Myron J. Ewing presided, and Dr John M Firmin acted as secretary A resolution to reorganize was adopted and a committee, consisting of Drs John M Firmin, Joseph P Baker and John C Tritch, was appointed to draft a constitution and by-laws

# Society Proceedings.

## MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*Ninety-Eighth Annual Meeting, held in Albany, Jan. 26-28, 1904.*

*(Concluded from page 391.)*

One of the valuable features of the scientific sessions was the symposium on abdominal pain.

### Abdominal Pain in General.

Dr. John H. Musser, Philadelphia, presented the opening paper. He said that while muscular rigidity or spasm was rightly held in high esteem as an indication of abdominal pain, certain precautions must be observed in interpreting this sign. In women, with relaxed and distended abdominal walls, there was not likely to be much muscular rigidity even in the presence of pain; also if there was much toxemia present. On the other hand, very muscular persons were apt to show this rigidity out of all proportion to the severity of the pain. The occurrence of rheumatism of the diaphragm and of diaphragmatic pleurisy should be kept in mind; also the fact that pneumonia, especially in children, might be confounded with appendicitis. Pyloric spasm and gastralgia were very apt to be mistaken for cholelithiasis. A sudden disappearance of pain was significant of the presence of a grave toxemia.

Dr. Joseph D. Bryant, New York, read a paper on "Abdominal Pain Referable to the Abdominal Walls." He said one should bear in mind the nerve distribution to the abdominal walls. An infection, localized in the abdominal wall itself, might be mistaken for intra-abdominal involvement.

### Abdominal Pain of Intestinal Origin.

Dr. Frederick Holme Wiggin, New York, said that, as a general rule, persistent and sharp abdominal pain pointed to peritonitis, and a dull, aching pain rather to involvement of the connective tissue. Tenesmus pointed to involvement of the lower third of the intestinal tract. If the colon were the offending part, there would usually be diarrhea, with a limitation of the pain and tenderness to the colon. The diagnosis of appendicitis should never be made until after disease of the chest had been excluded. In all cases of persistent and obscure abdominal pain exploratory operation should be done.

On the third day there was a symposium on nephritis.

### Renal Decapsulation from the Pathologist's Point of View.

Dr. J. M. Vancott, Brooklyn, concluded that decapsulation could only be injurious to the normal kidney, and of no benefit to the large white kidney.

### Surgical Treatment of Nephritis.

Dr. Willis G. MacDonald, Albany, thought that in infectious nephritis arising from local bacterial infection by such organisms as the gonococcus and streptococcus, and in cases of acute suppression of urine following operations on the genito-urinary tract, surgical treatment was of value.

### General Treatment of Nephritis.

Dr. Beverley Robinson, New York, treated in this paper only of acute and chronic diffuse nephritis. He said that, in the acute attacks, the patient should at once be placed in bed, clothed in woolen and surrounded by blankets, and given at first an almost exclusively milk diet. The kidneys should be relieved by rapidly emptying the bowel with salines, and by diaphoresis by the hot wet pack, which was simpler and safer than the hot water bath. Poultices over the kidneys to relieve the renal congestion, and high rectal irrigations of saline solution with Kemp's tube to promote diuresis, were useful. He looked on pilocarpin as a dangerous drug. If an attack of uremia were imminent, nitroglycerin or the sweet spirits of niter, and, in some instances, wet cupping or even venesection might be required. As the acute stage passed off, the dietary should be cautiously enlarged, and the pronounced anemia should be combated by the administration of the tincture of the chlorid of iron, or by Basham's mixture. The bowel and skin should be kept active, and excesses in eating or physical exercise carefully guarded against. The diarrhea of chronic Bright's disease was sometimes controlled by prolonged irrigation of the bowel. When there was so much anasarca that the skin became very tense, it might be necessary to puncture the skin, or even insert a capillary drainage tube. If dyspnea were marked, paracentesis of the pleura or abdomen might be demanded. Digitalis was often useful, but in persons past middle life, it was generally necessary to counteract its constricting action on the blood vessels by adding nitroglycerin. In chronic nephritis, one should be especially solicitous about the development of subacute attacks. The urine should be watched, and the diet and exercise regulated by the amount of albumin and the number and character of the casts found therein. Iodid of potassium was very prone to derange the stomach and impair the appetite. All irritant drugs, such as chlorate of potash, the salicylates and the phenol compounds should be used with caution. As a general rule, patients did better without alcoholics in any form, but there were exceptions, notably those who had been accustomed to small quantities daily for years. In nephritis and threatening or actually developed uremia, a good general rule was to give morphin only when the pupil showed a tendency to dilate; when the opposite condition obtained morphin was especially dangerous. For sleeplessness, bromids should be given.

### Discussion on Nephritis.

Dr. DeLancey Rochester, Buffalo, said that he had found it an easy matter, even in the humblest homes, to give the hot air bath, and, in his hands, it had proved exceedingly efficient. He did not use pilocarpin in large doses, but when given in minute doses, by hypodermic injection, and immediately followed by the hot air bath, he had found it useful in persons in whom it was not easy to excite free diaphoresis. As a guide to the management of chronic nephritis, it was just as important to determine from time to time the total excretory power of the kidney, as indicated by the total quantity of urea and of urinary solids, as it was to note the fluctuations in the albumin and casts.

Dr. S. B. Ward, Albany, urged the use of arsenic in overcoming the anemia of nephritis.

### Fifteen Years' Experience with Uterine Fibroids.

Dr. W. E. Ford, Utica, presented an experience embracing 162 cases which had been kept under observation for a sufficient length of time. There were 96 cases treated by the galvanic current in the earlier years. In 7 of these there was a disappearance of both the symptoms and the tumor, and 26 cases had been greatly improved for a period of five years or more. Thirty-one cases were treated by curettage, ligation of the uterine arteries or by the administration of drugs. Of this number, 24 had been temporarily benefited. There were 81 operative cases, 34 by Baer's method. He did not think more than 20 per cent. of cases of fibroids required operation.

### Results in Diffuse Septic Peritonitis Treated by the Elevated Head and Trunk Position.

Dr. Russell S. Fowler, Brooklyn, reported about 80 cases treated by this postural method, and about one hundred cases altogether were operated on, no one being refused operation, no matter how desperate the outlook. Of the 33 deaths, 17 occurred in the first twenty-four hours, and these patients were profoundly septic at the time of operating. Sixty-seven patients recovered. The technic consisted in applying to all infected areas a mixture of equal parts of peroxid of hydrogen and soda solution, and following this with salt solution. The entire abdomen and pelvis were flushed with the saline solution, and a glass tube inserted into the pelvis. Immediately after the operation the bed was elevated at least one foot.

Other papers read were as follows:

"A Study of the Climate of Long Island," by Dr. W. H. Ross, Brentwood, Long Island, N. Y.; "The Submerged Tonsil," by Dr. Thomas J. Harris, New York; "Irritability of the Bladder in Women," by Dr. R. L. Dickinson, Brooklyn; "Tic Douloureux and Other Neuralgias from Intranasal and Excessive Accessory Sinus Pressures," by Dr. Sargent F. Snow, Syracuse, reporting 20 chronic cases, none of which required excision of the nerve, but all of which showed intranasal pressures or collections in the sinuses; "Enuresis," by Dr. George E. Beilby of the State Industrial School at Rochester; "The Non-operative Treatment of Trachoma," by Dr. Frank J. Parker, New York, recommending vigorously rubbing the lids three times a week with a 1 to 500 bichlorid of mercury solution and having the patient at home drop into the eyes, night and morning, a solution of argyrol.

---

## Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### La Grippe.

In the general treatment of la grippe, Dr. D. R. Brower suggests that the patient be given the mild chlorid of mercury grains three to five (.20-.30) in divided doses, followed by a saline cathartic. To combat the infection, temperature and pain, he recommends the following combination:

℞. Salol
Quin. sulphatis
Acetanilidi, āā....................gr. xx 1|30
M. Ft. cap. No. xx. Sig.: One every hour or two hours.

The patient should be put to bed and placed on a light liquid diet.

When insomnia is present, as is the case quite frequently, he recommends the following:

℞. Trional ..........................ʒiss 6|
M. Ft. chart. No. vi. Sig.: One at bedtime, and repeat in one hour if necessary; or:
℞. Chloratis hydratis ..................ʒiss 6|
M. Ft. chart. No. vi. Sig.: One powder at bedtime dissolved in half a glass of water.

The after-treatment should be carefully carried out in order to build up the physical condition as rapidly as possible. He notes in this connection the increase in suicides and tendency to kidney changes following epidemics of la grippe. He therefore recommends in these convalescent cases a mild alterative similar to the following:

℞. Auri et sodii chloridi ............gr. iii-v |20-.30
Pulv. res. guaiaci.....................ʒi 4|
M. Ft. cap. No. xxx. Sig.: One capsule one-half hour before each meal, washed down with hot water.

In some cases the following is recommended:

℞. Ammon. brom. ......................gr. ʒii 8|
Ammon. iodidi.........................ʒi 4|
Ext. glycyrrhizæ flu. q. s. ad..........℥iii 90|
M. Sig.: One teaspoonful every three hours.

As a hematinic he recommends the following:

℞. Ferri sulph. (exsic.)
Sodii carb., āā.........................ʒi 4|
Ext. nucis vom.......................gr. vi |30
Acidi arsenosi.......................gr. i |06
M. Ft. cap. No. xxx. Sig.: One capsule three times a day after meals.

To relieve the laryngotracheal cough in influenza Yeo recommends the following combination containing apomorphin:

℞. Apomorphinæ hydrochlor. ............gr. i |06
Morphinæ hydrochlor.................gr. ¾ |05
Acidi hydrochlor. dil. ...............ʒss 2|
Syrupi ..............................ʒiv 15|
Aquæ q. s. ad........................℥iv 120|
M. Sig.: One or two teaspoonfuls at a dose and repeat as the individual case requires.

The following is also recommended to relieve the cough:

℞. Heroin hydrochlor. ..............gr. 1/24 |0025
Terpin hydratis ....................gr. iiss |15
M. Ft. pil. No. i. Sig.: One such pill at bedtime.

As an inhalation for the relief of the cough the following is of service:

℞. Glycerini
Spts. camphoræ, āā.....................ʒi 4|
Tinct. benzoini .......................ʒii 8|
Spts. chloroformi ......................℥ss 15|
M. Sig.: Thirty to sixty drops to be inhaled from a jug half full of hot water, two or three times daily.

The following, according to the author, is also valuable in relieving the cough:

℞. Liq. morph. hydrochlor.
Acidi hydrobrom. dil., āā...............ʒi 4|
Spts. chloroformi ....................m. iii |20
Tinct, limonis .........................ʒi 4|
Syrupi. q. s. ad.......................℥iss 45|
M. Sig.: One teaspoonful as indicated to relieve the cough.

In influenzal pneumonia the following is indicated:

℞. Ammonii carb. ........................ʒiv 15|
Tinct. cinchonæ ........................℥iss 45|
Spts. ammon. arom. .....................ʒiv 15|
Decoct. cinchonæ q. s. ad...............℥xii 360|
M. Sig.: Two tablespoonfuls with a tablespoonful of lemon juice in effervescence every four hours.

Where there are pulmonary complications the following formula recommended by H. C. Wood will be of value:

℞. Ammon. chloridi ......................ʒii 8|
Apomorph. hydrochlor. ...............gr. i |06
Mist. glycyrrhizæ comp. ...............℥iss 45|
Syrupi ................................℥iss 45|
M. Sig.: One dessertspoonful every two hours.

And if diarrhea occurs in the course of an influenzal attack he recommends the following combination:

℞. Bismuthi subnit. ....................gr. x |65
Acidi carbol. ......................gr. iss |09
M. Ft. cap. No. i. Sig.: One such capsule every two, three or four hours.

For the neuralgic pains in influenza Bardet, in *Clin Ther.*, recommends the following combination:

℞. Exalgin .........................gr. lxxv 5|
Tinct. aurantii .....................m. lxxv 5|
Syr. aurantii ..........................℥i 30|
Aq. destil. q. s. ad....................℥v 150|
M. By rubbing the tinctura aurantii and exalgin together, adding sufficient *alcohol* to dissolve, then add the syrup aurantii and water.

Sig.: One tablespoonful at a dose and repeat if necessary. [Exalgin is methyl-acetanilid.]

### Pertussis.

The following combinations, recommended by *Jour. des Pract.*, are of value in the treatment of whooping cough:

℞. Pulv. belladonnæ rad. ...........gr. 1/20 |003
Pulv. sacchari .........................ʒi 4|
M. Ft. chart. No. viii. Sig.: Two powders daily; or:
℞. Atropinæ sulph. ................gr. 1/100 |0006
Aquæ destil. ...........................℥vi 180|
M. Sig.: One dessertspoonful at a dose and repeat in three or four hours, watching the effects carefully; or:
℞. Bromoform. ......................m. xlviii 3|20
Alcoholis .............................ʒiiss 10|
Aq. laurocerasi ........................ʒi 4|
Aq. destil. ...........................℥iv 120|
M. Sig.: One teaspoonful four times daily; or:
℞. Bromoform.........................m. xlviii 3|20
Olei amygdalæ dulcis
Pulv. acaciæ, āā.......................℥ss 15|
Aq. laurocerasi ........................ʒi 4|
Aq. destil. q. s. ad...................℥iv 120|
M. Sig.: One teaspoonful three or four times daily.

[When administering bromoform the effects must be carefully watched on account of its tendency in some cases to produce depressing effects.]

### Tapeworm in Children.

The following outline of treatment is of service as a vermifuge in children, according to an abstract in *N. Y. and Phila.*

*Med. Jour.*: Place the child on a milk diet for two days. The night before administering the vermifuge give a purgative enema of sodium sulphate. The following morning give:

| | | | |
|---|---|---|---|
| ℞. | Oleores. aspidii | m. xxx-ʒiss | 2.-6 |
| | Hydrarg. chloridi mitis | gr. iii-viiss | 20-.50 |
| | Pulv. saccharo | ʒvi | 24 |
| | Gelatin q. s. | | |

M. Sig.: To be given in four doses at intervals of half an hour. While the worm is being expelled, another purgative enema may be given, if the parasite threatens to break.

### Subacute Gout.

The following combination is recommended by *The Pract.* in the treatment of subacute gout:

| | | | |
|---|---|---|---|
| ℞. | Colchicin | gr. 1/60 | 0001 |
| | Ext. nucis vom. | gr. 1/4 | 015 |
| | Ext. gentianæ | gr. i | 06 |

M. Ft. pil. No. i. Sig.: One such pill three times a day.

As a local application for gouty joints the following is recommended by Clemens in *Amer. Med.*:

| | | | |
|---|---|---|---|
| ℞. | Sodii carb. | ʒiii | 12 |
| | Tinct. opii | ℥ii | 60 |
| | Linimenti bellad. | ℥ii | 60 |
| | Aquæ q. s. ad | ℥viii | 240 |

M. Ft. linimentum. Sig.: Mix with equal parts of hot water and apply locally to the affected joint on a cloth and cover with oiled silk.

## Medicolegal.

**Medical Examiner's Decision not Final.**—The Supreme Court of Nebraska holds, in C., B. & Q. R. R. Co. vs. Olson, that the decision of the medical examiner of the relief department of a railroad company that a member is "not entitled to any further disability benefits" is a mere conclusion, and is not binding on the parties.

**Can Not Compel Witness to Exhibit Leg—Compensation.**—In the case of McKnight vs. Detroit & Mackinac Ry. Co., brought to recover for medical and surgical services rendered to a number of persons injured in a train wreck, one of those treated was called as a witness for the railway company and asked to exhibit his leg to the jury. This he declined to do, and the trial court refused to compel him to do so. The Supreme Court of Michigan holds that this ruling was correct. It distinguishes this case from one where the question was whether a party to an action could be required to submit her arm at the point of an alleged fracture, where such exhibition would cause no shock to the sense of delicacy, in which the decision was rested on the ground that, where a person appeals for justice, he impliedly agrees in advance to make any disclosure that may be necessary to be made in order that justice may be done. It says that this witness occupied no such relation to the cause, and objected to exhibiting his leg, and the Circuit Court correctly ruled that he had the right to so object. It was requested that the jury be instructed, in effect, that there were no amounts agreed on with the railway company for the services performed or to be performed, and that, if it was liable at all for any professional services rendered, it was liable only in such an amount as would be reasonable and fair under all the circumstances; that the party suing had not the right to fix an arbitrary fee, nor could any number of physicians agree on a fee to be charged. They were entitled to receive, if anything, what their professional services were worth in the community in which they rendered them, and no more. The circuit judge charged the jury, in substance, that, in estimating the value of the physician's services, they should consider the professional skill and the experience of the physician, the nature and character of the services rendered, the difficulties and the nature of the case, and the amount of services rendered, and clearly limited the recovery to such a sum as, on the evidence, the jury should find would compensate the party suing for services rendered in this case. The Supreme Court thinks this sufficiently covered all that the company by its request had the right to have given to the jury. It says that it necessarily excluded the fact that an arbitrary fee might be fixed by the party suing or by any number of physicians; and, had the request been given, it might have led the jury to believe that the purpose was to discredit the testimony of the witnesses for the party suing who were physicians, and who had substantially agreed as to the value of his services. Another physician, who was called as a witness for the company, having testified that he, too, had attended a number of victims of the wreck, the Supreme Court holds that there was no error in excluding evidence of what he received for his services. It says that he was permitted to testify fully as to the reasonableness of the charges of the party suing, and evidence of what he received for the services he rendered would have opened the question as to how his services compared with those of the party suing, and would have involved the trial of an additional case.

**Liability for X-Ray Burn—Competent Witnesses.**—The Supreme Court of Minnesota holds, in Henslin vs. Wheaton and others, that, in an action against a physician and surgeon for negligence and unskillfulness in applying to the body of the party suing the device known as "Roentgen's X-rays" for the purpose of locating a foreign substance thought to be in his lungs, the rule of liability is the same as that applied in other actions for malpractice, and one of ordinary care and prudence. It says that this was the first case to come before it involving alleged negligence on the part of physicians in applying the recently-discovered *x*-rays, and that no rule of care in such cases had been laid down. But there can be no doubt that the rule applicable to the care and skill required of physicians toward their patients in other cases applies. That rule was stated in Martin vs. Courtney, 87 Minn. 197, in the following language: "The legal obligation of the physician to his patient, where his conduct is questioned in an action of this character, demands of him no more than the exercise of such reasonable care and skill as is usually given by physicians and surgeons in good standing." The rule is one of ordinary care and prudence, and the question presented in this *x*-ray case was whether the evidence received and that offered on the trial tended to show a failure on the part of the parties sued to exercise such care. The party suing testified that the exposure of his person to the *x*-rays was made for too long a period of time, and that the tube or bulb through which the rays are generated was placed too close to his body. He testified to the number of times the *x*-rays were applied, and the length of time--from thirty to forty minutes on each occasion—and that the tube of the apparatus was placed within two inches of his person in each instance, except one. He then called as an expert witness one whose testimony, if received, would have tended to show unskillfulness and negligence on the part of the parties sued. The foundation was fully laid for his opinion as an expert touching the questions involved in the case. But he was not a physician and surgeon, and the parties sued raised the objection that he was incompetent to testify against them, under the rule announced in the case of Martin vs. Courtney, 75 Minn. 255, where it was held that, in an action against a physician or surgeon for malpractice—unskillfulness in treatment being charged—the physician was entitled to have the propriety of his treatment tested by physicians of the same school. The trial court applied that rule to this case, and in doing so the Supreme Court is of the opinion that it erred. The Supreme Court says that the application of the *x*-ray to the party suing was not for the purpose of treating any disease or ailment from which he suffered, but for the purpose of locating, if possible, a foreign substance thought to be in his lungs (the gold crown of one of his teeth, which he thought he had inhaled). While it, perhaps, may in some instances be used as a remedial agent, it was not so employed in this case. The so-called *x*-rays, discovered by Roentgen, have been recognized and known to scientists, both in and out of the medical profession, for some eight years. During this time the apparatus for the generation of the *x*-rays, together with the fluoroscope, has been used very generally by electricians, professors of physics, skiagraphers, physicians, and others for experimental and demonstrative purposes. It is a scientific and mechanical appliance, the operation of which is the same in the hands of the college professor, or the physician of the allopathic, homeopathic, or any other school of medicine. It may be applied by any person possessing the requisite scientific knowledge of its properties, and there would seem to be no reason why its application to the human body may not be explained by any person who understands it. The rule in the Courtney case could therefore have no application to the case at bar. It might apply, did it appear that the application of the *x*-rays to the person of the party suing was for medical purposes, and not for the scientific purpose of discovering the presence of a foreign substance in his lungs. Wherefore, a physician who applies the *x*-rays, not for medical purposes, but to locate a foreign substance in the body of his patient, is not entitled to have the question of his care and skill in applying it determined by the opinions of physicians of his own school.

7 The Relationship Existing Between the Ophthalmologist, Otologist and the General Hospital. Frank Allport.

1. **Gallstones.**—Stern remarks on the sudden appearance of pain, the difficulties of differential diagnosis, especially from appendicitis when the appendix points upward, and from right-sided floating kidney. As regards the appendix it is fortunate that the same treatment is required for both the conditions In floating kidney the most important point in the differential diagnosis, according to Kehr, is the sensation which is experienced with the reposition of the floating kidney. It darts upward and backward with a flop, and is liable to remain in its new position, while the gall bladder constantly returns to its place close to the anterior wall of the abdomen. No error should ever occur in cholelithiasis when a tumor exists in the right hypochondrium whose form and movement are inherent to a distended gall bladder. Jaundice is one of the least frequent symptoms, and is probably a disease of the individual liver cell communicated by extension of an inflammatory invasion from the biliary passages or some affection of the liver *per se*, unaccompanied by obstruction. Adhesions or kinks may produce symptoms in a patient who has already passed the stone. Stern gives a classification in detail of some 12 different types of gallstone disease. He remarks that the persistent latent stage is, of course, the best cure compatible with the existence of gallstones. There are two methods of procedure: to produce a stage of quiescence and latency, and operation. No solvent is known, and there is no remedy that will drive stones from the bladder. It is an unquestionable fact that, with the faithful use of hot laxative waters, the circulation of the liver, portal system and entire abdomen is improved, especially where the patient has been living an idle, luxurious life. Riedel says that 95 per cent. of all gallstone disease passes into the latent stage, and only 5 per cent. calls for operation. It should be the last resort. Stern says the physician can call himself a good diagnostician when he is able to differentiate between hydrops and empyema of the gall bladder, and acute seropurulent cholecystitis, and when he can determine whether a chain of symptoms is dependent on obstruction by stone or due to pressure by a tumor. This skill should be possessed by every practitioner.

2. **Auto-Abortion.**—Cumston discusses the possibility of auto-abortion, and thinks that it is comparatively common and is much more practicable than has been alleged by the textbooks. He gives his reasons for this belief in detail.

3. **Postoperative Intestinal Obstruction.**—Pond classifies postoperative intestinal obstruction as due to, 1, impairment of the physiologic function; 2, pathologic processes such as inflammation; 3, mechanical obstruction due to adhesion, adventitious bands, omental rents, accidents to the sutured wall and the presence of foreign bodies. Byford's plan of giving a mild laxative before the anesthesia is good. It will not act as a cathartic, but as a general intestinal tonic and stimulant, and in the vast majority of cases is most gratifying in its action, preventing impaction and inertia of the bowel. The temptation is great to be too energetic, however, in attempts to produce peristalsis. Obstruction due to lowered resistance can in a great measure, like paresis, be avoided by carefully conducting the operative procedures, avoiding hemorrhage, etc., and much of the tonicity can be restored by filling the abdomen with a hot solution of adrenalin chlorid in decinormal salt solution in the proportion of 1 to 1,000, which increases the intestinal blood pressure very markedly and stimulates intestinal peristalsis. Intestinal atony, due to predisposing causes, is the most obstinate form. The impairment due to pathologic process is most commonly met with in acute inflammatory involvement of the intestinal coats. When the process involves all the tunics the condition is exaggerated and cathartics must be withheld; the impaired intestine must have rest. If tenesmus be present the large bowel is involved, and the use of oxygen gas will relieve the circulatory stasis, and reestablish peristalsis. If the trouble is in the small intestine withhold all food and drink by the mouth and feed per rectum predigested food. Tympany and distension can often be controlled by gastric lavage as often as the patient needs it. Acute septic peritonitis may be caused by obstruction of the bowel from the absorption of septic material, and better results have been obtained by a high enema containing magnesium sulphate and turpentine than by evacuants administered by the mouth. The treatment of postoperative obstruction, of course, depends on its cause. An enema, medicated or plain, is the best first resort. If it does not prove effectual the application of the cautery over the abdomen should be tried. The use of cathartics is dubious, but rest does much in this condition. Atropin is said to act as a sedative, relieving the stasis. In mechanical obstruction the only thing to do is to operate, the earlier the better.

12 *Public Health and Food Preservatives. (Concluded.) R. G. Eccles.

8.—See abstract in The Journal, Feb. 6, p. 389.

10. **Fused Kidney.**—The various types of fused kidney are noted by Dennis, who reports a case and sums up the data in regard to the subject as follows:

1. According to available statistics, complete absence or extreme atrophy of one kidney is found once in 2,630 cases; horseshoe kidney once in 1,000 cases; and the fused kidney, exclusive of the horseshoe variety, once in about 16,000 cases.
2. The great majority of fused kidneys are misplaced, being usually in the median line and lower than normal.
3. The completely fused kidney, with normal position and approximately normal outline, is the rarest form of all.
4. Cystoscopic examination, with catheterization of the ureters, will prevent the error of removing the only organ present in all cases, except those of fusion.
5. Horseshoe and irregularly fused kidneys may be recognized on exposure by their abnormal shape or position, or by both.
6. The single remaining and rarest variety, that with normal outline and *position*, can probably always be at least suspected and left, if the ureter and pelvis are found shifted *to the* anterior surface.

11. **Tuberculosis.**—Maher reports here further experiments with his antitubercle X bacillus on rabbits previously inoculated with the tubercle bacillus and the results, and also discusses rather briefly other experiences in regard to the antagonistic action of other germs on the tubercle microbe. He says,

in substance, that he would like to emphasize the following points: The X bacillus can be injected alive and in pure culture into the human system. 2. After its injection it remains alive in the human body often for weeks, and does no other harm than occasionally, for obscure reasons, causing slight suppuration at the point of injection. 3. After its injection it causes a variable febrile reaction, never serious, and which probably varies in intensity according to the amount of its enzymes that are injected with the bacillus or according to the amount of material it finds to feed on. 4. After its injection, it has been found in the urine and blood and sputa of persons injected. 5. After injection into the groins of persons suffering from tuberculosis there is often a subjective sense of local reaction at the site of the tuberculous lesion. 6. After its injection into the connective tissue about tuberculous *fistulæ in ano*, a marked improvement, even to closure of the fistula, has followed. 7. After its injection into the ear of persons suffering from tuberculosis otitis media no harm has ensued, but in several instances a cure has followed. 8. After its application on gauze or cotton packing to sinuses leading from carious bone, supposedly tuberculous, such sinuses and caries have healed with surprising promptness. 9. Its hypodermic injection into patients suffering from lung tuberculosis has been followed in many instances by marked relief of cough, fever, night sweats, wasting, anorexia, diarrhea and hemorrhage. 10. Its instillation into the open tuberculous pleural cavity has caused the drying up of a purulent discharge that was resistant to ordinary methods. 11. Its hypodermic injection into consumptive patients has in several demonstrable cases been followed by the apparent cure of the disease. 12. As a valuable scavenger of the tuberculous human system, the X bacillus claims the interest of the medical profession for the further reasons that it grows in acid or alkaline media, that its product is alkaline, that it grows in the presence or absence of air, that it feeds only on *dead matter*, that it grows more quickly and has more vitality than the ordinary pus-producing germs, and reduces their number markedly after its introduction into the human system. 13. Some as yet incomplete investigations would seem to show that this X bacillus is not without beneficial effect on other than tuberculous invasion. While he thinks that many of his statements need further confirmation by better bacteriologists, and that probably some of them may fail of such confirmation, still he thought it was time to call the attention of the profession to his subject.

12. **Food Preservatives.**—Eccles further argues against the existence of the alleged dangers of salicylic acid. He quotes authorities showing that its presence in food products in quantities required for their preservation is likely to be innocuous, and assumes that the probable reason for its having such a slight effect is its rapid elimination. He also goes at length into the economic advantages of the use of salicylic acid as a food preservative.

### Boston Medical and Surgical Journal.

*January 28.*

13 *Experiments with the McGraw Elastic Ligature. Fred T. Murphy.
14 *Differential Diagnosis of Rheumatism and Arthritis. Thomas F. Harrington.

13. **The McGraw Elastic Ligature.**—Murphy gives the history of this method, crediting its earliest use to Gaston. McGraw brought out his results independently in 1891, and his communication has since been followed by various clinical and experimental confirmations of his claims. Murphy reports experiments which show that a successful anastomosis between the stomach and intestine or between two loops of the intestine is possible by this means, but it is not applicable when an immediate opening is required. The time of cut-out varies, depending on the character of the ligature, the method of application, and the resistance of the tissues in any case, but ultimately the ligature will cut out. A knot at either end of the elastic loop increases the rapidity of its action, and the penetrating of the gut by the ligature seems to cause no bad symptoms. The serous surface on the outside of the joint when completed is smooth. The anastomosis, by gross or microscopic examination, shows no evidence why there should be any greater tendency to contraction of the opening than with the ordinary methods of intestinal suture. The operative risk is minimized both as regards shock and infection. Adhesions across the opening are possible, but rare. Murphy concludes that in cases where immediate opening of the bowel is not imperative, and where the avoidance of operative shock is an important factor, the ligature may prove to be the operation of choice in gastro-enterostomy and lateral anastomosis. The article is profusely illustrated.

14. **Rheumatism and Arthritis.**—Harrington classifies the various forms of arthritis into seven species: infective deformans, osteo-arthritis, traumatic, gouty, hemophilic and senile. The diagnosis is discussed at length. Arthritis deformans is considered a good descriptive term, and is credited to some nerve disturbance for its origin. The form described by English observers as acute rheumatoid arthritis confounds acute rheumatism and arthritis deformans more than any other affection. Osteo-arthritis may start from any cause or have no ascertainable cause. The condition is a chronic one, usually affects the large joints, often unilateral, more common in men, especially old men, and tends to the enlargement of bony, not cartilaginous matter as in arthritis deformans. Any manipulation of the joint is liable to break off some of the osteophytes, while in arthritis deformans there is a false ankylosis amenable to proper manipulation. The form of osteo-arthritis occurring in the spine—spondylitis—he thinks is more common than supposed, and may produce peripheral paralysis, rarely equal on the two sides. In traumatic arthritis the history is important. Gouty arthritis has the gouty characteristics of sudden onset, and the presence of deposits in the ear, while it usually attacks single small joints. Hemophilic arthritis should be kept in mind, especially in surgical cases. It does not seem to be due to trauma, and usually occurs between the fourth and sixth years, most often in the male, generally affecting the knee and elbow. The mortality among hemophilics having arthritis is less than among the others. In senile arthritis there is a thickening of the capsule, but not of the bones; it has no relation to rheumatism, and is more stiffness than soreness. It does not involve the heart, and grows better as the day progresses.

20 Scarlatinal Panotitis; Exfoliation of a Portion of the Labyrinth; Radical Operation. Carl Koller.
21 An Unusual Case of Potassium Iodid Idiosyncrasy. Henry Gathmann.

15. **Plague in Manila.**—Plague in the Philippines seems to have effected a lodgement only in Manila, and is there largely confined to the Chinese population. Munson gives statistics of, from Jan. 1, 1900, to Sept. 1, 1903, 970 cases with 812 deaths—a mortality of 83.8 per cent. Certain districts of the city seem to be almost free from it, owing to the local conditions. The mortality was decidedly less among Americans than among other classes, Europeans surpassing them in this respect. The Chinese are ahead of the Filipinos who, however, furnished a considerable proportion of cases, although but a small percentage of their total population. The disease is about six times as likely to occur in males as females, though among the Filipinos more women than men suffer. The methods of meeting the conditions are described, and seem to be very efficient. Protective inoculation has also been employed of late and demonstrated its advantages.

17. **Tabes.**—Hassin reviews the theories of tabes, showing that several of the more recent ones, such as those of Marie and Nageotte, point to the theory of Obersteiner-Redlich, which he adopts, namely, that the membranes of the cord are involved and the columnar lesion is secondary.

18. **Antiseptic Toilet.**—Stewart maintains that chlorin is the best hand disinfectant known, and gives the results of numerous culture experiments after its use. The fluid he recommends is in use in the New York Polyclinic Hospital and the City Hospital. The method used is five minutes' mechanical cleansing with powdered pumice stone, sterile hot water, green soap and wooden nail cleaners, followed by five minutes' chemical cleansing with two heaping teaspoonsfuls of fresh 35 per cent. calx chlorata and 1 teaspoonful of U. S. P. (36 per cent.) acetic acid to a pint of sterile water. If this stands for ten minutes without stirring, the necessary chemical changes are complete. He himself omits the green soap, and proceeds as follows: He takes one teaspoonful each of lime and one of powdered pumice stone on a saucer with wooden nail cleaners. He has further a basin with two quarts of "cool" water mixed with one teaspoonful each of calx chlorata, of table salt, aqua ammoniæ and carbonate of potassium. In this basin is a nail brush. He dips his hands in this solution, takes the wooden nail cleaner and applies the pumice under and around the nails. If he can not get them speckless, he then dips the wet ends into the chlorid on the saucer. He avoids getting lime on the sensitive skin, but he works it under the finger nails with the stick and with the pumice so that it gets into every possible crevice. Then he scrubs his hands, including nails, in the solution with the brush. This is the five-minute mechanical preliminary, followed by the chemical as above described. He finds that in many cases the mechanical treatment leaves the hands sterile without the subsequent chemical treatment. Clinical experience has shown that the solution originally recommended was unnecessarily strong, and he suggests the use of one teaspoonful of acetic acid and 2 of lime to the pint of sterile water. For sterilizing the vulva he uses a one-third strength, as also for compresses on sterile wounds.

19. **Abortion Instruments.**—Griffith relates his discovery of the peddling of instruments for abortion in Paris, and describes and illustrates the instruments. It would seem that local physicians knew very little about it.

25 *Notes on the Widal Reaction: 1. The Question of Dilution. 2. The Influence of Jaundice. E. Libman.
26 *A Brief Note on the X-ray Treatment of Glandular Tuberculosis. Frank P. Vale.

22. **Irregular Practitioners.**—The essentials for the successful prosecution of illegal practitioners are, according to Mayer, the definition of the practice of medicine, abolition of minimum punishments and the devising of some method whereby all advertisements of irregular practitioners can be eliminated from the newspapers that are published in the state.

23. **Intestinal Anastomosis.**—The method here described by Keefe begins by severing the to-be-resected portion of the intestine from the remainder by the electrothermic angiotribe. and cutting through the desiccated strips left by the angiotribe. The desiccated ends are then united with a modified and an interrupted Lembert suture. He gives the details, and asserts that the results are immediate hemostasis, perfect asepsis, no intestinal obstruction, no eversion of mucous membrane, little danger of cicatricial stenosis, a firm strong union, and rapid operation. He has operated on dogs by this method, but in only one human case. In this the postmortem showed good union.

25. **The Widal Reaction.**—Libman has examined 1,500 cases of fever, 550 of which were typhoid. In the 950 non-typhoid cases the Widal reaction was never reported positive even with a dilution of 1 to 20. While it is possible that there were some cases of paracolon infection in the 550 cases, and the agglutination at a dilution of 1 to 20 may have been simply a group-agglutination, the mistake is not a serious one, for to the clinician a case of paratyphoid fever is to be considered and handled, at least for the present, as one of typhoid. He asks why we use the dilution of 1 to 50 when we get such reliable results with 1 to 20. He has been surprised to find in some cases a positive result with the weaker dilution while it was either negative or not clearly positive with the stronger one. He thinks this is explainable by the fact that in the dilution of 1 to 20 the lytic action of the serum is so marked that one can not obtain a clear picture, and he thinks that in performing the agglutination test it is best to use both strengths, the 1 to 20 and 1 to 50, and it is even possible that the 1 to 100 or even higher dilutions may be positive when the lower ones are negative. The second point mentioned is the reaction in icterus cases. He has made a number of experiments with the bile and serum of jaundice patients with the result that he finds nothing to convince him that jaundice *per se* can cause the positive Widal reaction. All that can be said is that while icteric serum may at times be possessed of a certain amount of agglutinating power, there is at present no definite proof that it can produce sufficient agglutination to interfere with the clinical diagnosis.

26. **X-Ray Treatment of Glandular Tuberculosis.**—Vale finds but little literature on this subject. The most satisfactory statements are in Pusey and Caldwell's work where five cases are reported with marked reduction in the size of the glands. In one, complete disappearance occurred. He reports a case where strikingly good results followed *x*-ray treatment. At present the patient is practically well. Encouraged by the results, he used it in one other case where the lungs were affected secondary to tuberculous processes in the cervical glands. The lungs were improved at the Saranac Sanitarium, but the glands had increased in size. Their removal had been thought of, but advised against for fear of bringing the tuberculous process in the lungs into renewed activity. During the short period of treatment of two weeks, they diminished appreciably in size, and a few weeks later the patient wrote that they were hardly half as large as before.

27 Primary Lateral Sclerosis. F. W. Langdon.
28 *Macewen's Method in Amputation of the Hip. H. D. Hinckley.
29 Nasal Polypus. Dudley S. Reynolds.

28. **Amputation at the Hip-Joint.**—Of the various methods Hinckley prefers the Macewen method. The assistant, standing on the left side, places his right closed fist on the abdomen of the patient so that his first knuckle touches the upper and left border of the umbilicus. He then presses downward and toward the median line, compressing the aorta just above its bifurcation against the spinal column. If of short stature, he should stand on a stool so that he can bring his whole weight on the abdomen. This cuts off all the circulation of the affected part so that no instrumental equipment is required. The means are always at hand, and the assistant is out of the way of the operator and his other assistants. It is easy to determine the effectiveness of the compression by feeling the pulse in the common femoral of the sound side. Finally, the field of operation being unincumbered, the surgeon can operate as rapidly as he is able and form his flaps to suit his case. The embarrassment of respiration which has been given as an objection to the procedure is too temporary to be of serious import, but there may be some difficulty in obese patients. Hinckley reports a case in which this method was employed, without the loss of a drop of arterial blood, with perfect success.

32 Treatment of Malarial Fever. T. Atchison Fraser.
33 Tetanus in Newborn Infants. R. B. Gilbert.
34 *Transmissibility of Diseases of Animals to Animals of Other Species. Geo. T. McWhorter.

34. **Animal Diseases.**—McWhorter discusses anthrax, glanders, hydrophobia, swine plague, tuberculosis and the bites of

venomous serpents. He concludes that the evidence shows that certain diseases of animals are transmitted from species to species without diminution of virulence. Animal life being considered cheap, the source of infection in these cases is soon eradicated and the total of human fatalities from it is not great. Other diseases of animals, such as vaccinia, are often communicated to man, mild in character and protective in influence, as are certain human diseases communicated to animals. A number of diseases of animals are transmissible to other species only with the utmost difficulty or not at all, and the parasitic carriers of the disease may be able to infect only that species from which they receive infection. Species is a great and but little understood factor in the distribution of disease. Heterolysis rather than autolysis or isolysis must be largely relied on in immunization.

35 *Considerations Relative to Gastric Surgery: A Plea for Early Accurate Diagnosis. T. W. Huntington.
36 *The Treatment of Chronic Heart and Arterial Diseases by Means of Baths and Gymnastics. Josef I. Manson.
37 A Case of Hodgkin's Disease with Relapsing Fever. J. O. Hirschfelder and W. R. P. Clarke.
38 Immediate Repair of the Lacerated Perineum. Henry J. Kreutzmann.
39 A Case of Molluscum Fibrosum. George B. Somers.

35. **Gastric Surgery.**—The point made by Huntington in regard to pyloric insufficiency, gastric hemorrhage, etc., is that in any case with obscure and persistent symptoms, a diagnostic incision should be asked for and insisted on before the patient is run down and when there is reasonable hope of recovery from the section, the anesthetic and the surgical shock. Recurrent hemorrhages from the stomach that are of sufficient magnitude and frequency to interfere with the patient's general well-being can be relieved by proper drainage of the ulcerated stomach. By the same means the stomach can be relieved from the distressing consequences of nonmalignant pyloric obstruction. He believes the time is not far off when the value of modern teaching regarding malignancy of the stomach will find expression in the uncovering of an incipient malignant nodule by means of a diagnostic incision and giving a chance of relief by surgical methods; that the diagnostic incision is thoroughly legitimate and an accredited procedure. It should be resorted to with the same freedom that is exercised in dealing with the stomach contents in the laboratory.

40 *Lumbar Puncture in (*a*) Otitis Serous Meningitis; (*b*) Cerebrospinal Form of Typhoid Fever, and (*c*) Cerebrospinal Meningitis. Francis Huber.
41 *Abscess of the Lung Following Acute Pneumonia. A Report of Two Cases. L. Emmett Holt.
42 *Some Cases of Infantile Nephritis. F. M. Fry and Charles F. Martin.
43 *St[illegible] San Francisco. (Streptococcus [illegible] Blum.

40. **Lumbar Puncture.**—Huber reports the effects of lumbar puncture in three separate conditions, in all with good results. His opinion of the therapeutic value of the operation is strengthened by these cases.

41. **Post-Pneumonic Lung Abscess.**—Two cases are reported by Holt, operated on by aspiration. Each case followed an acute pneumonia, the abscess being recognized about two and a half months after the attack. In the first case the child was under constant observation. In the other the history of the onset was definite. In both pneumococci were present in the pus, in one case associated with the staphylococcus. In neither were any tubercle bacilli found. The indications were that the abscess had been shut off from the bronchi by inflammation; otherwise there would have been more evidence of a mixed infection. No pus was coughed up either before or after the operation. The diagnosis of the condition is discussed, showing that the physical signs are not very characteristic, but other symptoms, such as continued fever and high leucocytosis, may aid in the diagnosis. From tuberculosis, differential diagnosis may be difficult and sometimes impossible without prolonged observation, but we should remember that abscess most frequently follows acute pneumonia; that the patient may have been previously in the best of health without any exposure to tuberculosis. Wasting is a less frequent symptom, and the absence of tubercle bacilli in the sputum, aspirating pus and the presence of pneumococci assist in the recognition. The treatment in the case reported was simple. As the pleural cavity is generally obliterated by dense adhesions, as in both these cases, incision into the lung can generally be made with little risk.

42. **Infantile Nephritis.**—Fry and Martin have examined 100 infants under three months of age as regards the urine. Albumin was present in 19 cases, and 17 had also casts, hyaline and granular. Out of 100 he found that 31 altogether had casts, 14 without albumin. Of these 31, 22 were bottle-fed and 9 breast-fed. Uric acid was present in 26 cases, 14 of them with albumin and casts. Of the 12 remaining, 10 had either albumin or casts. It would seem that where uric acid was in abundance only a very few—that is, 3—escaped some evidence of nephritis or renal irritation. Of these 26, 19 died. Autopsies were obtained on 7. In each of these there was uric acid infarcts and parenchymatous nephritis. Section showed degeneration of the convoluted tubules. In 3 of the cases there was also acute interstitial nephritis. There were 6 others that gave clinical evidence of nephritis. It would appear that marasmus was not the sole cause of the nephritis, but the marked increase of uric acid would indicate a possible association between the nephritis and marasmus.

43. **Streptococcus Gastro-enteritis.**—Blum describes cases observed by him in San Francisco during the hot season with symptoms of constipation followed by diarrhea, stools characterized by mucus and blood having a foul odor, fever of the remittent type, and general prostration. The cases were obstinate, but finally recovered under treatment with calomel, salol, bismuth and tannigen. A diet devoid of milk seemed to be better in these cases than when milk was given. Castor oil was administered at intervals of four or five days. There was evidence of infectiousness in one of the cases where the disease seemed to spread in the family. In all the cases where cultures were made streptococci were present, but in only one instance was it found in pure culture. He discusses the literature of the subject, and remarks that the diagnosis can only be made positive with the microscope. Bacillary gastroenteritis is usually a severe disease, and while Booker classifies streptococcus infection as the most virulent form, it is of interest to note that all these cases, though severer than the ordinary diarrheal disturbances, ran a comparatively benign course.

46 Vaginal Cystotomy for Stone in the Bladder. Charles R. Robins.
47 A Case of Condyloma Acuminata in an Infant. Richard R. Smith.
48 *Toxemia of Pregnancy. William S. Stone.

44. **Renal Calculus.**—Leonard illustrates the accuracy of the Roentgen rays in the diagnosis of renal calculus, and claims that the method is imperative in all suspicious cases. In any apparent attack of renal calculus no course of treatment can be undertaken without the determination of the presence or absence of stone, and the Roentgen rays should be used before every nephrolithotomy or ureterolithotomy to determine whether or not operation is necessary, and to localize and limit the operation itself, as well as to make it comprehensive and complete.

48. **The Toxemia of Pregnancy.**—Stone's principal topic is the hyperemesis of pregnancy which he attributes to a general toxemia. He classifies toxemia as mild and severe, and divides the latter into acute and subacute. The subacute includes those appearing in the early months, which after a duration of four to seven weeks terminate fatally or end in recovery: and a smaller proportion that also appear early but continue

throughout pregnancy with intervals of improvement, though likely to develop very serious conditions and even to be fatal. Of the acute types there are: 1, Cases of pernicious vomiting ending fatally in two weeks; 2, cases which, with or without previous manifestations of a mild character, suddenly become completely prostrated and die within a few hours; and 3, cases ordinarily described as eclampsia. He points to the difficulty of recognizing certain urinary changes until more improved methods of technic are generally available. The treatment on the hysterical theory is analogous to treatment of cancer by Eddyism. The drugs that are useful are few, such as calomel, salol, etc., and the absolute abstinence from either food or drink until improvement has commenced. Nutritive enemata, as well as stomach lavage, may sometimes be employed. The chief reliance, however, should be placed on injections of hot normal saline solution into the rectum at frequent intervals, according to the Behm method; it may be necessary to add half an ounce of whisky to some of the injections. In some cases it may even be advisable to employ continuous irrigation for half an hour every three or four hours, using the double current rectal tube or two separate tubes. Occasionally hypodermoclysis may have good effect. He would say that pregnancy ought to be interrupted before the appearance of black vomit or rise in the pulse or urinary changes. In the acute or fulminating type he thinks the matter of intervention is open to the most serious doubt.

56 A Fatal Case of Chorea Complicated by Endocarditis, Pericarditis and Nephritis Augustus A. Eshner.
57 Four Cases of Malignant Disease of the Lungs. J. C. Lange.

53. **The X-Rays.**—Kassabian classifies the results of his observations as to the effects of the *x*-rays in malignant disease as follows: 1. Class where total failure results as far as cure is concerned. 2. Class where there has been decided improvement of symptoms, alleviation of the pain from the beginning, disappearance of induration and edema, decrease in the size of the enlarged glands, the ulcerating surfaces taking on a healthy appearance, etc. 3. Cases that are totally and permanently cured; this class is small. Cases coming under this category are sarcoma, external carcinoma and epithelioma. Rodent ulcer requires the least trouble and the fewest applications. So far he has cured 16 cases without a single recurrence. It is not possible to say that recurrences will not occur, but four years have elapsed in eight or nine cases without any signs. Among other cures are cases of malignant tumor of the skin (proved by microscopic examination), of the mammary glands, and of those located in easily accessible cavities. He has had less result in curing sarcomata than carcinomata, though he has had 3 cases that have been absolutely cured. As long as a case is operable he would recommend removal of the growth, and when recurrence is noted, repeated application of the *x*-rays. Lupus vulgaris is amenable in 95 per cent. of cases, according to his experience.

55. **Proctocolitis.**—Beach sums up his points in regard to this disorder in the following:

> 1. Proctocolitis is a disease that attacks old and young. My experience and records show it to be more general in the male sex. 2. The essential symptoms are pain, constipation and membranes. 3. In diagnosis, appendicitis, malignant and pelvic diseases are to be eliminated. 4. Reflex symptoms must be recognized when they occur, as neuralgia, lithemia, vertigo, dyspepsia, cardiac irritation, asthma and neurasthenia. 5. The history of acute dysentery of bacillary origin and the neuroarthritic diathesis must be reckoned with as casual factors. 6. Ptosis of the abdominal viscera, appendicitis and tumors may be complications in severe cases. 7. The diet should consist, for the most part, of soft foods, eliminating green vegetables, fruits, fats and alcohol. Milk is the standard aliment. 8. Certain medicines are of use as indicated, but should be selected and used with great care. 9. With the above regimen the most efficient procedure is to wash out the colon.

59 The Differential Diagnosis Between Yellow Fever, Dengue Fever, Malarial Fever and Acute Yellow Atrophy of the Liver. F. Paschal.
60 Appendicitis—Some Remarks on Its Pathology, Diagnosis and Treatment. F. L. Barnes.

58. **Environment in Infectious Disease.**—M'Laughlin holds that the pathogenicity of micro-organisms is not a constant, invariable quantity, but differs directly with their capacity to manufacture disease-producing substances—toxins and toxalbumins. The capacity to manufacture toxins is affected by certain natural and artificial agencies. We call such a change in the micro-organism an attenuation. These agencies are unfavorable culture media, or are conditions of life in which the germs are compelled to exist. Sunlight is a powerful, natural attenuating agent, and he thinks we are justified in believing that there are other natural means of modifying the types of epidemics. Cleanliness in the home, in the municipality, pure air, drainage, temperature, humidity, etc., are often important factors.

61 *An Easy Method of Percentage Infant Feeding. C. W. M. Brown.
62 *Conclusions from Fifty-one Intubated Fatal Cases of Laryngeal Diphtheria. B. R. Shurly.
63 Effects and Treatment of Adenoids. H. M. DeJarnette

61. **Percentage Infant Feeding.**—Brown advises Townsend's method, published in the *Boston Medical and Surgical Journal* of March 25, 1899, as one of the simplest methods, that is, the decanting off of the upper one-fourth of milk from the total, which contains 10 per cent. of fat, with 4 per cent. proteids and 4 per cent. sugar. With 10 per cent. cream it is evident that one ounce of cream in a 20-ounce mixture would give a percentage of 1-20 of 10 per cent. or one-half of 1 per cent. of fat. In the same way the percentage of albuminoids would be 1/20 of 4 per cent., or .2 of 1 per cent., and the sugar would be .2 of 1 per cent. One more fact is needed before formulating the rule for human modification, that is, that an even tablespoonful of sugar of milk weighs 3.5 drams and each tablespoonful added to a 20-ounce mixture raises the percentage of sugar 2 per cent. It may be added that each tablespoonful of cane sugar, which may sometimes be used, raises it 3 per cent. The rule to be remembered is that each ounce of 10 per cent. cream in a 20-ounce mixture represents .5 of 1 per cent. of fat; .2 of albuminoids and .2 of sugar; and each even tablespoonful of sugar of milk represents 2 per cent. Thus if we order top milk 4 oz., water 15 oz., lime water 1 oz., sugar of milk, 2 tablespoonfuls, we are making a formula of fat 2 per cent., sugar 4.8 per cent., and albumin .8 per cent. If we order 8 ounces of top milk, 11 ounces of water, 1 of lime water and 2.5 tablespoonfuls of milk, we are making a formula of fat 4, sugar 6.60, and so on. He quotes Holt's summary of the most important indications for varying the percentages; if not gaining in weight and with no special signs of indigestion, increase the proportions of all ingredients; if habitual colic, diminish the proteids; for frequent vomiting soon after feeding, reduce the quantity; for regurgitation of sour masses of food reduce the fat and sometimes the sugar. For obstinate constipation increase both fats and proteids. Brown ends his article with the following conclusions:

> 1. The modification of cow's milk for infant feeding may safely be done at home under the care of the mother or nurse of ordinary intelligence, and is preferable to guess work. 2. It is based on the known composition of mother's milk, and also on the known dissimilarities between it and cow's milk, especially in the proteids. 3. The method of home modification and of calculating the percentages should and can be made extremely simple, and such modifications can be made sufficiently accurate and uniform. 4. The addition of cereals to the milk in the form of barley or oatmeal water is generally desirable after the seventh month, and is desirable before that age in some cases as an aid to the digestibility of the milk.

62. **Laryngeal Diphtheria.**—Shurly considers intubation the best practice in the hospital, though tracheotomy may be advisable outside, but he insists on the extreme importance of the early administration of large doses of antitoxin and the immunization of those exposed.

41 Ueber Darm-Tumoren in der Gegend der Regio iliaca sin. C. A. Ewald (Berlin).

23. **Salt Starvation Treatment of Epilepsy.**—Meyer's experience with 4 epileptics treated by deprival of salt and administration of bromin in the bread, was quite favorable on the whole. The seizures were less numerous and less severe during this dietetic treatment, but on its suspension they seemed to recur as previously. Bromin acne was observed in all the patients, showing that the action of the drug is intensified on this régime.

25. **Preventive Treatment of Primary Syphilitic Lesion.**—Hollaender states that cauterization without contact transforms the specific lesion into a pure granulating lesion which then heals. The difference in the reaction to this cauterization on the part of ulcus molle and of the specific ulcus serves to differentiate them. It is possible in certain cases to prevent secondary manifestations by applying this measure in time, as he has had occasion to establish in his experience with 80 cases thus treated. The cauterization without contact is with a jet of superheated air.

28. **Psychiatry and the Side-Chain Theory.**—Alter thinks that exogenous or autochthonous toxins are responsible for the seizures in epilepsy, paralysis and certain hysteric conditions, and that their action is explainable by the side-chain theory. Treatment should aim to divert these toxins into the excreta.

31. **Experiences with Sanosin.**—Behr found that sanosin had a favorable action on tuberculous subjects by increasing the appetite, but no other benefit from its use was apparent in his experience.

37. **Antistreptococcus Serum in Articular Rheumatism.**—Schmidt tried Menzer's serum in 15 cases. Six were unmistakably improved; 4 only subjectively improved and in 5 no effect was apparent. The more pronounced the reaction the better the results observed.

38. **Cryoscopy of Urine.**—Zangemeister advocates the practice of diluting the urine for functional test by the freezing-point. He shows that this ensures more accurate results and is valuable for comparison. The urine is diluted always to the same volume of fluid for equal periods of time.

42. **Neutrophile Leucocytes in Infectious Diseases.**—Arneth has a large work ready for the press on this subject. He proclaims that all our previous conceptions of the positive and negative chemotaxis for the neutrophile leucocytes has been based on false premises. Our assumption of the importance and meaning of hyperleucocytosis and hypoleucocytosis has been absurdly false. The explanation of the phenomena observed is the destruction of the neutrophile leucocytes which occurs in varying proportions according to the degree of infection or intoxication, the resisting powers of the organism and numerous other factors. In this preliminary communication he reports the most important findings of his research on the leucocytes. It has been conducted by a new technic, which commences where all other methods of investigation stop. It has revealed that the number of the leucocytes is no criterion as to their actual normal or abnormal condition. This depends on the condition of the nucleus. According to the characteristics of the nucleus the leucocytes may be divided into five classes. He has coined a new term to express these conditions, "cytosis," or "Zytose" in the Germaan, and distinguishes between isocytosis, anisocytosis, hypercytosis, hypocytosis and normocytosis. The condition in infectious diseases is always an aniso-hypercytosis (iso and aniso are the Greek terms for equal and unequal). Our present classification of leucocytes is shown by this new technic to be arbitrary and mistaken, while the new findings reveal much simpler and more regular relations between the various forms of white corpuscles. The new findings indicate that the neutrophile leucocytes are the producers of the antibodies, but not exclusively. Arneth does not describe his technic in this preliminary communication, but intimates that it is destined to throw light on many other of the finer physiologic and pathologic processes. He is assistant at von Leube's clinic at Würzburg, and his book is now in press at G. Fischer's, Jena.

43. **Radium Rays in Therapeutics.**—Scholtz mentions that the radio-active properties of radium are not affected by heating it to white heat or melting, nor by reducing its temperature to 252 C. below zero. He has been testing 25 mg. of radium bromid in the treatment of various skin affections and tumors and conducting experiments on animals. The treatment proved particularly effective in lupus and superficial cancer. The results indicate that the radium rays produce effects closely similar to those of the *x*-rays, in some respects resembling those of concentrated light. Even if they accomplish no more than the other methods of radiotherapy, the far greater convenience of their application ensures them a wide field of usefulness. The radium can be easily introduced into the mouth, nose, throat and vagina. It may prove possible to bury a particle of radium in deep-seated tumors. A particle might also be introduced into the maxillary or frontal sinus to produce an effect on tissues below, or into the joints. Such procedures must, of course, first be tried on animals, but the prospects are promising for their application to man.

44. **Remote Results of Operative Treatment of Jacksonian Epilepsy.**—Two cases of traumatic jacksonian epilepsy were reported in 1896 as cured by an operation five years before. They have figured since in statistics as successes. Engelhardt now states that one of the patients has been cured to date, twelve years since the intervention, but in the other case, after an interval of rare seizures for three years and nearly two years of complete freedom from them, they then recurred, and in less than two years the patient was driven to suicide by their severity and frequency.

55 *Treatment of Gastric Ulcer. M Wagner (Hamburg).—Zur Behandlung des Magengeschwurs

**47. Influence of Salt on Gastric Secretions.**—Bönniger's experiments were made on a dog with a Pawlow fistula. They demonstrated that salt has a marked inhibiting action on the secretion of gastric juice, confirmed by tests on a healthy human subject.

**50 Arm-Raising Test of Pressure in Right Auricle.**—Gaertner's new test was described in THE JOURNAL recently, page 68 Prym has been experimenting with it and states that it does not have the absolute significance which Gaertner attributes to it. Different veins collapse at different levels when the arm is passively raised, even on the same subject. The level is not determined alone by the pressure in the right auricle, but also by the elasticity of the veins, the resistance to the flow of blood and its greater or less viscosity, etc.

**55. Treatment of Gastric Ulcer.**—Wagner remarks that the aim of treatment of gastric ulcer in Lenhartz' service is always to abolish the hyperchlorhydria and likewise the anemia or chlorosis or other constitutional cause of debility, which is an almost invariable accompaniment of gastric ulcer and prevents its healing. For this reason the patients are put on a diet of concentrated albumin. This mode of treatment relieves the pains, and recovery is much more rapid and complete than with other methods of "ulcer cures" He gives the particulars of 60 cases thus treated, in all of which there had been more or less bleeding from the stomach The patient is required to stay still in bed for four weeks, using the bed pan, and the surroundings are made tranquil and cheerful An ice bag is applied to the stomach to prevent distension and to favor contraction while it relieves the pain The day of a hemorrhage the patient is given by teaspoonfuls iced milk up to 200 or 300 c c and one to three fresh, well beaten eggs, raw and cooled on ice Bismuth in suspension is also given, 2 gm. to the dose, kept up for ten days in severe cases The amount of milk is gradually increased by 200 gm at a time until by the ninth day the patient is taking 8 eggs and 1,000 c c of milk: 100 gm of rice cooked in milk is then allowed, with two rolls (Zwieback). The sixth day 35 gm of raw chopped beef is stirred in with the milk once and then twice a day afterward. Fifty gm of raw ham and 20 of butter are added to the diet the tenth day. The number of calories is thus 1,135 the sixth day, 2,168 the ninth, 2,478 the tenth, and 3,073 the fourteenth day, and when the four weeks are past, a mixed diet is allowed, the meat no longer taken raw All pains vanished on this diet by the third day in 12 cases, by the fifth in 6, by the eighth in 5, by the fourteenth in 1; one patient had a continuous pain on pressure, and 35 had no pains at all after this diet had been instituted Its chief advantages are that the pains are abolished and that the patient leaves the hospital cured not only of his ulcer but of the underlying anemia or debility of any kind Out of 25 followed to date, 18 have been in good health since; one patient has had occasional pains, but not enough to interfere with her working capacity, and 3 have had each a single transient period of pains for one to four weeks One patient absolutely refused to follow the restrictions of the course and was dismissed uncured, rejecting the advice to have the readily palpated chronic ulcer ablated. Only 2 have had any bleeding from the ulcer since, and one of these patients left before the course of treatment was complete The other has once in a long while vomited small clots, but has been otherwise in good health

**62. Causal Agents of Cancer.**—Feinberg defends himself against the usual criticisms of announcements in this line by stating that the histosporidium carcinomatosum which he has discovered is the result of years of cautious unremitting toil, and he publishes the description of it after mature deliberation. He first argues to prove that all the facts observed in cancer speak in favor of some animal parasite as the direct cause of the growth. The latter is in reality merely the results of the process of local resistance *by the epithelium cells against the invasion of the parasite.* His histosporidium appears as a nucleus surrounded by a clear zone and this in turn by protoplasm and an enclosing membrane. It has a dual life cycle, passing through one phase in the tissues and another outside, the latter requiring considerable time. This explains why direct inoculation of substance from a cancer does not produce the growth in other subjects. The second phase of the cycle must be passed through before the parasite is ready to renew its invasion of the tissues. *No surgeon has ever been inoculated with cancer from casual contact with one, but long continued contact with a cancer subject* allows the cancer parasite to develop through its second phase and it is then ready for another invasion. The article is illustrated.

**63. Juvenile Tabes.**—Marburg reports a case of tabes in a boy of 10 *who had acquired syphilis in infancy from a nurse He also tabulates 31 other cases under the age of 21 which he has found in the literature.* He remarks that all the symptoms observed in tabes in an adult are encountered likewise in infantile and juvenile tabes, the only difference being in their relative frequency or rarity. Syphilis was positive in all but 4, and in these was probable. It was acquired in 2, but in all the others had been inherited. The coincidence or succession of several infectious diseases, scarlet fever, diphtheria and measles after pertussis, or an injury to the head, seem to favor the development of tabes in children with a hereditary burden. In some of the cases an inherited predisposition to nervous affection was noticed; in others the onset of puberty apparently favored the outbreak of the tabes Lancinating pains were noted in 21, girdle sensations in only 4, and initial headaches in 5 out of the total 35. Sensory anomalies were noticed in two-thirds of the patients, and Romberg's sign in three fourths, as also bladder disturbances In 12 there was total atrophy of the optic nerve or beginning blanching of the papillæ. In only a single instance were there no objective optic findings. In his experience, the development of the optic atrophy coincided with an arrest or improvement of the tabes. In his own ophthalmic service during the last nine months he has met with 55 cases of genuine optic atrophy, including 22 tabetics. Only 12 of these presented evidences of antecedent syphilis, and the interval since infection ranged from six to forty years, sixteen years in 3 cases. Only 7 of these 22 tabetic subjects presented the Romberg sign and there was no ataxia in any. In some, the tabes had been always mild since its inception twenty to twenty-five years before, confirming the experience of others in regard to the mildness of the cases in which optic atrophy is a prominent symptom at any time in their course.

**64. Symptomatology of Diabetes.**—In Mager's patient the pulse, from 44 per minute in a reclining posture, increased to 66 when he sat up, dropping back to 44 when he reclined The beat and curve resembled those observed during convalescence from typhoid. The necropsy confirmed the assumption of degeneration of the heart, probably from the acidosis of the organ and loss of normal alkalinity.

**65. Extirpation of High Cancer of Rectum.**—Sato mentions that he has operated on 20 cases of rectal cancer by the perineal or sacral route during the last two and a half years in his private hospital at Tokio. He describes another case in which he preferred the abdominal route. He made his incision between the umbilicus and symphysis, retaining the anal portion of the rectum, closing the upper end, after resection, making an artificial anus in the center of the abdomen. He fastened the colon in a gentle curve to the artificial anus, which allowed the feces to accumulate in it as in a pocket and thus ensured continence. The extirpated tumor proved to be an adenocarcinoma with glandular metastases, but the patient has been cured and in good health to date, more than sixteen months. By this method the anal portion of the rectum can be examined frequently and recurrences detected early. The more inaccessible the rectal cancer the more imperative the indications for this technic.

66. **Tolerance of Carbohydrates in Diabetes.**—Kolisch, in continuing his research on the dietetics of diabetics, has found that albumin is responsible for the glycosuria in severe diabetes, not the carbohydrates. He gives the tabulated findings in 4 severe cases in which after establishing by dietetic means a constant balance between the intake and output of carbohydrates and nitrogen, he then suppressed all albumin and substituted it by carbohydrates. The "standard ration" represented 2,500 calories a day, and included 250 gm. green vegetables; 200 gm. butter; 200 gm. sausage consisting of 34.1 albumin; 300 gm. lean beef; 150 gm. aleuronat bread (representing 20.57 per cent. carbohydrates), a pint of coffee, of bouillon and of wine. When the balance was established on this standard diet the albumin and meat were substituted by equal or larger amounts of potato, 300 to 1,000 gm. The supposed limits of toleration for carbohydrates was exceeded even on the "standard ration," and yet further addition of carbohydrates caused only a trifling increase in the amount of sugar or a marked reduction, when the ingestion of albumin was restricted. Even after return to the "standard diet" the proportion of sugar remained low. The albumin, not the carbohydrates, is therefore responsible for the glycosuria; the carbohydrates have only a subordinate share in its production. He thinks that these facts corroborate his assumption that diabetes is primarily due to an abnormal cleavage of the carbohydrates, induced by some toxic factor. Also that the toxic factor is due in some way to the ingested albumin. He emphasizes the necessity for keeping the number of calories down to as low a figure as compatible with normal functioning, and remarks that the benefits derived from oatmeal, potato and milk cures in the treatment of diabetes are readily explained by the results of his tests.

70. ***Medication in Tuberculosis.***—Gemelli quotes Maragliano to the effect that the best way to test a drug is to administer it for a certain length of time to an animal and then test the properties of its serum—obtained by venesection—in respect to given bacteria. This will afford us better insight in regard to the action of the drug on the bacteria than any other method. Tests in this way of turpentine, iodin, creosote and sodium cacodylate have recently been made at his clinic. The results showed that the action of the drugs separately was almost completely negative. Gemelli has tested some of these same drugs given simultaneously, believing that the interrelations between them might affect the results observed. He also describes a case of long-standing tuberculosis in the first stage which seemed to offer prospects of a cure by medication. Sodium cacodylate was administered by the mouth and an iodo-iodid solution with guaiacol injected. The condition seemed to be improving at first, but then took a turn for the worse, and the patient succumbed to repeated hemoptyses. He is convinced that this aggravation of the disease was due to the medication, and affirms in conclusion that the experiments at the Maragliano clinic are completed by his experiences, and that they demonstrate that certain drugs, such as iodin, not only have no favorable action in tuberculosis, but are distinctly injurious. Also that arsenic, as in the sodium cacodylate, on account of its known vasodilating properties, favors hemoptysis, and it is actually criminal, in his opinion, to prescribe it in tuberculosis.

74. **Behavior of Certain Viscera After Cutting off their Circulation.**—De Renzi and Boeri have been conducting extensive research which has convinced them that the omentum can almost be said to have an intelligence of its own, it assumes such a protecting rôle when certain of the viscera are injured. (See THE JOURNAL, xli, p. 888.) It has both a plastic and a mechanical, and also an antitoxic and an antibacterial action. They now announce that when the circulation of the spleen or of a kidney is entirely cut off by ligature of all its vessels, the omentum approaches it and soon envelopes it completely. A capsule of fibrous tissue is thrown around the organ and it shrivels away and is completely absorbed in a comparatively short time. The same thing is observed in regard to a foreign body. The omentum gradually envelopes it, forming an investing capsule inside which it is either completely absorbed or remains as a harmless body. When the circulation in the spleen is only partly arrested the omentum invests it and supplements the deficient circulation by means of its own vessels. If the omentum is resected before the vessels in the spleen are ligated, the animal succumbs. The spleen, after its circulation is cut off, decays like any foreign body, and the omentum seems to have the power to neutralize the poisons generated in this process of decay. The animals showed very little disturbance after resection of the omentum if the spleen was removed, while leaving it in place and arresting its circulation proved invariably fatal. Among the numerous interesting facts noted in this research is the appearance of albuminuria and casts in the urine after the circulation of one kidney has thus been cut off. Its mate is evidently overwhelmed at first by the extra task thrust on it by this sudden suppression of the other kidney. This is not observed after nephrectomy, or at least not to the same extent, as this operation is not undertaken except when the kidney has been more or less impaired for a time, thus gradually accustoming its mate to the extra task of compensation. Hemoglobinuria is also observed after cutting off the circulation of the kidney, which he explains by assuming that the decay of the kidney generates toxins which have a hemolytic action. In nephrectomized dogs the removal of the remaining kidney did not prove fatal for sixty-eight hours on an average, while ligating its vessels entailed death in forty-eight hours. This confirms Maragliano's assumption that in uremia the symptoms observed are due more to the cellular toxins arising from the decomposition of the diseased organ than from retention of the elements of the urine.

75. **Digitalis and Venesection in *Pneumonia*.**—Zuccala has treated 14 patients with lobar pneumonia by large doses of digitalis—as much as 4-5 gm. a day in 200 gm. of infusion,

supplemented in 5 cases by venesection. The results corroborate the assertion that digitalis has marked bactericidal action against the pneumococcus. This action may be called actually specific, as it is able to save guinea-pigs against fatal doses of the pneumonic toxi-albumins, or at least long postpones the fatal termination. Clinicians need have no fear of cumulative action. Venesection is a valuable adjuvant when the toxins of the disease process are unfavorably affecting the heart ganglia, when the symptoms indicate toxemia, and there is dyspnea, when the heart has an extra task imposed on it by the extent of the process in the lungs and the stasis in the minor circulation. Withdrawal of a certain amount of blood relieves the heart and checks the progress of the pneumonic process. If dry cups and leeches do not prove sufficient, venesection may accomplish marvels, as in some of the cases he describes in detail. He drew about 800 gm. blood.

79. **Detection of Strychnin in Putrefied Blood.**—Astolfoni is enthusiastic in regard to the delicacy and reliability of Vitali's method of detecting the presence of strychnin in putrefied blood. The strychnin is easily isolated from the organic alkaloids and this isolation is not interfered with even by advanced putrefaction. The blood is first acidified with tartaric acid and heated in a water bath to coagulate the proteid substances. It is then divided into two equal parts, each of which is digested for six hours at 70 C. with twice its weight of absolute alcohol. It is then cooled, filtered and the alcohol evaporated. The aqueous residue is cooled, filtered and evaporated on the water bath, and the residue dissolved in absolute alcohol. This last alcoholic solution is again filtered and evaporated to a syrup. It is then rendered alkaline with barium hydroxid and then shaken up with four times the amount of ether. The ether is then distilled and evaporated out to dryness. The residue is yellow, bitter and alkaline. It is neutralized with a few drops of a dilute solution of acetic acid. The filtered fluid is again rendered alkaline with barium hydroxid and again evaporated with ether. This ethereal solution is then slowly evaporated on the water bath with very little heat, and the crystalline residuum is the strychnin. Vitali established by tests on animals, etc., that the strychnin thus derived is almost absolutely pure while the loss is negligible. These assertions were fully confirmed by Astolfoni's six tests of blood to which a known amount of strychnin had been added. Vitali's technic was first published in the *Bolletino chimico e farmaceutico*, 1896, No. 16.

83. **Direct Action of Formalin on the Kidneys.**—Putti injected a 1 to 4 per cent. solution of formalin directly into the kidneys of a number of rabbits. It always induced necrosis and deposits of calcium salts accompanied by trivial fatty degeneration. The connective tissue proliferates abundantly to take the place of the destroyed parenchyma of the kidney. A small percentage of albumin was always found in the urine of the animals thus treated, but neither the aldehyd nor the formic acid reaction could be obtained from the urine.

89. **Elimination of Formaldehyd.**—Considerable research has been undertaken in Italy to determine whether formaldehyd passes unmodified through the system. Tests of the urine, exhaled air and of the tissues of animals after administration of formaldehyd have absolutely failed to reveal its presence as such. [illegible]

90. **Paratyphoid in Children.**—One of the two children was 2, the other 7, and both presented the typical symptoms of typhoid fever, including enlargement of the spleen. In one there was no hyperleucocytosis and the pulse was dicrotic. In the other there were roseola patches, and other members of the family were similarly affected. The fever persisted thirty-two and twelve days, terminating with a crisis in the first case. The agglutination test with typhoid bacilli was negative, but faintly positive with colon bacilli, but the cultures derived demonstrated that the infection was due to a paratyphoid bacillus. Allaria is convinced that the typhoid bacillus, the colon bacillus and the paratyphoid bacillus are each able to produce a specific disease, the symptom-complex of which may be identical for each, but which are in reality three different diseases, etiologically considered, and they can be absolutely differentiated by the agglutination test.

93. **Total Subcutaneous Emphysema.**—Tozzi knows of no other case in the literature similar to the one he describes. A healthy little girl, 9 years old, was suddenly seized with spasms of suffocation, the laryngeal spasms and cough suggesting diphtheria, but there was no abnormal temperature. The possibility of worms in the air passage was considered and santonin given. Ascarides were voided, but the child still had suffocating spasms, with great prostration, and coughed up somewhat hard sputa, auscultation revealing râles, but nothing else being abnormal elsewhere. The symptoms were somewhat mitigated the next day, but then the neck swelled, evidently due to the presence of air in the subderma. The emphysema enlarged until finally the chest and arms were swollen in the same way to an incredible size. The eyelids became so swollen that the eyes were completely closed and the entire body was thus puffed up with an almost total subcutaneous emphysema. The parents refused to allow puncture or any intervention, expecting the child's death any moment. She remained in this condition for six days, after which the symptoms gradually subsided and in less than a month she was restored to her usual health with no traces of her peculiar experience. He thinks that the emphysema was probably due to some laceration of lung tissue in the primary laryngeal spasms and violent coughing.

100. **Antitoxic Action of Iodin in Regard to Tuberculin.**—Spadoni found that guinea-pigs did not lose in weight when tuberculin and iodin were injected together or consecutively. Either alone caused marked emaciation. He therefore assumes that the iodin has an antitoxic power in respect to the tuberculin.

103. **Carcinoma.**—Monsarrat, in 1899, described an organism isolated from carcinoma. His researches have been continued, but were confined to carcinomata of the female breast. The organism is described at length. It was isolated from 58.3 per cent. of mammary carcinomata and was traced through two cycles of the life history, first the vegetative budding cycle, the other the sporulating cycle. When injected into animals

it is capable of infecting and inhabiting endothelial and epithelial cells. The organism initiates in endothelium and epithelium a process of proliferation as a result of which masses of new-formed tissue are built up, consisting of parenchyma and stroma, growing and extending actively from their centers of origin. The new cell-mass formation may be associated with growths in the neighboring glands and some evidence of visceral metastases was also obtained. Intracellular bodies are demonstrable in carcinomata of the breast presenting the same features as intracellular parasites of experimentally-produced nodules. He thinks the conclusion justified that the organism described is a causal factor in mammary carcinoma.

104. **Carcinoma of the Colon.**—Pollard concludes from its comparatively inactive course that carcinoma of the colon, if taken sufficiently early, can be successfully operated on with the expectancy of at least a long period of quiescence. The difficulty is to make the diagnosis early enough, it is so insidious in its beginning. In any case of chronic illness, however slight, associated with dyspeptic symptoms, a thorough abdominal examination should be made and a tumor of the stomach, intestines or other organs may be detected when least looked for. The symptoms are those of impediment to the intestinal contents. Indigestion or flatulence is of most common occurrence. When there are attacks of pain, colic, some loss of flesh, evidence of malignant growth of the bowel, and hemorrhage, a careful physical examination should be made and an abdominal tumor would probably be detected. Displaced kidney can always be returned by local pressure to its normal position, and he is inclined to rely absolutely on this sign. Carcinoma about the hepatic flexure might suggest an enlarged gall bladder and may invade the stomach and produce similar symptomatic symptoms. If there is an obstruction to the bowel it will rarely be possible to feel the growth, and the best procedure, he thinks, would be to explore the abdomen through a median incision below the umbilicus. If there is no material obstruction and the tumor can be felt, an incision should be made, as a rule, over the tumor, and long enough to allow the necessary manipulations. He insists on special care as to asepsis, as the open bowel is a constant source of infection. Pollard favors anastomosis by stitching rather than by the use of the common mechanical appliances. Seven cases are reported; all made good recoveries, though in some phlebitis of the superficial veins of the leg complicated the convalescence. It is remarkable how often this complication occurred. He has noticed it also in appendectomy, and thinks it may be due to some slight septic contamination of the blood.

105. **Radium Bromid.**—Davidson has employed radium bromid in rodent ulcer, tuberculosis of the skin and rodent cancer of the nose with decided improvement and arrest of the disease. He says it is fairly clear that radium produces profound changes in rodent cancer and that the absorption of the altered products leads to the blush that so often followed. If the exposure has been too long the blush may be succeeded by severe inflammation, resembling erysipelas, as in a case reported. He thinks it is possible that the products absorbed act as antitoxins, but there is no evidence of this. With large surfaces, care must be taken to avoid overexposing the parts to radium and to avoid constitutional disturbances. He thinks radium may prove to be a very valuable therapeutic agent, but it remains to be found in what diseases it is potent and what may be the best method of using it. In sealed glass tubes it may be applied readily to any part, be introduced into cavities, etc.; is painless in application; it does not even prevent the patient from reading, etc., when the treatment is going on. In several cases of carcinoma no specially good results occurred. He concludes by remarking that thorium, though about 1,000,000 times weaker than radium, has similar effects and can be obtained at moderate price and in large quantities. It can be used in a rubber bag and applied to the part. He thinks it would be well to try thorium in cases where radium is also being applied.

107. **The Leishman-Donovan Body.**—Manson and Low have investigated the life history of the Leishman-Donovan parasite, and think that they find in it a possibility to be reckoned with in tropical pathology. Its life history ought to be well followed out to determine how it obtains entrance into the human body. They think it is safe to assume that once in the spleen it multiplies by simple division and it gets out of the body, in all probability, through the blood current. A case of splenomegaly in which this parasite was found occurred in a European tea planter from Assam, and is reported.

108. **Human Trypanosomiasis on the Congo.**—Examinations were made by Dutton, Todd and Christy, of the parasite in the Congo region. They conclude with the following summary:

> The examination of trypanosomes seen in stained specimens of blood from cases of trypanosomiasis, from cases of sleeping sickness (typical or doubtful), in the specimens of cerebrospinal fluid of the latter cases, and in the blood of experimental animals, infected with either of the three above-mentioned fluids, has led us to the following conclusions: 1. The trypanosomes seen in the blood of man, whether symptoms of sleeping sickness were present or not, have always been the same. The number of cases in which trypanosomes from the spinal fluid have been examined is at present too small to permit of a definite description of morphologic characteristics. We have seen forms in the cerebrospinal fluid similar to those described by Bruce and Castellani, and also longer forms similar to those seen in the finger blood of the same cases. 2. None of the human trypanosomes seen, whatever their source, have presented any morphologic appearance incompatible with *Trypanosoma gambiense*. 3. The parasites seen in rats inoculated with the cerebrospinal fluid of cases admitted to the hospital for sleeping sickness are the same as those seen in rats inoculated with the blood of cases of either sleeping sickness or simple trypanosomiasis. 4. The organisms seen in the blood of rats inoculated with trypanosomes from any of the three indicated sources have up to the present shown no differences from those observed in animals infected with *Trypanosoma gambiense*. We have observed the extraordinarily long forms with prolonged flagella and the stumpy forms with short flagella, described as occurring in animals inoculated with the Gambian parasite. We have therefore no reason to suppose that the organisms seen by use in the Congo are other than *Trypanosoma gambiense*.

111. **Blood Examination.**—Wright describes a method of drawing off the blood into a calibrated capsule in a citrate of soda solution and how the filling in of the measured charge of citrate of soda solution can be accomplished, thus avoiding the embarrassments due to clotting of the blood, etc. He describes in detail the methods of manufacture of the automatic pipettes which are used, the procedure of drawing and examining the blood in dilution and otherwise. He says the method has no pretense to absolute accuracy, but, he thinks, that making a series of such tests yields very concordant results, considering the necessary limitations.

### THE EARLY SIGNS OF PREGNANCY.

A CONTRIBUTION TO ITS CLINICAL STUDY, WITH ONE PATHOLOGIC SPECIMEN.*

H. L. E. JOHNSON, M.D.
Professor of Gynecology and Clinical Gynecology in the Medical Department of the Columbian University.
WASHINGTON, D. C.

We are familiar with the usual physical signs of pregnancy in women and their relative importance, when considered singly or collectively, in influencing our diagnosis of the existence or non-existence of this condition. Some are early manifestations, while others are late in the cycle of uterogestation. These several physical signs are, according to their diagnostic value, usually classified as presumptive signs and positive signs, and, when existing, remove all doubt in a particular case, though the consideration of all necessarily delays for some months a positive diagnosis.

These signs or symptoms, though usually clear and distinct, are often obscured or modified by concomitant pathologic conditions, such as, for example, tumors, malignant or benign, within the generative area, ectopic gestation, etc., making a late diagnosis difficult or doubtful, and an early one, in some instances, practically impossible.

I shall confine this paper to the consideration of the diagnosis of pregnancy prior to and including the third calendar month, and indicate and describe a particular physical sign, which, in a very large number of cases both in private and hospital practice, I have invariably noted and which has been observed only in cases where the diagnosis of pregnancy has been subsequently positively demonstrated. This sign is observed as early as the fourth week, or possibly earlier, and consists of an intermittent softening and hardening of the vaginal portion of the cervix uteri with, in many cases, a change of color, from a pale violet to the normal pink hue, or the reverse. These changes in consistence and color are rhythmic, more or less. The alternate softening and hardening is easily detected by digital touch, while changes in color may be seen through a speculum.

These signs or processes are, in all probability, early manifestations of what is subsequently recognized as the intermittent contractions of the pregnant uterus, and are probably due to a necessity for some change or modification in the uterine circulation incident to the nourishment and growth of the impregnated ovum through physiologic intermittent congestion of the generative system.

I have never observed this sign or symptom in any other normal or diseased condition, and after careful investigation of a large number of cases, I consider it an invariable early sign of recent impregnation.

While I could cite a large number of interesting corroborative cases bearing on the subject, I will only give brief notes on a few selected ones which present different features in diagnosis.

CASE 1.—Miss —, aged 23 years, white, menses painful, scanty, irregular, leucorrhea, "thinks she has womb disease," missed last period. Examination: Left tube enlarged and tender, uterus anteflexed, size about normal, pinhole os. Sign present. Several observations made. Diagnosis, pregnancy. Patient doubted diagnosis; subsequently admitted secret marriage three and a half years before, and made public announcement, confined 230 days after my first examination.

CASE 2.—Miss —, aged 16½ years, white, specific vaginitis (confirmed by stain test), never menstruated, no morning sickness. Examination: Sign present. Diagnosis, pregnant two months. Patient asserts this to be impossible, never exposed. Was under observation at times until the seventh and a half month. Motion and fetal heart sounds noted. Patient left city for sanitarium. Subsequent history unknown.

CASE 3.—Mrs. —, aged 38 years, white, five children, menses always normal and regular, complains of constant nausea and vomiting. Examination: Bilateral laceration of cervix uteri. Uterus enlarged. Sign present. Diagnosis, pregnant about three months. Patient would not believe that she was pregnant, though she wanted another child. Menstruated regularly four succeeding months. Confined on time; labor normal, no hemorrhage.

CASE 4.—Mrs. —, aged 30 years, white, married 9 years, 4 children, youngest 3 years old; menses never regular; does not remember date of last period, often misses from one to five months; is sure she is not pregnant. Consumption in family. Asserts she has "lost one lung from hemorrhages." Abdomen very large, thinks she has a tumor, as "they run in the family." Examination: Abdomen distended with gases; perineum and cervix lacerated. Sign present. Diagnosis, two months pregnant. Patient protested and would not believe pregnancy possible, fainted and became hysterical; dismissed me and consulted another physician, who delivered her on time.

CASE 5.—Mrs. —, aged 40½ years, white, six children, three miscarriages; menses usually every three weeks, painful, profuse with clots and shreds, lasting from five to eight days, thinks she has "change of life working on her." Expected period fifteen days late. Examination: Perineum lacerated, uterus enlarged, prolapsed; cervix lacerated; left ovary enlarged, size of a hen's egg, prolapsed and fixed. Sign present. Diagnosis, pregnant between two and three months. Patient glad she did not have cancer, doubted being pregnant, flew into a passion, abusing her husband. Returned in six months, diagnosis confirmed. Lost track of case.

CASE 6.—Miss —, aged 21 years, white, shop girl, health perfect, menses always normal and regular until after two exposures three months before consulting me. Very nervous, hysterical; has had several convulsions and fainting spells. No logic field, such as vision, hearing, memory or the sexual sphere. Each of them merely signifies to me that associated with a universal loss of cellular force throughout the brain there is a more pronounced exhaustion in some cerebral area. In this area the brain cells have lost their power to rest more markedly than in other cerebral areas and, therefore, symptoms of fatigue are especially shown in the anatomic or physiologic district of the body governed by the more affected brain area. If, for instance, the cells of the frontal lobes are most impaired in their recuperative power, symptoms from the higher intellectual centers will supervene; there will be more impairment in the faculties of memory, judgment, ideas, than in the purely physical functions. If there be a more advanced stage of cellular exhaustion in the occipital lobes, vision is apt to be most involved. If the motor areas of the brain are most concerned in the cellular process, then muscular manifestations—tremors, jerkings, weakness, even to paresis and paralysis of the arms and legs—are apt to dominate the symptomatic field. However, in all of these conditions we find the associated general low state of vitality.

---

* Read before the Washington Obstetrical and Gynecological Society, Dec. 4, 1903.

This is not true where we encounter those peculiar "local neurasthenic states" *unaccompanied by any signs* of a general loss of tone or lack of vitality. In these instances, by contrast, the evidence of local fag seems the more pronounced. To me the so-called "occupation neuroses" appeal strongly as being of the above type, namely, purely "local neurasthenic states." Of these, the commonest are "writer's cramp," "telegrapher's arm," etc. They are all of them dependent on local *cellular brain exhaustion*. I do not consider them in the least as peripheral nerve affections. If they were of the latter sort, they would probably be easily cured. It is because they are due to the loss of power to rest through overtaxation of the brain cells governing the affected part that these peculiar maladies are so difficult to overcome. Now the question may most aptly be asked, "Wherein lie the causes of this loss of power on the part of the brain cells, and what is the essential nature of this force which is inherent in these brain cells?" That this problem is a most difficult one to solve, everyone will be, doubtless, willing to admit, and I confess it requires no small degree of assurance on my part to attempt its solution or explanation. Nevertheless, I shall place before you my ideas on this subject. If I felt they were mere idle fancies on a most fascinating question, I should not bring them to your consideration, nor lay myself open to the censure of frivolity on a matter of so serious import.

For a number of years, through study and observation, I have endeavored to explain to myself the phenomena exhibited by patients suffering from loss of vital force. The many nervous affections coming under my daily observation have given me ample opportunity to study these phenomena. In conditions of neurasthenia especially, this occasion is most strikingly afforded, for we find so many associated processes, like anemia, deficient oxidation, and, secondarily, tuberculosis of the lungs, in conjunction with it, that we possess definite criteria by which to measure our deductions and our efforts in treatment. As to the causative factors in bringing about this loss or waste within the brain cells, they are doubtless varied and many, but each of them alone or combined seems to me to effect ultimately one condition so far as the nerve cell itself is concerned. The cell is kept in a state of circulatory overnutrition or overexcitation, whereby its contactile elements remain in activity and the cell is prevented from resting and recuperating its force. Just what this force is no one has ever fully explained, nor do I claim, beyond these suggestions, to have arrived at an absolute conception of this force which, for want of a better name, has been termed "vitality." From the above, it will be inferred that I place the brain cell on a plane similar to that of a storage battery. This is to a great extent true, allowing for the difference between a living and an inert cell. As a matter of fact, I do consider essential nerve cells as closely allied to those making up a storage battery; and, furthermore, I believe the force emanating from each is similar in nature. We know that the force emitted by the storage battery is electricity. We can not definitely say that that of the nerve cells is identical with, but there is ample reason to believe that it is similar to, electricity. Granting, for the moment, that the vital force of living protoplasmic matter is similar to, if not identical with, electricity—and there is no valid ground on which to oppose such a conception, inasmuch as no one has ever shown just what the force we call "electricity" is—then we must ask ourselves, "whence comes this force?" How are the brain cells *replenished when once they have used up their quantum* of stored-up energy? Have we elsewhere in the human system *any evidence of a power to generate electrical or electro-magnetic force?* If so, how is it carried particularly *to the cells of the brain?* We know, *with a fair* degree of positiveness, that there is no organ within the body *which can be assumed to act as a systemic dynamo*, but, on the other hand, we know with equal positiveness *that there are evidences of polarity of two kinds* within the system. There is a chemical polarity, whereby an acid medium lies in juxtaposition to an alkaline medium, as shown along the digestive tract and elsewhere, and, then, to this theory more intimate, a cellular polarity in the tissue of the blood—a living, moving tissue which reaches and nourishes every part of the organism, the brain cells included.

Two qualities are essential to a conception of polarity, namely, attraction and repulsion. We may call these technically positive and negative affinities or poles, parallel with the terms used in electro- and magneto-physics.

The red blood corpuscles show to a high degree this polarity. In health this polarity is essentially in play, for on any other supposition the peculiar attraction of the red blood corpuscles for each other could hardly be explained. It is this inherent quality which causes the "gold roll formation" characteristic of normal blood tissue. Any impairment or loss of polarity, as seen in low conditions of vitality, as in advanced neurasthenia and tuberculosis, is followed by the breaking up of this normal gold roll formation characteristic of the healthy state.

I am aware that the above idea may seem at variance with the most recent results of the *investigations* of Flexner, his pupils and others engaged in research along the lines of certain *bacterial-endo-toxins*, and their discoveries of hemolysins, leucolysins, hemagglutinins, precipitins, *coagulins, etc., in human blood* under certain conditions. Yet I do not see why any variance should really exist, or why we need believe that the existence of these toxic substances in any wise invalidates *the conception of the polarity* of the red blood corpuscles.

In addition to this quality of polarity, which I regard as *electromagnetic*, we know positively that the red blood corpuscles are the active chemical carriers of the system; that to them is due the oxidation so essential to tissue metabolism. If these red blood corpuscles are capable of carrying necessary chemical elements and bearing active oxygen to the various tissues, there seems to me no adequate reason to discountenance the idea that they may also carry other forces, possibly of an electric or magnetic or electromagnetic nature, especially as we know that these can be produced through chemical agencies. To the red blood corpuscles we must ascribe, on this theory, the fundamental generative power, or at least this power in conjunction with extrinsic influences like sun light or the energy of food stuffs, which in turn have derived their energy from the sun light. To the nerve cells we must ascribe the conserving and releasing power of this force conveyed to them either in generated form or in a form which they themselves are able to convert into energy of an electric character.

The red blood corpuscle is the fundamental unit or ion on which this theory depends, and it is on this basis, namely, the power of the red blood corpuscle to assimilate certain rays of light or to take from them certain chemical or electrochemical elements, that a method of treatment has been elaborated, the main features of which I wish to detail to you. It will, I think, appeal as a logical method, evolved out of the foregoing line of thought.

We know that the sun radiates three qualities of rays. The calorific or heat rays, for the most part lying beyond the red; the luminous or light-giving rays, such as lie between the red and the violet of the spectrum; and the chemical or actinic rays, invisible to the eye under ordinary conditions, lacking in heat but most potent in their chemical, notably, their oxidizing property. The actinic rays lie mainly beyond the violet of the spectrum, in what has come to be called the ultra-violet zone, but the violet zone also possesses marked actinic qualities. Of the rays perceptible to the eye as seen in the prismatic spectrum, the red are the hottest, the orange next hottest, and so on, till we reach the violet which, while they are the coldest, still emit the greatest light on account of their shorter wave length. All of the luminous rays, that is, those we can see, differ in wave length only. It is this difference in wave length that induces the difference in color. When wave lengths become either too long—as in the infra-red zone—or too short—as in the ultra-violet zone—they become invisible to the human eye, though not to human consciousness and human utilization.

When rays of light, whether from the sun or any other luminous substance, strike an object they do one of three things, alone or in conjunction, namely: 1, They are reflected or turned aside; 2, transmitted or passed on; and 3, absorbed or utilized by the object itself. Probably every object does all three to a certain extent, but we have here to deal only with the last-mentioned factor, the *absorption* of light. Objects differ widely in their coefficient of light absorption, but probably every object absorbs light rays to a greater or less degree. Notably is this true of the violet and ultra-violet rays, whose characteristic is chiefly chemical or actinic. It is this actinic force that we are henceforth to consider and mainly in its relation to tissues. In other words, its action in maintaining health, in the prevention of diseases and in their treatment.

I believe I have elaborated a method of great practical value, thoroughly scientific in its principles and eminently qualified to produce excellent therapeutic results, directly corresponding to those which are naturally taking place around us through the action of sunlight, and in every respect verifying on living beings suffering from various diseases, the experiments demonstrated in our bacteriologic and hygienic laboratories.

To begin with the simplest method, the action of pure sunlight. We know, and have for ages known, that where the beams of the sun are shed disease is practically never encountered. From remotest periods to the present day it has been recorded that the most salubrious locations were those flooded with sunshine, and equally as a matter of record that where sunshine never falls we are certain to find disease. Sunshine purifies everything it touches, disinfects every object it penetrates, and retards or destroys every known form of germ life, even when these germs are of the most virulent type and in the most favorable culture media.

The more the sun's rays are absorbed and the longer the exposure to the action of the rays the greater will be, and is, the effect attained; but it must not be supposed that this effect is due to the heat of the solar beams. While it is always inseparable from this quality, it is almost purely the actinic action to which is ascribable this beneficial influence. That this is true can be definitely and readily demonstrated by anyone with a large prism exposed to the sun, and with an ordinary culture tube containing almost any germ in virulent stage. It will be found that all forms of light rays have a beneficial action, but that this becomes markedly greater as we proceed in the exposure successively from the red—the hottest—to the violet—the coldest—zones of the spectrum. It is, therefore, not a thermic, but a chemical, an actinic action we encounter. It follows, then, as a matter of course, that the nearer the surface the diseased tissue lies the more readily the actinic force will become applied.

The simplest form of application is the direct sunbath, where the nude body is exposed to the sunlight. Simple as this method is, it is woefully neglected. Moreover, it is effective in almost all conditions of debility, notably after wasting diseases like typhoid. The younger the individual and the more absorptive the skin, the better the result will be. The sun-rays become directly absorbed by the tissues, the blood corpuscles coursing in the vessels beneath the epidermis, and deeper, are bathed in sunlight. The chemical action of the light unfolds itself to the extent of increasing the oxygen-carrying property of the hemaglobin, and even to the augmentation of the corpuscles themselves, both red and white. Herein we have a distinctly actinic force, the primeval actinic method available to any person, free, God-given wherever the sun may shine. Just here, however, lies the difficulty.

The sun is so frequently obscured by clouds or mists that his effect is lost to a vast degree, and we are forced to seek either a locality where atmospheric conditions are favorable or create an artificially favorable atmosphere; one where there is ample light, akin to sunshine, and best, associated with the purest of air containing large quantities of ozone, free or nascent. These two, light and ozone, are absolutely inimical to disease, to germ life in any form. They are found, as is well known, mainly at an altitude far above the sea-leved; on mountain top. Unfortunately, every invalid can not seek such localities, and besides, the factor of altitude plays an unfortunate rôle. It changes the breathing basis. If this change in the breathing basis is maintained long enough, individuals living thus must continue to dwell under similar conditions. If they pass to low altitudes, a quick relapse is apt to occur. For this reason I have been led to seek to create an atmosphere similar to that of the mountain top, rich in light and ozone, but without altitude. I have believed that this could be attained, and have steadfastly worked toward that end, assured that if successful, it would accomplish both extreme oxidation and germicidal effect, thereby covering a vast field of disease from the extreme alkaline or strumous-tuberculous, to the extreme acid or rheumatoid-lithemic. And I have good reason to believe both have been accomplished, not only as to method, but also as to results.

Ere describing this method and its uses, it will be necessary to elucidate the course of reasoning traversed toward its attainment, from its inception through a study of the sun's rays and their influence to its present state of development. Sunlight produces kinetic and potential energy in the vegetable, the mineral and the animal kingdoms, all of which bear a sort of interchangeable chemical relationship to each other. The energy of the sunlight and heat is a force at least akin to if not identical with electricity in some or all of its forms. In fact, many scientists believe on very valid grounds that electric phenomena are the direct expression of the chiefest force in nature, the transplantation rather than the transformation of the solar energy itself. At least, it is a known fact that we can accomplish with electricity of exceeding high potential almost every phenomenon attainable by the sunlight, when the rays are concentrated sufficiently, high or low. First of all, we can create through electricity a luminous or incandescent condition, vastly less in degree but exactly akin to that of the sun itself. Moreover, a body so rendered luminous or incandescent acts on other bodies in a manner exactly parallel to the action of the sun. Furthermore, experiment, research and practice have demonstrated the perfect feasibility of the conveyance of potential energy to substances or bodies, living or dead, by electricity in a ratio approximating that of the solar planet. Almost every physical or chemical property of the sun and its forces has been reproduced in miniature by electric currents in some form. Even the storage of potential energy in plants and animals, or parts of these, has been accomplished in a manner truly analogous to that exercised by the sun itself. Just as vegetable and plant life unfolds itself and grows to the full in the light of the sun, so it can be made to unfold and grow in the light created by the voltaic arc.

From this basis a method of treatment has been deduced. It is perfectly practical, absolutely safe, and if I may judge of the results attained during the five years of most careful use and development (of the method), of much importance. It is to this method that I particularly desire to call your attention. Some of you know of, and a few of you may have witnessed, the work of Professor Finsen of Copenhagen, an actinic-ray treatment of certain dermatologic leisons, like lupus, first by means of the sun's rays through concentrating lenses, and later through powerful electric-arc lamps and lenses. So far as is known to me, Finsen and his followers have directed their efforts only toward skin affections, mainly lupus, it is said with excellent results, but at least with no more and probably with less effect than by the *x*-ray method. Others, among whom may be mentioned Mount Bleyer of New York, have attempted to cure constitutional maladies, like pulmonary phthisis, along much the same lines, or with static machines of great power and electrodes saturated with formaldehyd solutions placed on the chest or other affected part. Others again have employed electric-light baths, using ordinary incandescent globe-lamps, which are perfectly worthless.

Doubtless some of you recollect that a few years ago violet panes of glass were used with this same end in view. None of these methods has, I believe, given satisfactory results, mainly because they were not practically applicable; but the underlying principle of actinic action was correct, and these failures but serve to show that for many years there have been made efforts to secure some actinic method of worth. This method, I believe, I have elaborated to a point where not only general but also local actinism associated with nascent ozone is possible. By this means it seems to me an artificially created atmosphere akin to that of the mountain top, but richer even than this in actinic qualities and ozone and without the deleterious effect of altitude, has been attained. This, and the use of specially constructed vacuum conductors, without any terminals whatever, to be attached only to one pole of extremely powerful amplifying high-tension electrical apparatus for local application, are only the claims of uniqueness I make, so far as means and method are concerned. The claims as regards therapeutic results form another and distinct chapter.

The apparatus used is as follows: Picture to yourselves a large cabinet into which the nude body is placed in sitting posture. Behind and in front of the body projecting within the cabinet are powerful specially wound arc-lamps, the durability of which is sacrificed to their efficiency. On this cabinet and separated from it, is a sliding dome to contain the head of the patient. In this dome is placed a diffuse ozonating arc of peculiar construction. This latter is connected with a compound combination amplifying apparatus in one end of the cabinet, distinct from the space occupied by the body. From the amplificator certain wires run to poles to which the conductors for local use are attached. These conductors may be called electrodes with non-conducting exterior and a conducting interior, without terminal wires or plates. Such is the apparatus without entering into details of construction. When in use, the body of the patient is flooded with extremely rich actinic light. The body being nude, the penetrative rays not only bombard the surface, but pass through the epiderm to enter the blood corpuscles coursing beneath. That they do this would certainly seem indicated by the increase in per cent. of hemaglobin and the quick augmentation of the corpuscular elements. Under treatment there is usually profuse perspiration, but the body temperature has never been found raised beyond one-half degree, so that the effect is not a thermal one, but due to stimulation of the nerve-endings.

The head of the patient is protected from the intense light to which the nude body is subjected, partly in order to insure the safety of the eyesight. The air breathed is enormously charged with free ozone, or if desired, with formalozone or eucalyptozone, or with a combination which experience has shown particularly efficacious. Attention is drawn to the fact that these elements are in gaseous form and can, therefore, enter wherever air can penetrate. I have always regarded vapor inhalations as deficient, because no vapor-laden air can enter into the deeper-lying diseased lung tissues. This only gaseous substances can do. Whenever a local application is made a very remarkable phenomenon is shown. Not only does the conductive interior become luminous, but ozone in its most powerful triatomic form is driven into the tissues and remains in situ in nascent form to liberate free oxygen at any point toward which it is directed. This I have repeatedly demonstrated in living animal tissue. The conductors are constructed in diverse forms to suit the anatomic regions for which they are employed. Thus we have those for surface application, for the vagina, for the nasal cavity, for the larynx, etc. This is, in short, the method of usage.

Now as to the affections treated and the results thus far attained. At first I was in search merely of an actinic action to assist in the restoration of lost nerve energy in cases of neurasthenia and debility, such as come so frequently into my care at the sanatorium. Experience, however, demonstrated that the method had a vastly greater range of application than I had counted on, for complicating or causal affections were either improved or cured. For this reason I began to experiment with chosen cases of various diseased conditions, such as pulmonary tuberculosis, diabetes, syphilis, rheumatoid affections, as well as distinctly organic nervous affections, and the many localized conditions so often encountered in neurotic subjects, notably acute and subacute pelvic inflammations and exudates. Certain skin affections, like eczema and psoriasis, were also treated. It would require too much time to enter into all the details at this time. I shall content myself with a brief recital of the general results attained. During the six years in which I have employed this method a large number of cases have been treated, with an aggregate of several thousand treatments. There have been failures to record in some instances, but in the main this method has given excellent and some remarkable results. Several cases of pelvic inflammations and exudates have been completely cured, some only partially benefited. Many patients suffering from catarrhal, nasal and bronchial affections have been either entirely relieved or much ameliorated. In hay-fever and asthma the results have been especially good, both under complete and local application. Several extremely severe instances of these affections have been cured, or at least the attacks overcome without sending the afflicted individuals away from home. Two cases of widespread psoriasis of years' standing were very rapidly and seemingly completely relieved. In the treatment of locomotor ataxia and other constitutional nervous diseases, the results have been far more satisfactory than by any other method I have ever employed, and I think I have used almost every method of any worth whatever.

In all stages of uric acid and rheumatoid maladies, I fully expected distinct reaction to this method, for it is essentially one of oxidation. The profuse perspiration which nearly always accompanies the actinic treatment is naturally of the greatest value whenever faulty metabolism exists, and when this is directly influenced by oxidation of the deposits and consequent solubility of substances known to act deleteriously on the system by their toxic character, it could fairly be surmised that distinct benefit to the patient would result from their elimination. Experience has shown that my expectations were completely realized. Several severe cases associated with marked nervous symptoms were entirely relieved, while milder forms recovered with comparative rapidity. It must be remembered that we deal in such conditions with an actual loss of oxygen in the molecular composition of uric acid, $C_5H_4N_4O_3$. By restoring the oxygen in nascent form solubility is recovered.

But it has been in neurasthenia and other debilitated conditions, that the best results were attained. The results have been almost uniformly excellent. A large number of cases have been treated during the past six years, and there have been few, if any, failures to report. While in every instance the general treatment, as outlined before, has been followed out, it has frequently been necessary to overcome certain local or causal manifestations by means of local actinic applications. This is especially true as regards the neurasthenic aches and pains along the spinal column and in other regions of the body.

Not only have the individual results been good, but the duration of treatment has been materially lessened, in some cases fully one-half. This is clearly evidenced by a comparison of the period during which patients remained at the sanatorium before and since the inauguration of this method at "Norways."

The most gratifying results have been attained by this method in pulmonary tuberculosis. I am fully aware that in making this assertion I am treading on ground which has been for years worked on and in which some glowing medical failures have been a matter of record. Nevertheless, I am prepared to assert positively, and hope eventually to prove by future results, that in all cases of lung tuberculosis where the disease has not advanced too far, complete cure will result from the proper methodical use of the actinic method. The cases heretofore treated, while not a few in number, may still be considered insufficient to bear out my claims in the minds of the profession at large, for we are all naturally skeptical whenever a new cure, however positively stated and no matter how reliable the source, is called to our attention. To my mind, however, a dozen cases carefully followed out, both clinically and pathologically, with careful blood and sputum examinations at frequent intervals during the course of treatment, are as reassuring as a hundred, where the results gained are so eminently complete.

In the cases of phthisis heretofore treated, these results have been as follows: In every incipient case and in every case where the process had not passed beyond what is commonly termed the first stage, there has not been a single failure to record. Almost from the commencement of treatment a noticeable improvement showed itself. Expectoration and cough—which at first may be augmented for a time—decreased, appetite and weight increased in spite of often profuse sweating during the ten to twenty minutes of body exposure, and gradually the physical weakness disappeared. In from ten days to three weeks the blood examinations revealed a notable increase in the number of red and white corpuscles, sometimes multiplied several times. The per cent. of hemoglobin increased markedly. The sputum grows thinner and more profuse at the start, but gradually decreases in volume, with a corresponding decrease in the number and final disappearance of tubercle bacilli and other micro-organisms of mixed infection. It is to the septic influence of the latter that so many of the associated clinical symptoms of consumption are due. In fact, I wish here to record the decided opinion that tuberculous affections *per se* are not nearly so dangerous or so fatal as the profession believes. Nor is pure tuberculosis a febrile disease. It is only where there is a mixed infection with the germs of ordinary sepsis that fever obtains, that rapid advance in the malignant process occurs; and usually here only that we meet with a fatal end. Unfortunately, this mixture of infection usually takes place. It is in overcoming the complicating septic condition that gives this method its greatest value and permits the restoration of the wasted energy to these patients. It is unnecessary to further speak of the immense advantage thus gained toward the extinguishing of the tuberculous process itself. Patients suffering from more advanced stages of tuberculosis were much benefited, and some seemed on the verge of recovery, but continued to manifest distinctly characteristic symptoms.

I have tried this method of treatment in cases of far-advanced phthisis with cavity formation. Only the complicating symptoms were relieved, especially when formo-eucalyptozone was used. Cases with strong tendency toward hemorrhage are probably unfit for this method of treatment, though no bleeding of magnitude had occurred under my observation. I have been careful to select the cases and have not allowed anyone I considered a dangerous subject to be treated. However, I have shunned no case of pulmonary tuberculosis which I felt might be cured by a long sojourn in Colorado or elsewhere, and in several instances I have taken cases into treatment which I should not have risked sending into high altitude. It is to the absence of altitude that this method owes its absolute safety. Everything else that the condition of the Colorado mountain atmosphere gives, seems to be abundantly supplied by the actinic rays of light and the free ozone.

In addition to the general treatment as previously described, local applications on the chest over the affected areas in the lungs were invariably given with a view toward sending ozone, in nascent form, directly into the diseased tissues by means of the glass electrodes. Nascent ozone is an extremely active germicide, and in addition liberates free oxygen *in situ*. Doubt will probably be expressed as to anyone's ability to send nascent ozone into any given part of the deeper tissues, on the ground that electric currents diffuse themselves along the paths of least resistance beneath the skin. This is quite true for ordinary currents, and to a lesser degree of this method also. The currents used are, however, of such high potential, and as the actinic rays travel along approximately straight lines after deliverance, the usual rule does not apply here. Experimentally, I have sent ozone into animal tissues and found its presence there by chemical reaction. It is a common comment of patients thus treated that they can taste the peculiar effect of the ozone in the expectoration long after the external application has been made. Nor does the effect of this treatment seem evanescent or lacking in ultimate permanency, for those patients who had recovered showed no marked tendency to relapse, even where they were not as cautious as they should have been.

Some of you may very reasonably ask why I do not give full statistics of all cases treated during these years. My reasons for not giving more detailed statements regarding them are two-fold. First, too much time would be consumed thereby, and, second, they would be questioned no matter how complete they might be. Everything savoring of newness and importance in the medical world is with perfect justice regarded with skepticism by our profession at large, in part because the enthusiasm of investigators and observers so frequently carries them too far. I have tried to be as conservative and moderate as I feel the importance of the subject and the results heretofore gained would warrant. As remarked before, what the actinic method as here described accomplishes after this perfectly frank statement of its worth, as I and others regard it, must be the sole criterion of its value and utility.

## SUMMARY.

To summarize what has been brought forward to-day, I conclude:

1. Actinic rays are chemical in their quality, but of small caloric value.
2. They exist mainly in the ultra-violet zone of the spectrum.
3. Actinic rays derived from high power electric lights are similar to or identical with those of solar origin.
4. Their use is as rational as that of sunlight itself.
5. Their value lies in their decomposing, but at the same time reconstructive molecular action on the body tissues, mainly the blood elements.
6. By the method herein spoken of their activity is enhanced by the generation of ozone in free and nascent form.
7. Their ultimate effect is one of oxidation, and consequently they increase the metabolic changes, thereby augmenting the natural processes of regeneration within the system.
8. The germicidal action is especially pronounced on account of the fact that few germs can exist in the presence of free or nascent oxygen in either biatomic or triatomic form.

## DISCUSSION.

Dr. D. I. Wolfstein, Cincinnati—How long has this treatment been used, and what is its general effect on diseases of the nervous system?

Dr. John Punton, Kansas Cty—If Dr. Sterne has succeeded in finding a method that will cure these cases of neurasthenia he has conferred a great benefit on mankind and the medical profession. I am glad to hear that he has not had any failures.

Dr. William J. Herdman, Ann Arbor, Mich.—There is no doubt a physical explanation of the action of the nerve cells. At our Denver session I presented a paper on the dynamics of the nervous system, and I am glad to find that an independent course of thought has run nearly parallel with my conception of what takes place in the nerve cell, both physiologically and pathologically. I doubt if we will ever fully explain this to ourselves—this complex problem of the constitution of the nerve cell and its activity. Dr. Sterne is getting exactly the same results from the actinic rays that are secured from the high-frequency current in many of its forms, which were demonstrated years ago by Brown-Séquard and others. We all know that the simpler forms of the electric current have certain physical effects on the organism. It will produce physiologic contraction of contractile tissue. It will also cause a movement of the fluid constituents of the organism from one part of the body to another, in the phenomena which we term cataphoresis. This is done by means of the direct current. The indirect current, in the form of the induction coil, also has a wide range of usefulness, largely due to the difference of potentiality and the frequency with which the interruptions take place. Those are what we term the gross effects. Now, when you begin to increase the potentiality and the frequency of the alternations, you reach a point where nerve tissue, as such, can not respond or where protoplasm or muscular tissue can not respond. About ten thousand alternations per second is the limit. But the alternations of the high tension, high-frequency current run up into the hundreds of thousands. We know very well that molecular activities, either organic or inorganic, are almost infinite in the number of vibrations that may take place. In these glass tubes, such as the one shown by Dr. Sterne, the molecules are bombarded to and fro, and this molecular action is directed by the electric current. Some are positive, others are negative, and they are changed in their direction by reason of their polarity. Why not assume that the same thing is going on in the molecular activity of every cell organism of our body? The little molecules that make up a nerve cell are continually undergoing these vibratory motions. It is this activity that produces what we know as vital action, and by employing an apparatus like this we are getting to a point where we have a process which we can apply and which will adapt itself to those molecular movements. It shows that we have something or other which is modifying the nutritional activities in the molecular field. Whether or not we have heard the true explanation from Dr. Sterne to-day I do not know. I have used this method in various conditions of the skin and other parts, but not in the manner he has described. There is no doubt, however, but that we can control nutritional activity better in that way than in any other. I feel that I have a therapeutic agent in the high-frequency current that fully meets the requirements.

Dr. C. C. Hersman, Pittsburg—What effect can we expect from the high-frequency current beyond the point where muscular and nervous tissues fail to respond to its stimulus?

Dr. F. W. Langdon, Cincinnati—Dr. Herdman's statement, if I understood it correctly, was that there was no effect on muscular contraction, but that there may be a marked effect on metabolism without visible contraction.

Dr. A. E. Sterne—I have brought up this subject after five years' careful work in this field. The work is still incomplete. I do not entirely understand these phenomena, which I have repeatedly seen demonstrated. I understand the application thoroughly, but I can not explain the demonstration. In acute coryza, with the nasal cavity almost completely occluded, the application of these rays will act exactly like cocain. It will cause tissues to shrink, and I have seen exudates in the pelvis disappear under the action of this tube with the alternating current passing through it. It apparently sets the mass into molecular action, and thereby results in such an amount of energy as to bring about a natural absorption through the circulation.

# SOME TOXEMIAS IN RELATION TO THE PRODUCTION OF NERVOUS AND MENTAL DISEASES.*

SAMUEL BELL, M.D.

Superintendent Lakeland Private Hospital for Nervous and Mental Diseases, Grosse Pointe, Mich.
DETROIT, MICH.

There is to-day no specialty in the field of medicine which presents more difficulties and dissensions among alienists and other scientific investigators than the satisfactory diagnosis, comprehension and treatment of disorders relating to the nervous system. Although more than two centuries have elapsed since Hippocrates prepared a foundation for the science of psychiatry, a rational and universally acceptable conception of diseases presenting symptoms referable to disorder in nerve structure or function, has not been reached.

It can not be denied, however, that, when the cause of a certain morbid process is discovered, the treatment of the case can be made more rational and effective. If we as clinicians, would be more thorough and studious in the consideration and investigation of a case, instead of treating it along general text-book rules, the treatment and progress of the disease would resolve itself into a more rational and less difficult problem.

I am in hearty support of less empiricism and of more rationalism in therapeutics. It is often found necessary and more convenient to treat certain disorders symptomatically, but in my chosen specialty I have gained more satisfactory results, through a careful study of the patient as a "whole," than, so to speak, "in parts."

A comprehensive and working knowledge of physiologic chemistry, bacteriology, pathology and physical diagnosis must aid our clinical experience.

### AUTOINTOXICATION AN IMPORTANT FACTOR.

Before carrying out the systematic treatment of nervous and mental cases brought to my attention, I ascertain, so far as can be determined, the condition of the various organs and functions underlying the vital processes, and I may safely assert that in general, I have been able to discover at least one organic or functional disorder in the individual, which, if rectified, helped to facilitate a correct diagnosis, treatment and the ultimate recovery of the case.

And this leads us to a concise discussion of the subject of autointoxication as a factor in the production and prolongation of certain nervous and mental manifestations, together with a few words on the development of autotoxemias resulting secondarily from the introduction of poisons of external origin into the otherwise healthy organism.

The views I will here set forth have been gained from practical experience during the past ten years, aided and stimulated by the opinions and observations of other interested workers in this field.

Bouchard and his pupils deserve much of the credit for the widespread interest and practical results which have arisen through a study of autointoxication. Although the statements and theories elucidated by him have not all received acceptance and substantiation, he has prepared the way for a broader and more rational conception concerning the causation of disease in general, and of nerve and mental disorders in particular.

### WHAT IS AUTOINTOXICATION?

The conception of autointoxication is not merely an attractive hypothesis, since positive facts have been brought forth in defense of this theory, and new evidences are being adduced from the field of physiologic chemistry, physiology, pathology and bacteriology, thus lengthening and tightening the already large chain of evidence. The accepted definition of autointoxication is a poisoning of the organism by the products of its own metabolism, which substances may be either normal in character, but abnormal in quantity, or abnormal in character.

I wish to state in the beginning that I do not agree with the extremists who strive to ascribe nearly all diseases of nervous origin to autotoxins of some kind or other. In many cases other processes are undoubtedly the productive factors, such as mechanical injury to nerve structures, pressure from tumors, the transmission of a hereditary tendency towards incomplete or defective cell growth or function, etc. The subject is a most difficult and comprehensive one, and we can not be too cautious in accepting conclusions favoring our theory, hastily, and without facts to substantiate the same.

### FORMATION OF AUTOTOXINS—LEUCOMAINS.

Bouchard aptly says that the human body is both a receptacle and laboratory of poisons. These are found in the food, are formed during the processes of normal digestion, are formed in the tissues and fluids of the body, and still the healthy individual is not poisoned. There are continually being formed in the body, under normal conditions, certain products resulting from metabolic processes, and if these accumulate in large quantities, disease may result. These substances have been termed leucomains, products formed in the tissues, not through the intervention of bacteria, but through fermentative processes or retrograde metamorphosis. Leucomains are basic in character, but their unstable constitution makes it evident that the isolation and identification of these products from the blood and tissues, and their injection into animals for the purpose of eliciting symptoms of poisoning, is a most difficult problem and often impossible of accomplishment.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

The leucomains have been divided into the uric acid and the creatinin group, the xanthin bases being representative of the former. The excretions of the human being are toxic, even though the individual partakes only of chemically pure, and bacteria free, air, water and food. These poisons must originate somewhere, and scientific investigation has traced their origin to substances resulting from the disintegration of cells, *namely, leucomains*. The hydrocyanic radicle is found as a frequent constituent of the leucomains, which may explain a portion of their poisonous action.

While certain organs or cells are occupied in manufacturing poisons, others are engaged either in arresting and excreting these poisons, or in chemically changing them into useful or harmless bodies. On these organs of defence, therefore, rests the responsibility of so disposing of the poisons continually being formed in the body, that the latter may become innocuous to their deleterious action. These organs of defense perform their duties faithfully when all the bodily functions are acting normally and in harmony, and when no excess of noxious matter is introduced from without.

Thus autotoxemias as a rule result from some disturbance between the formation and the destruction or excretion of these internal products of metabolism, there resulting an accumulation of these products in the tissues and circulating fluids. It is the function of certain organs, therefore, not to make it possible for enough toxic material to accumulate in the blood to give rise to systemic disturbances, either acute or chronic in nature.

### ORGANS OF DEFENSE.

These organs of defense have been divided into two kinds—those of transformation or arrest, as the liver, gastrointestinal mucous membrane, spleen, lymph glands, adrenals, thyroids, etc. These possess the power of opposing the various foreign and poisonous substances brought to them by the blood and lymph, and of converting them into non-toxic and non-assimilable bodies, or of filtering out and rejecting them entirely, as represented by the liver and its secretion, the bile.

Then we have the organs of elimination, such as the kidneys, lungs, intestines and skin, whose duty it is to remove from the circulating fluids such toxic substances as either escape the organs of arrest or are formed later in the muscles and other tissues.

The present conception of autointoxication is therefore dependent on a disorder of the normal metabolic processes above described, and undoubtedly it supplies a reasonable explanation regarding the origin of many complex neuroses hitherto left unexplained.

### PRODUCTION OF STRUCTURAL ALTERATIONS.

That structural alterations are produced in the various organs of the body by the continuous action of these poisons of internal production, especially on so delicate a structure as the neuron, has been conclusively proved. Pathology has demonstrated the retrograde metamorphosis resulting from the action of mineral and vegetable poisons on the organ and cell, and the more recent work of Van Gieson and others has shown us the destructive effect of certain autotoxic poisons on the nervous structure. He has very aptly compared the brain to the kidney in the reaction of its organic constituents and functional power. The renal stroma is likened to the neuroglia, and the parenchyma to the nervous system, and it has been conclusively established that toxic products elaborated through the action of autotoxic bacterial and other external agents, do produce such cell and functional changes.

Autopsies have clearly demonstrated that acute parenchymatous degeneration of the brain caused by toxic agents explains the secondary factor in the causation of many acute mental and nervous diseases, while the subacute and chronic forms are due to a more extensive alteration in the neural parenchyma, caused by the prolonged action of these poisons. For instance, a cortical cell has a well-defined minute structure and function, the granular constituents being the reservoir of cell energy. When death has supervened from secondary causes after severe epileptic convulsions, these cell granules are found to be altered, being broken up through the action of abnormal or toxic substances, the functional indication being an uncontrollable and violent explosion of nerve force in the form of convulsions. If these toxic agents can be removed or decreased, through proper treatment, the cell resumes its normal function; if prolonged, the nucleus and then the entire ganglion cell and characteristic function becomes disintegrated and beyond repair.

### VARIOUS SOURCES OF AUTOINTOXICATIONS.

Inasmuch as the majority of nervous and mental disturbances due to autotoxemias have been found to owe their origin primarily to the stomach, intestines, liver, kidney and various glandular organs, only brief mention will be made of other sources of intoxication, as the lungs, skin and circulatory apparatus, the latter reacting more often to toxins originating in the former class. Autointoxications may also occur primarily from disturbed metabolism in the lungs and skin. We will not include the many disorders resulting when the lungs become primarily diseased in structure and function, through bacterial agencies, such as tuberculosis, etc., in which a distinct toxin is formed by a germ and exerts a deleterious influence on the nervous mechanism.

### AUTOINTOXICATION FROM SKIN DISORDERS.

Likewise the skin may present exanthemata indicative of a disturbance originating in some other organ, as the alimentary canal and kidneys. I have frequently observed eczematous conditions in chronic nephritis, which improve or disappear as the kidney functions progress under proper treatment. The formation of blebs, urticaria, itching and tingling eruptions, etc., yielding readily to regulation of the alimentary canal, may be observed; but these manifestations must of course be classed as secondary phenomena of a primary autotoxis elsewhere. The lungs and skin may, however, be the primary mischief makers. When placed under improper hygienic conditions, atmospheric and other changes, the lung cells, and in case of the skin, the oil and sweat glands, may not functionate properly, and the various products of disturbed metabolism and the excretory substances may be reabsorbed into the organism, reacting in excessive amount on the nerve elements.

### TOXICITY OF SWEAT.

That human sweat is toxic, there can be no doubt, inasmuch as it carries with it waste products from the circulation and tissues. Arloing has performed some experiments on the toxicity of human sweat on the lower animals. He finds that it exerts a depressing influence on the circulatory and respiratory organs, stimulating the vomiting center in the medulla and also causing cachexia. He has found sweating a valuable agent in overcoming autotoxic conditions.

### DISTURBANCES IN BLOOD AND CIRCULATION.

A functional inactivity of the nerve and gland terminals in the skin may result from a prolonged action of the retained products of its own secretion and excretion, which may exhibit itself both in trophic and inflammatory disturbances local in character or more systemic through reabsorption. A disturbance in the function of the circulatory apparatus, and especially in the composition of the blood, is both a starting and distributing factor in the origin of autotoxemia. Thus deficient nutrition to the cell, resulting in the production of toxic products from the impaired metabolism, will follow. A persistent tacycardia may be present, while other toxins may have an opposite action in slowing the pulse, probably through their action on the cardiac centers in the medulla, or else directly on the cardiac ganglia themselves. The selective action of certain drugs and poisons for certain centers and tissues alone, leaving other structures undisturbed, is a well-established physiologic observation; autotoxins which either increase or slow the heart rate may have their analogue among vegetable poisons, as in atropin and muscarin. Other anomalies of the circulation are iregularity of the pulse, flushing of the skin, cyanosis, coldness of the extremities, etc. Many of these symptoms may be due, of course, to the action of poisons formed in the various organs, as well as to those originating primarily from a disintegration of the red and white cells and other blood dyscrasias.

Time will not permit me to discuss the action of detrimental products which may result from a changed metabolism in the various glandular organs, such as the spleen, adrenals, lymphatic glands, etc., and I will therefore content myself with a few remarks concerning the salient features of thyroid disturbance.

### AUTOINTOXICATION FROM THYROID DISTURBANCE.

The employment of thyroid extract in certain nervous and mental disorders furnishes another link in favor of the autotoxic theory. The thyroid gland pours its colloid secretion into the circulating fluid, and when this is either altered in quantity or quality certain nervous and other symptoms develop, pointing towards a disordered metabolism in the gland. The two theories most widely accepted and substantiated, relative to thyroidal function are, that it either furnishes a secretion essential to normal metabolism, or that it pours some chemical substance into the organism, which acts as an antitoxin to the poisons formed and liberated during metabolic action, and changing or destroying deleterious substances circulating in the blood.

### IMPORTANCE OF THYROID IN METABOLISM.

The effect of thyroid extract on metabolism has been conclusively established by Baumann, Horsley, Hutchinson and many others. Laboratory experiments have demonstrated that extirpation of the thyroids and parathyroids in animals, results in characteristic nervous manifestations, convulsions, paralysis, cachexia, dyspnea and death. It has been observed that the thyroid glands are often atrophied in certain nervous and mental troubles, and this led to its employment as a remedial agent. In the palliation and removal of certain systemic disorders no more brilliant results have been obtained in internal medicine than by the administration of this medicament when rationally indicated.

The employment of thyroid extract in cachexia thyroepriva, myxedema and cretinism, has given wonderful results. The cachexia, weakness and heaviness in the limbs, dulness of tactile sensations, retardation of muscular action, difficulty in thinking and general decrease in mental and intellectual power, are all either dispelled or greatly improved while administration is continued.

Poehl has performed experiments showing that spermin is found in the thyroid, pancreas, testes, etc., and is at least one of the agents which maintains the oxidation powers of the organism at normal height. In the case of the thyroid secretion, however, it has been practically demonstrated that an organic iodin compound is the active principle. When this latter is isolated from sheep glands and administered to animals on whom thyroidectomy has been performed, there ensues very soon a subsidence of all the nervous symptoms.

Many investigators as well as myself have employed the extract where a disordered or arrested metabolism has been considered to have resulted from disturbance in the thyroidal secretion, with the utmost and surprising and successful results. I have obtained very beneficial effects from its employment in stuporous conditions, melancholia and mania.

### A CHEMICAL AND PHYSIOLOGICAL STUDY OF THE URINE IN HEALTH AND DISEASE.

A chemical and physiological study of the urine in health and disease adds corroborative proof to the theory that normal urine is toxic. Laboratory experiments have also demonstrated an excess of toxic material excreted in the urine during and immediately following retrogade cell changes. Bouchard has demonstrated that urine secreted during the hours of activity is more toxic than that secreted during rest. . In toxemias there naturally exists a tendency to accumulation of waste products in the body, and a study of the urine therefore offers a splendid field for investigation of the toxic products and the possible reason for their appearance and locality of their origin.

### POISONS IN NORMAL URINE.

Although all of his experiments have not been corroborated, it is generally agreed that normal urine contains at least seven isolated poisonous principles which he has experimented with on the lower animals. These consist of a diuretic, a narcotic, organic and soluble in alcohol, a sialagogue, also organic and soluble in alcohol, two convulsants, one organic and insoluble in alcohol, the other a mineral, potassium, a myotic, organic in nature; seventh, a temperature lowering principle, organic, insoluble in alcohol, diminishing heat production.

### EXPERIMENTS WITH URINARY POISONS.

He performed extensive experiments on animals, administering through different channels varying amounts of both normal and abnormal urine, as well as each of the seven isolated products, eliciting characteristic symptoms. All of these principles have as yet not been definitely analyzed, and beyond any doubt both normal and abnormal urine contain still other toxins as difficult of isolation and analysis as are the tetanus and other bacterial toxins.

### PUERPERAL ECLAMPSIA.

The most plausible explanation of the exciting cause of puerperal eclampsia is that of an autotoxis. During pregnancy there is certainly a greatly disturbed metabolism, and when the waste products are held back by the excessive work thrown on them, as shown by the frequent occurrence of albuminuria, the retention of these katabolic agents will account for the severe epileptiform attacks. Impaired elimination of the convulsive principles would be also sufficient to produce eclampsia. Von Jaksch has done some work along these lines, and has shown the convulsive effect of acetone and its presence in the urine during the later stages of pregnancy. He even goes so far as to describe a typical "eclampsia acetonica."

### URINE IN EPILEPSY.

An examination of the urine in epilepsy has developed some valuable facts. That certain otherwise unexplainable forms of epilepsy are due to poisonous products of disturbed metabolism is the present consensus of opinion of Futcher and other interested investigators. Experiments showed that the urine of certain epileptics is hypertoxic about the time of the attacks, its tenacity being much greater than during the interparoxysmal period. Deutsch, Jaksch, Wyner, Kranisky and others report cases of epilepsy due to the periodical formation of acetone and ammonium carbonate.

Hippocrates was the first to relate the fact that the intercurrence of an infection or fever frequently suspended epileptic attacks for a time. Bourneville. Toulouse, Marchand and others have written careful observations concerning the most common infections, which have suspended epileptic attacks for a time, some cases being permanently benefited. *Pneumonia*, erysipelas, malaria and typhoid fever have been found to result in benefit to the primary disturbing disease process. An explanation for this might be that during the occurrence of these infections, bacterial toxins acted detrimentally on the cell structure, katabolic processes resulting thereby. During recovery from the infection, anabolic processes resulted; the cell was rebuilt and returned to a more normal condition. The toxin which originated epileptic attacks during the primary disordered metabolism, was thus either neutralized by or eliminated with the bacterial poison.

### URIC ACID DIATHESIS.

A study of the urine in neural disorders would not be complete without a reference to the uric acid diathesis. I have found an increase of this excretory product in the blood and urine of many cases under my supervision. An increase of this leucomain is discovered to be the disturbing factor in many forms of disordered metabolism. Uric acid is closely related to the xanthin bases, and both are derived from the nucleins contained in the cell protoplasm. The xanthin bases result from a decomposition of tissues rich in nuclein; but the nucleins must first be partially oxidized before being decomposed in order to split off the uric acid.

Uric acid must therefore be considered as a specific waste product of nuclein decomposition. The term "collemia" has been applied to the presence of large amounts of uric acid in the circulation. An excess of uric acid has continually been observed in such disorders as neurasthenia, migraine, epilepsy, chorea, etc., especially immediately after the attacks.

We have here a clear demonstration of an autotoxemia, a nutritional disturbance resulting from faulty metabolism, brought on by unhygienic influences, errors in diet, excessive consumption of alcohol and nitrogenous food, etc. As resulting symptoms, we see headache, neuralgia, melancholia, lack of thought concentration, depression, mental irritability and excitability. The benefit obtained following the neutralization or elimination of the excesssive uric acid, strengthens the conclusion that this is the disturbing waste product.

### RELATION OF DIABETES TO AUTOTOXEMIA.

Certain forms of diabetes are among the concomitant manifestations of neurotic disorders. Where no other definite causes can be disclosed, it can be reasonably suggested that there is present a faulty metabolism located especially in the pancreas, so that the glycolytic ferment is not properly poured forth as regards quality and quantity. Dependent on this, the glycogen can not normally be assimilated into the organism. Extirpation of the pancreas in animals results in glucosuria, which strengthens our belief that the pancreas pours a glycolitic ferment into the circulation. There is certainly present an extensive disturbance in cell function, as shown by the large increase in the urine, of b-oxybutyric acid, aceto-acetic acid and acetone—all evidences of increased protein destruction. The presence in the circulating fluids of these bodies may account for many of the neurotic symptoms, as headache, neuralgia, numbness, delirium, and the symptoms of *diabetic coma*, somnolence, dyspnea, etc.

The similarity of the attacks to uremia would indicate the presence of some autotoxin in the blood. The most widely accepted theory that this substance is acetone, is substantiated by the presence of large quantities in the urine and its odor in the breath. The fact must not be ignored, however, that the preliminary poison causing a disturbance in the pancreatic metabolism may originate from poisoning through intestinal toxemia.

### UREMIC AUTOTOXINS.

Uremia is undoubtedly the result of an autoxemia, but what the toxic agent is and how it acts has not yet been satisfactorily demonstrated. The symptoms which may occur in uremia, such as convulsions, headache, restlessness, delusions, maniacal and melancholic states, local paralyses, itching of the skin, numbness, tingling in the fingers, etc., are all suggestive of a toxic agent as the malefactor.

Bradford, in his Goulstonian Lectures for 1898, has gone into the subject of uremia extensively, and comes to the conclusion, deduced from careful laboratory and clinical experience, that the toxic substances which are present are not the retention products resulting from normal metabolism, but that there is formed an abnormal product of a disordered metabolism, which is poured into the circulation. What this substance is, investigators have not as yet fully agreed upon. It has been found that the percentage of urea is greatly increased in many cases of chronic nephritis with uremia, but it is probable that more than one toxic agency is at work, to account for the formidable symptoms developed. Here, again, as in diabetes, poisonous products absorbed through intestinal toxemia may originate the manufacture of the uremic poison.

### THE GASTROINTESTINAL CANAL A FREQUENT SOURCE OF AUTOINTOXICATION.

The gastrointestinal canal is the most frequent source of autointoxications. As a result of disorder here, ptomains and other products may result, which, in turn, after absorption, may be the starting point in the manufacture of leucomains, if they themselves are not directly the irritating agents. The production of fermentation and putrefaction, the former mainly in the stomach and the latter in the intestines, results in many of the human ills and nervous wrecks which our congested civilization exhibits. The gastric fermentation follows the excessive ingestion of carbohydrates, while putrefaction depends on the presence of albuminous bodies for its existence in the intestinal tract.

### AUTOTOXINS IN GASTRIC FERMENTATION.

Among the deleterious products formed during gastric fermentation, which, if absorbed, may disturb normal metabolism, are lactic, butyric and acetic acids. The intestines, however, on account of varied ferments and the presence of albumins which favor the multiplication of the anaërobic bacteria and their products, furnish the most varied number of toxic principles harmful to the organism after absorption. Extensive experiments have been conducted in the isolation and investigation of these agents and their subsequent injection into animals for the purpose of eliciting toxic symptoms. Foremost among these investigators are Brieger, Selmi, Gautier and Buchner.

Among the substances found following albuminoid putrefaction. may be mentioned ammonia, cystin, hydrogen sulphid, leucin and tyrosin, representative of the amido acid series; a group of aromatic bodies, derivatives of benzol, phenol, cresol, indol, skatol, etc.; diamins, such as Brieger's cadaverin and putrescin. The latter brings us to a discussion of the ptomains, the most important products resulting from intestinal decomposition. A ptomain may be defined as an organic chemical product, basic in character and formed by the action of bacteria on nitrogenous matter. Although these ptomains result from saprophytic action, disturbances following their absorption may still be classed as autogenous, since the lower forms of vegetable life which act on the albuminous contents of the intestine are normally present during the life history of the human organism.

### WHAT ARE PTOMAINS?

The name ptomain was first applied by Selmi to these organic basic substances. They may be called the putrefactive alkaloids. Not all ptomains are poisonous, however. He performed extensive experiments and demonstrated the fact that animal alkaloids quite similar in constitution and action to those from the vegetable kingdom, might be produced in cadavers as well as in the intestinal canal. Many of these ptomains resemble in chemical reactions strychnin, atropin, morphin and other vegetable alkaloids. During a celebrated trial in Italy, where the prosecution endeavored to make out a case of strychnin poisoning, the prisoner was acquitted on the testimony of Selmi that the base present was cadaveric in origin.

### EXPERIMENTS ON LOWER ANIMALS.

Many experiments have been employed on the lower animals for the purpose of eliciting, if possible, symptoms similar to those observed in intestinal toxemias. I can not enter into a description of the many investigations carried out along this line, though careful observers have demonstrated that autotoxins isolated from the alimentary canal cause symptoms similar in animals to those observed in human beings. Treatment further demonstrated that the removal of these toxic products resulted in a cessation of symptoms of disorder. The intestinal excrements were extracted with various reagents, and after purification so far as possible, the various constituents were administered to animals through different channels.

The absorption of indol is responsible for many of the disorders referable to intestinal toxemia. Herter has performed some interesting experiments with this substance. When given in continued doses to a rabbit, for some time, emaciation results. When a solution of indol was injected into the animal's intestines there resulted contraction of the pupils, muscular twitching, cardiac weakness, feeble respiration and general depression. Three men took small doses of indol for experimental purposes, beginning with 1 gr. Dull headache resulted. Larger doses produced severe colic and diarrhea in one. Another experienced great discomfort, intestinal flatulence, headache and insomnia. The third had the same symptoms, only more severe. The reaction for indoxyl and the ethereal sulphates was greatly increased in the urine. All of the cases showed exhaustion.

A study of the urine naturally confirms the absorption of intestinal toxin, inasmuch as after their absorption, they are more or less transformed in the body, and then increased elimination of the end product above normal occurs in the urine. The presence of various foreign substances in the urine may therefore lead to the discovery of their method and locality of production. The presence in comparatively large amounts in urine, of benzoic acid, the ethereal sulphates—indoxyl and skatoxyl, phenols and cresols, cystin, leucin and tyrosin, acetone, aceto-acetic acid, b-oxybutyric acid, etc., all refer to some alimentary toxemia or a disorder in metabolism directly referable to it. Singer has found almost regularly, in skin diseases associated with digestive disturbances, an increase of the putrefactive products absorbed, as shown by the excretion of an increased amount of ethereal sulphates in the urine.

Space will allow the discussion of only several alimentary disorders which have been clearly proven as the irritating influences in the origin of many nervous and mental disorders, especially those of a neurasthenic and hypochondriacal character. I will refer briefly to the so-called nervous dyspepsia, dilatation of the stomach, and constipation.

### NERVOUS DYSPEPSIA.

Nervous dyspepsia is a form of indigestion marked by the manifestation of nervous and other symptoms directly referable to gastric disorder as the instigating factor. There is usually present a feeling of malaise, headache, dizziness and insomnia. Hysterical and neurasthenic symptoms may appear. The etiologic factors at the base of this can very often be directly attributed to faulty hygiene and errors in diet. As a result, too much work is thrown on the stomach, and there results either an increase or decrease, or entire absence of free hydrochloric acid to carry on normal digestion. Thus an interference with nutrition follows, and gastric digestion is either carried too far or not far enough, as a result there being an absorption of these sub-end products of gastric digestion. These in turn may be the starting point in the manifestation of nervous symptoms, directly or secondarily through the production of leucomains.

As a result of fermentation, lactic and butyric acid, eructations of gas, etc., may take place, due to the work thrown on the digestive organ. These products after absorption are responsible for the headache and oppression.

Peptones and albumoses formed during digestion do not normally reach the general circulation as such. Injection of these substances into animals lowers blood pressure, depresses the heart, and destroys the coagulability of the blood. Lauder Brunton attributes the weakness, languor, dullness in the head and depression after a full meal to poisoning with peptone. Its detection in the urine proves its entrance into the blood.

### DILATATION OF THE STOMACH IN NERVOUS DISORDERS.

Dilatation is frequent among the gastric disorders productive of nervous symptoms. Errors in diet are again the main causative factors. A diminution in mental and physical vigor ensues. Among the characteristic symptoms are headache, insomnia, vertigo, undue sensibility to cold, and in one case which I have observed especially, during the morning hours there was a confusion of ideas, incoherence and obscuration of sight. A study of the urine showed an increase of urates and acidity, and the presence of peptones. Among intestinal disorders, constipation is foremost in favoring the production and absorption of toxic products. The term copremia has been applied to this condition, and the symptoms characteristic of this are well known, such as dizziness, lassitude, headache, insomnia, hypochondrias s, neuralgias, etc.

The majority of these symptoms are probably due to the absorption of the putrefactive products arising from the retained feces. This is demonstrated by the increased transference of the products of putrefaction to the urine. Chemical examination of the urine discloses the presence usually of indican.

### TETANY AN AUTOTOXIS.

The history of tetany can usually be traced to some gastrointestinal disorder, and Albu, in his admirable discussion on this subject, asserts this disease to be a most brilliant example of a gastrointestinal autointoxication. Most of the cases may, if carefully investigated, be traced to some form of gastritis, acute or chronic, dilatation of the stomach being the most common disturbance. Albu obtained from the urine of certain cases the salt of an alkaloidal-like body, which was always present during tetany attacks, but never during free periods. The injection of this in animals produced an artificial tetany.

### AUTOINTOXICATION FROM SEPTIC DISORDER.

Autointoxication from the gastrointestinal tract is closely related to poisoning directly referable to the liver. Self-poisoning may take place either from a disturbance of the liver parenchyma itself, by poison generated within itself, or through the secondary action of poisons received from the intestines, which may enter the circulation without the protective and destructive action of the hepatic function being exerted.

In consequence of interference with hepatic function, carbohydrates are not properly stored as glycogen, the formation of urea, the best diuretic, is interfered with and the antecedent bodies of the amido acid series, leucin and tyrosin, are excreted into the blood, as shown by their detection in the urine. Various hepatic disorders, such as atrophy and cirrhosis, may interfere with its normal function. Cholemia is a fruitful source of nervous manifestations, and results when the constituents of the bile are passed into the blood. Following the absorption of bile salts and coloring matters (bilirubin) into the blood, certain definite symptoms ensue. General fatigue, ill humor, cerebral exhaustion, sleepiness, bradycardia, itching and often disturbances in the senses of hearing and taste may often be directly traced to disordered hepatic metabolism.

The injection of comparatively large quantities of bile salts and bilirubin into the lower animals have been found to produce somewhat similar symptoms. It has been found that bile salts dissolve and break up the red blood cells and other body cells. Hemoglobin thus becomes diffused more or less into the blood, and as a further result following the setting free of toxic elements entering into cell constituents, intoxication follows.

Ordinarily and if unobstructed in its passage to the intestines, the bile becomes insoluble and is excreted. It has been demonstrated, however, that if all the bile could find an entrance into the circulation, the individual would be poisoned by his own bile in eight hours.

### TOXINS OF EXTERNAL ORIGIN—ALCOHOL, SYPHILIS, OPIUM.

In discussing the agents of external origin which are most frequently productive of nervous and mental disorders and which in their remote and direct effects are the etiologic factors causing the largest percentage of admissions to our asylums, space will only permit me to dwell briefly on three—alcohol, syphilis and opium. Other infections and drugs might be mentioned, and even coffee, tea and tobacco might be included in their share of censure in the production of neurasthenia and other nervous disorders, but undoubtedly these three head the list. I desire to include these agencies in my discussion, since many of the symptoms characteristic of alcoholism, syphilis of the nervous system and morphinomania, in both their acute and chronic stages, are due, not to the direct action of the external and primary poison itself acting on the nervous structures, but secondarily to an autointoxication resulting from a disturbed metabolism, the resulting products of katabolism being retained and reacting on the nervous and other structures.

### ALCOHOLIC AUTOTOXIS.

In order of importance as an etiologic factor, alcohol heads the list of external toxic agents influencing the nervous system detrimentally. The immoderate use of this beverage, prolonged over some months or years, will produce definite pathologic changes in neural and other tissues. An enumeration, however, of the most important morbid changes in organic structure, must convince one, whether the alcohol has been entirely removed or not, that a secondary self-intoxication is responsible for the peculiar mental and other symptoms which appear.

Among the most important pathologic findings are accumulation of fat cells in various organs, fatty degeneration of the heart, muscles, liver, kidneys and brain parenchyma, proliferation of connective tissue, cirrhosis of the liver, sclerosis and atheroma of the arteries and atrophy of certain organs. Nutrition becomes impaired, owing to vascular changes and disordered metabolism. Alcohol has a specific action on the neurons, shown by a disappearance of the chromatin granules and shrinkage of the entire cell. In the later stages the finer dendrites disappear entirely. The peripheral nerves are also acted on, neuritis and eventually localized paralyses resulting. To what extent these lesions are caused by the alcohol itself and by the poisonous products of katabolism, it is at present difficult to determine.

As a result of the alcoholic poison, indigestion, fermentation and dilatation of the stomach, etc., occur. Many of the symptoms of gastrointestinal autotoxis are present, even after a lengthy discontinuance of alcohol absorption. The furred tongue, heavy breath, loss of appetite, constipation, etc., are all indicative of the action of absorbed intestinal poisons.

Among the mental symptoms observable in subacute and chronic cases may be mentioned loss of memory and of self-control, incoherence of ideas and expression, irritability of temper, impairment of judgment, insomnia, headache, delusions and hallucinations, tremor, convulsions and general lassitude. Is it not probable that many of these symptoms may be due to autotoxic products being formed through the disordered metabolism resulting from the primary ingestion of alcohol?

In mania a potu the characteristic symptoms, such as restlessness and depression, insomnia, tremor, hallucinations, increase in temperature to 102 or 103 degrees, the frequent and feeble pulse, dry tongue and delirium may be more clearly assigned to autotoxemia as the productive agents than to any other factor.

### SYPHILITIC AUTOTOXIS.

There is no disease of mental or nervous character which presents symptoms referable to the action of toxic agents more conclusively than does syphilis. The primary stage is practically devoid of systemic manifestations, probably owing to the fact that the body cells are holding their own, so far as possible, in their fight against the invasion of the luetic virus. When the latter gains the upper hand, however, secondary symptoms set in, with the production of definite pathologic lesions, the third stage being a result of unobstructed degenerative changes to the organic and functional properties of the cells acted on.

The syphilitic virus seems to have a selective activity on nerve structure, comparable to the specific action of certain drugs on special organs and tissues. Nutritional and vasomotor disturbances complicate the mental aspect of the case.

The pathologic alterations are quite definite and easily demonstrated, such as gummatous deposits in the brain and cord, meningitis and arteritis, sclerosis, bone lesions, splenic enlargement, gummata of the liver and kidneys, etc.

It has been clearly demonstrated that after a variable length of time, the luetic poison becomes eliminated from the system, but not so with the autotoxic poison. Certain definite symptoms arise, such as mental dullness and irritation, melancholic alternating with maniacal stages, intense headache, loss of memory, of thought concentration, etc. Many of these symptoms can only be traced to the action of autotoxic bodies resulting from the katabolism following the action of the luetic virus, and reacting on the neural tissues, whether they were disturbed by the luetic poison or not.

### AUTOTOXIS IN MORPHINOMANIA.

The symptoms of chronic morphinism may be beyond doubt ascribed to an autotoxis primarily caused by the absorption of a poison in larger amounts than the body cells can readily take care of and excrete. No definite nor reliable pathologic tissue changes have been discovered to account for the characteristic mental symptoms, which seems to strengthen the idea that gastrointestinal autointoxication and retrograde tissue changes are to blame for the majority of symptoms.

Chronic opium ingestion will produce, as symptoms resulting from a depressant action on the nervous structure, indigestion, constipation, sluggishness of the liver, dizziness, sleeplessness, neuralgias and tremors, hallucinations of sight and hearing; both variable and fixed delusions are characteristic mental symptoms and are present during ingestion of the drug, as well as long after its discontinuance, before the various vital organs and functions have had sufficient time and opportunity to recover their normal organic structure and function.

The invariable presence of indigestion, constipation and liver torpidity, suggests the formation of autotoxic poisons, elaborated from these organs and acting as the direct, causative agents in the production and prolongation of the mental symptoms. In addition, a study of the blood shows a deficiency in the hemoglobin and red cells, together with an alteration in the form of the latter, which I have found to be crenated and granular.

As a result of this blood dyscrasia, the cells and tissues receive improper and insufficient nourishment, oxygenation is lessened and changed metabolism results, together with its varied manufacture of autotoxic poisons and resulting mental symptoms.

### CLOSING REMARKS.

It is the opinion of alienists in general that the proper and vigorous treatment of mental and nervous disorders in their incipiency would lessen to a great extent the number of admissions to our asylums. My experience in both asylum and private hospital work has confirmed my views that the rational treatment of many acute and subacute cases along the lines of deduction set forth in the preceding discussion will result in unexpected benefit and often remarkable recoveries. The confirmatory proofs accruing from treatment along the lines I have set forth will help to complete the chain of direct and circumstantial evidence that the conception of autointoxication when applied to many cases is no longer a mere theory, but a well-substantiated fact.

The precipitous onset of certain mental and nervous disorders may perhaps in some cases be made clear by a comparison to the symptoms of sudden poisoning following the administration of certain drugs, as for instance, digitalis. The clinical picture of digitalis action is usually slow in appearing and disappearing, and if administration of the drug is not carefully watched and guarded, acute symptoms of poisoning set in. This is due to the fact that the drug is slowly absorbed and as slowly excreted, so that incautious administration will precipitate signs of acute intoxication through the mass action of the latent drug.

The field is broad for further and more accurate work, and I wish my exposition of this subject to be considered only a step toward the solution of the many formidable problems still unsolved. The wonderful developments in biology during the past ten years, especially among the pathogenic bacteria, their toxins and antitoxins and their chemistry, method of formation and action, should stimulate us to still more earnest work.

I will endeavor to set forth in a future paper the lines of treatment I have followed in conducting the treatment of certain mental and nervous afflictions, exhibiting the various forms of autotoxemia elaborated in the preceding discussion.

# THE OCULAR COMPLICATIONS OF BRIGHT'S DISEASE.*

LOUIS STRICKER, M.D.

CINCINNATI.

### GENERAL STATEMENT.

The eyes become involved as a result of the general systemic conditions arising in Bright's disease. These systemic conditions, briefly considered, are the result of faulty kidney excretion, leading to the retention of urea or other excrementitious substances in the blood. These retained products are either poisonous in themselves or secondarily lead to the formation of toxins, thus producing inflammatory and degenerative changes in the vessel walls and the tissues of the body; or they may interfere with the proper conversion of the elements of food into those favorable for assimilation by the cells of the body, thus producing anemia and hydremia. To this abnormal condition of the blood is attributed the general arteriofibrosis, which finds its expression in hypertrophy of the heart and general increased arterial tension, leading to exudation and hemorrhage or total occlusion of the arterioles, with subsequent death of the parts cut off.

In the eye we find the vascular system (the choroidal and retinal vessels) and its nervous expansion (the optic nerve and retina) most frequently involved, although its media, the aqueous, lens and vitreous, may be secondarily affected. Paralysis of ocular muscles may follow as a result of cerebral involvement. All of the conditions are observed clinically, as hemorrhages, inflammations and degenerations.

The hemorrhages are due to the combined influence of arterial degenerations and increased arterial pressure. The inflammations and degenerations follow in the wake of improper nutrition and presence of toxins.

As a rule, as in all constitutional affections, ocular involvement is bilateral, but in some cases only one eye is primarily affected, and active treatment may so control vascular and nutritive conditions as to prevent the second eye from becoming affected. Ocular involvement is met with at all times of life, and may occur during the progress of acute Bright's disease, the Bright's disease of pregnancy, chronic parenchymatous and chronic interstitial nephritis. The majority of cases have been attributed to the last-named.

No doubt, many cases of Bright's disease develop ocular symptoms which are never discovered, as neither choroidal nor retinal disease causes pain, and unless the functional disturbances are prominent they are allowed to pass without further investigation. On the other hand, the oculist is not infrequently consulted for failing eyesight and makes the first diagnosis of Bright's disease.

In the acute forms, however, as a result of the rapid accumulation of toxic products in the blood, we find the nervous tissue of the eye more especially involved, and these cases are distinguished by the severe and diffuse character of the pathologic changes, from which the tissues may or may not be able to recuperate.

In the subacute forms it has been held that the changes are due to an interference with the nutrition in consequence of alterations in the vascular system. These vascular changes are attributed to toxic influences, but here likewise I believe that the toxins or other retained excrementitious substances play a more directly important rôle.

In these two forms of the disease we find either a diminished or normal quantity of urine and large quantities of albumin, and it has been inferred that the loss of albumin is responsible for improper nutrition. But this would not in any way explain the cases of chronic *interstitial nephritis*, in which the eye symptoms are said to occur most frequently, and in which we find large quantities of urine and only a trace or absence of albumin. So that in chronic Bright's disease we seek the cause of the ocular symptoms in the retention of excretory products in the fluids of the body which, acting as an irritant or a toxin, produce inflammatory and necrotic changes.

These excretory products, though constantly present in Bright's disease, in the beginning are not so in overwhelming quantities, and the tissues may be able to adjust themselves to changing conditions (a possible reason why all cases of Bright's disease do not develop retinal and choroidal changes), but in some a point is reached where the intoxication becomes excessive and the tissues react to the influence of irritants or poisons, and gradually succumb to permanent changes which are not easy to combat and offer a very unfavorable prognosis.

So that it seems rational to ascribe the ocular changes, especially choroidal and retinal, in all forms of Bright's disease to the same cause; namely, some constituent of the urine which is not excreted, but is retained in the blood, and acts as a chemical irritant or a toxin.

What the chemical nature of the products retained in the blood are, is as yet unsolved, but in all probability is connected with an improper elimination of urea. Since I have fixed my attention on this subject, I have found in a number of cases of Bright's disease, independent of the variety, a diminution of the urea quantity in the urine; that is, a retention of urea in the blood. In other words, the ocular symptoms are evidence of acute or chronic uremia. And we may place in the same category the cases of uremic amaurosis, in which the lesion or irritation is in the brain.

All text-books are vague on this subject. No attention is drawn to the fact that the seriousness of the case is not to be gauged by the loss of albumin but by the degree of auto-intoxication from retained excretory products, and that as yet we can do this only by a study of the percentage of urea in the urine.

So far as I know, no one has yet attempted to show that in all cases of choroidal and retinal disease accompanying Bright's disease there is less urea excreted, nor has a study of the relationship between diminution of urea quantity in the urine and the simultaneous increase of the severity, or even the presence of ocular symptoms, been made. We do know, however, that where the skin can be made to do the work of the kidneys vision does improve, though it be only for a time, since the control of eye symptoms depends on our success in controlling the kidney disease.

If this view that all cases of ocular involvement are due to chronic uremia and show a diminution of urea in the urine should be proved correct by observations in larger numbers of cases, it would also explain the reason for the comparatively rapid fatal outcome of nearly all, if not all, these cases.

The question would naturally suggest itself, how long a time after changes have taken place in an eye can a favorable outcome be expected? I should take it that vascular changes and exudates offer a better prognosis than changes in the nervous elements, the impairment of which, if degenerative, is permanent.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

The degenerative changes are usually so matted in exudates that when these are cleared away the results are often better than hoped for. Rods and cones cut off from their nutritive supply for three or four weeks can not be restored, nor will ganglion cells take on new life. A degenerated vitreous can not be restored, nor will lenticular changes and opacities be resorbed. So that the degree of vision ultimately to be retained depends entirely on the degree of insult to the globe before the patient comes under observation, the energy with which treatment is pushed, and, finally, the form of the disease, since better results may be expected from acute than chronic processes.

The ocular symptoms of the Bright's disease of pregnancy cause special concern. We are confronted here not only with the possibilities of a spontaneous abortion and the dangers to the mother incident to such an occurrence, but we are called on to decide whether it is justifiable to produce an abortion to save the eyesight of the mother, since it is well known that the kidney disease in such cases subsides quickly after labor is terminated. Ocular involvement in pregnancy indicates latent, but more serious possibilities, namely, puerperal convulsions, uremia and death.

In pregnancy, where albumin is found in the urine, the eyes should also be examined. The ocular lesions are but more delicate and sensitive reactions due to widespread intoxication, to which the whole nervous system is undoubtedly also subjected. An estimation of urea at this time becomes a matter of special importance, and where this falls below the normal the time for active interference has arrived. The estimate should be made with special attention to diet and quantity of fluid ingested for 24 hours.

Where the pathologic changes in the retina are not great, pregnancy far advanced and urea quantity nearly normal, one may temporize, but where widespread exudates and degenerative changes are taking place, urine loaded with albumin and urea quantity low, I believe labor should be induced not only to prevent permanent serious impairment of eyesight, but equally because the eye symptoms indicate the seriousness of the general condition and the possible fatal outcome of the case.

Whereas, in Bright's disease, both acute and of pregnancy, we may look forward to a certain degree of clearing up of the media and an absorption of exudates, so that we meet with partial, at times even complete, restoration of function, and the prognosis is favorable, in chronic forms the eye symptoms, as a rule, follow in the wake of nutritive disturbances of long standing, the degenerative changes are gradually induced and are premonitory symptoms of approaching dissolution. Various authorities place the time of life after retinitis sets in in the chronic form of Bright's disease at from three months to two years as the ultimate limit. I have seen death ensue within twenty-seven days after retinal degeneration was recognized. Only a small percentage of cases of Bright's disease (5 to 6 per cent.) develops ocular symptoms, but where this occurs it is always an ominous sign and a signal for active treatment.

The treatment of the ocular conditions of Bright's disease has for its object the furtherance not only of the elimination of toxic substances from the system and the general improvement of the nutritive conditions, but purposes a rapid interchange of fluids, so as to bring about a rapid resorption of noxious fluids and exudates in the eye. This is accomplished by stimulating or controlling the heart's action, by the drinking of large quantities of water, so as to flush the kidneys and dilute the poisons; to rid the system of the latter by active purgation, and, above all, by active diaphoresis, to cause the skin to do the work of the kidneys. Diaphoresis is of paramount importance. It is remarkable how quickly vision clears up on use of Turkish baths, where patients can get them, or by the use of a hot pack. (Pilocarpin injections are used, but are very depressing to the heart action.) The baths must be taken at least three times a week, and where the physical condition permits of it, every day. The hope of attaining good vision depends entirely on the rapidity with which we secure absorption of exudates, rid the system of poisonous substances retained, and on our success in improving the general nutrition.

### RESUME OF CASES.

Of 16 cases of the severer forms of the ocular complications of Bright's disease under my care 5 were cases of optic neuritis, 3 of neuroretinitis. 2 of neuroretinitis hemorrhagica, 2 of neuroretinitis and choroiditis, 1 venous thrombosis, 2 uremic amaurosis and 1 keratitis, in all probability a general uveitis. Seven cases had previously had medical treatment; only 5 were referred to me; so that in 11 cases attention was drawn by the ocular conditions to the true character of the disease.

Two cases occurring during the progress of pregnancy might fairly be considered as acute Bright's disease, and both are living. In one case vision has been greatly impaired, the woman having aborted in the seventh month. The other, a case of general uveitis, went to full term and was delivered of twins, and sight was fully restored.

Four were cases of chronic parenchymatous nephritis subsequent to la grippe, typhoid and measles. Three of these died, and there is no doubt in my mind that the fourth case died, though he passed from my observation. All of these cases showed more or less edema of their lower limbs, and two of them showed enormous hypertrophy of the heart, the whole left side fairly quivering with each pulsation.

All of them had a large percentage of albumin in the urine, and in two of them the urea quantity was found below the normal, and in one, though the urea quantity was not estimated, the patient had had uremic convulsions before I saw him.

Ten were cases of chronic interstitial nephritis. Two of these were in all probability of syphilitic origin; 1 was due to tubercular kidneys; 1 to general atheroma and senility; in 6 no cause could be assigned. Two of the latter (8 and 12) had no history of ever having been ill, while three had been treating for Bright's disease for periods of from 2 to 6 years. All had a greater or less degree of hypertrophy of the left ventricle, and showed traces of albumin; 1 case had had uremic convulsions, and 4 of the others showed a diminished urea quantity.

Seven of my cases died, the shortest period being, in one case, five days, in another twenty-seven days after coming under observation, the longest period being one year and three months. In 8 cases the urea quantity was below the normal; 2 had had uremic convulsions before I saw them.

Four cases passed from observation and the subsequent history is unknown, and 3 cases are living, the two cases complicating pregnancy and the one of retinal venous thrombosis.

Two cases had had apoplectic seizures previous to the development of the ocular symptoms.

Two cases have come under observation within the past month and are still living.

## CONCLUSIONS.

1. There are no ocular complications of Bright's disease from which, independently, a positive diagnosis of Bright's disease can be made. They should direct our attention to the probability of Bright's disease and lead to systemic examination.

2. The prevalent idea that one must find the characteristic picture of Bright's disease, with hemorrhages and areas of degeneration and white splashes in the region of the macula, is a mistaken one, since one may meet with any of the many manifestations of vascular or retinal inflammation due to the action of toxins.

3. Only a small percentage of cases of Bright's disease develops ocular complications, but if larger numbers of cases were systematically examined it is more than probable that a much larger percentage would be found to have ocular lesions, which have not caused functional disturbances, and consequently have been overlooked.

4. All the ocular complications of the disease are the result of altered nutrition, or toxemia; in other words, a chronic uremia.

5. Diseases of the eye coming on in the course of Bright's disease are of the most serious prognostic import, and indicate an early dissolution of the patient.

6. In the acute form conditions are of a more hopeful character, though a prolonged siege, with inability to stay ocular disease, can not fail to leave the patient, though he recover, with greatly impaired vision.

7. An estimation of the urea quantity made from a total amount of the urine of 24 hours, under proper diet, is the barometer by which we are to be guided in determining the early or immediate fatal outcome of the case.

8. In the Bright's disease of pregnancy, with ocular involvement, a low urea quantity should be a positive sign for immediate interference, and should justify artificial abortion both to save the eyesight as well as the life of the mother.

9. In cases of Bright's disease disclosing choroidal and retinal changes I have found the urea quantity in the urine below the normal; and it seems more than probable that the urea or other excrementitious substances retained in the blood, due to faulty kidney excretion acting as chemical irritants or toxins, are directly responsible for the inflammatory or degenerative changes.

## ILLUSTRATIVE CASES.*

### OPTIC NEURITIS, CHRONIC INTERSTITIAL NEPHRITIS.

Case 1.—Mrs. L. G., 57 years of age, came of her own accord, Dec. 22, 1902, owing to a sudden diminution in her vision. She has had two children; one died in its eighth year. The son is living and married. She has had some severe spells of illness; did not walk for six years, and states that she had peritonitis and has had an ischiorectal abscess. Is nervous and constipated, but has had few headaches. For the past two years her heart has troubled her considerably. A year and a half ago she had a stroke of paralysis of her entire right side, including an anesthesia of the right side of her face. Improvement began in the leg in a few days, but the arm and hand have never fully regained their strength. She had no aphasia at that time. From the time of her paralysis, she states that her vision was poor, and she found great difficulty in reading and sewing, but did not consult an oculist at that time. Her right eye, she says, has since that time been of little use to her, but the left eye has only been failing during the past week.

*Examination.*—She appears fairly well nourished, but says her weight has fallen in the past two years from 160 to 126 pounds. Her eyelids are markedly swollen, but no other signs of edema could be found in other portions of her body. The heart is enlarged; pulse strong and full, 100 per minute, and at times intermits and gets tumultuous. Heart extends one-half inch beyond the nipple line.

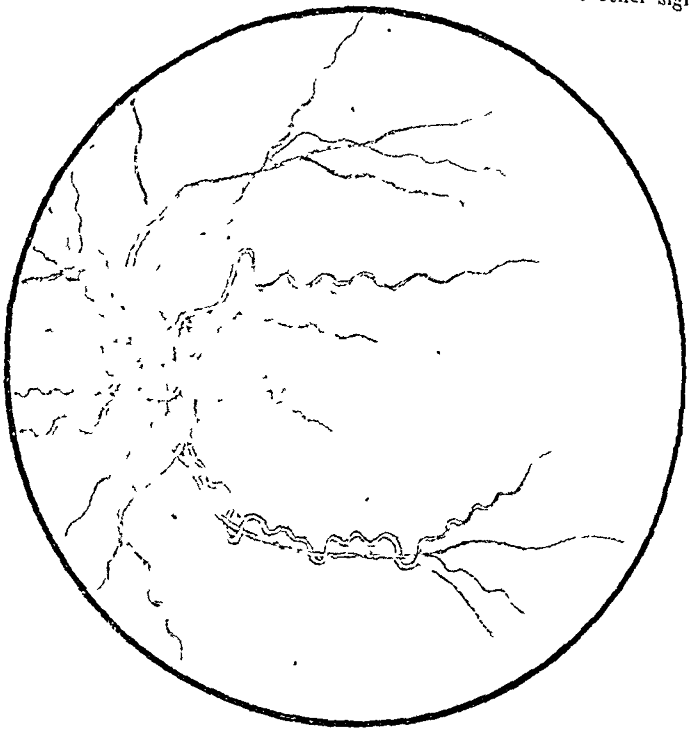

Fig 1.—Case 1. Optic neuritis, left eye

An examination of her fields of vision disclosed on the left eye loss of the entire nasal and lower segment of 150 degrees, and the remainder of the field is contracted down to 30 or 40 degrees, and this is extremely hazy, but in the retained segment colors are faintly recognized.

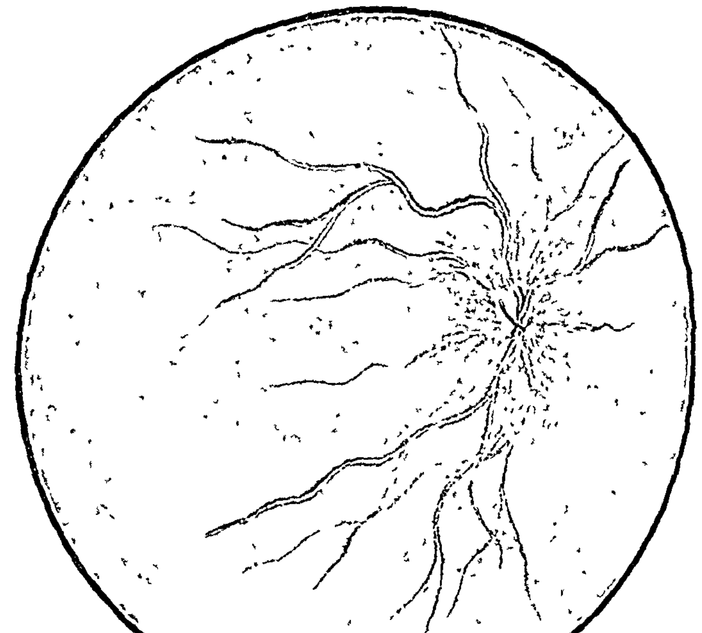

Fig. 2.—Case 2. Optic neuritis, right eye

On the right eye only the upper nasal quadrant, including the region of the macula, is retained, and this likewise is contracted. This loss of the nasal half of the left eye and the temporal half of the right eye would lead one to suspect a hemorrhage in the visual center on the left side at the time of her paralysis a year and a half ago, and this, I should take it, is entirely independent of her present illness, and this is partly borne out by the ophthalmoscopic examination, in which we find the left eye disclosing a pronounced neuritis, whereas, in the right eye, the disc is plainly visible and gives one more the impression of an optic atrophy. The consensual and direct reaction of the pupils is somewhat slow, though intact.

---

* The illustrations are the work of the author, made from sketches taken by the direct method.

*Ophthalmoscopic Examination, Left Eye.*—Vitreous slightly hazy, through which, however, the entire fundus is visible. The disc is markedly swollen and enlarged to double its size, and appears as a deep hyperemic area which is gradually lost in the retina. It has not the characteristic fire brand appearance, but very few enlarged capillaries being noticed on the surface. It has more the granular appearance. The arteries are normal in size, sharply outlined. The superior, however, can not be traced to their origin in the disc, but seem to emerge far out on the retina proper. The veins are double their normal size, extremely tortuous. A few striated hemorrhages are visible in the upper inner quadrant in the *hyperemic area, close to the disc*. Nowhere on the fundus can any signs of retinal degeneration or conglomeration of white exudates be observed.

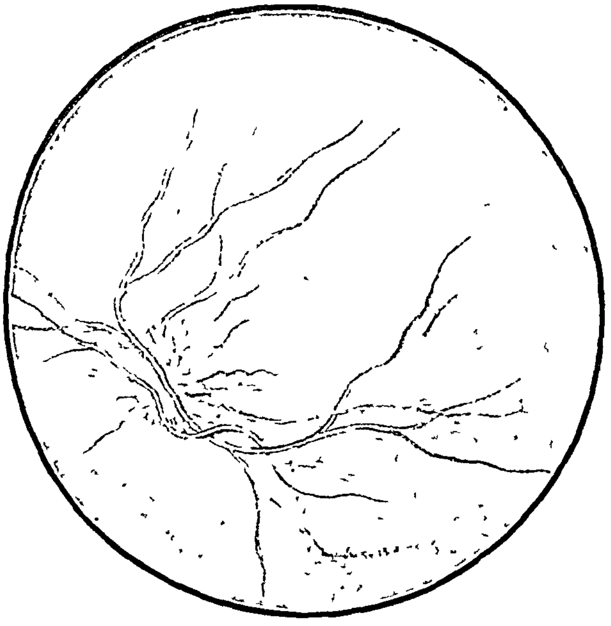

Fig. 3 —Case 2. Optic neuritis, left eye

*Right Eye.*—The fundus is veiled by vitreous opacities, but nevertheless the disc is distinctly visible and sharply outlined, with the suggestion of a bluish cast. There is just the slightest suggestion of beginning neuritis, notwithstanding the atrophy. The arteries are normal in size, whereas the veins are dilated, but show no tortuosities so markedly defined in the left eye. There is likewise here no suggestion of retinal degeneration.

*Examination of the Urine.*—Acid reaction, fair quantity of albumin; no sugar; urea quantity 0.35 normal. Passes enormous quantities of urine daily.

*Treatment.*—This patient was given bromid to quiet the heart, placed on a milk diet and given energetic sweat baths, and her vision in a few days commenced to clear up.

*Subsequent History.*—December 27. The hyperemia of the disc is not so great, inasmuch as on the left eye the vessels in the superior part can be followed now to their origin on the disc

Oct. 2, 1903. The patient is still living.

### OPTIC NEURITIS, CHRONIC PARENCHYMATOUS NEPHRITIS.

CASE 2.—S. S., 23 years of age, was referred to me for examination owing to some edema of his lower eyelids and for a very annoying scotoma scintillans. Suffered from typhoid fever in his fourteenth year, and was refused life insurance in his nineteenth year owing to albumin in his urine.

*Examination.*—He has a slight hypertrophy of the heart; apex beat a little below and to the left of the nipple line; pulse rapid and bounding.

*Examination of the Urine.*—Approximately three pints are passed per day, loaded with albumin; urea half of the normal quantity. Chronic parenchymatous nephritis.

*Ophthalmoscopic Examination, Left Eye.*—A distinct optic neuritis; the edges of the disc are faded, many dilated capillaries radiating from the disc, and a large area of edema follows the vessels for the lower half of the retina in their course. A white, edematous area occupies the region of the macula; vision =6/6.

*Right Eye.*—Vision =6/9. The disc is likewise edematous, swollen, great hyperemia of the vessels and a similar edematous area surrounds the vessels of the lower half of the disc.

*Subsequent History.*—This patient was not seen again until June 12, 1901. He tells me that he has had uremic convulsions; was in coma at one time for 36 hours. Ophthalmoscopic examination of both eyes showed large atrophic areas, many of them punctate in form, a result of violent choroidal inflammation. These areas are especially confined to the regions immediately surrounding the discs and in the macular region and for a distance along the line of great vessels, but they do not extend into the periphery. Owing to his great weakness, ophthalmoscopic drawings could not be made. He died Sept. 10, 1901—just one year and three months from the first time he visited my office.

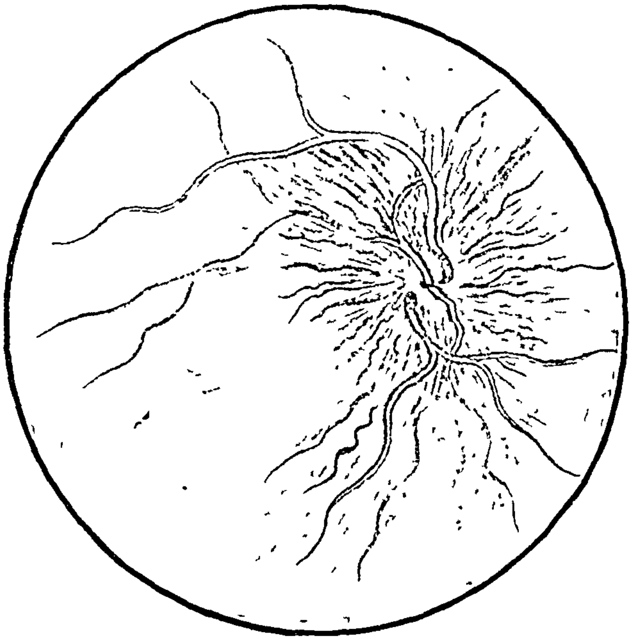

Fig. 4 —Case 3. Neuroretinitis, right eye.

### NEURORETINITIS, CHRONIC INTERSTITIAL NEPHRITIS.

CASE 3.—Mrs. B., a widow, aged 55 years, was referred to me October, 1896, for examination for glasses. She states that she has been under treatment for chronic Bright's disease for some time.

*Examination.*—Hypertrophy of the left ventricle, and an accentuated second sound. Patient is emaciated, weak and suffers from severe headaches, but has no edema

*Examination of the Urine.*—Large quantities of albumin. Diagnosis, chronic interstitial nephritis.

*Left Eye.*—Vision equals 6/60, with +150 D.; no improvement. Examination of the fundus shows the typical picture of retinitis Brightica. Papilla is enormously swollen, giving the typical fire brand appearance, +3 D. required to see it distinctly. All capillaries are widely dilated and tortuous, with many hemorrhagic *foci* scattered over the enlarged papilla. The veins are tortuous, overfilled, almost double their usual size, the arteries almost normal, but very tortuous.

In the region of the macula is a large atrophic area, surrounded by pigment, the result of choroidal atrophy. In the center of this area can be seen distinctly an exquisitely, sharply defined point, which reflects the light like a flame. Around this area of macular degeneration are many splashes of fatty degenerated retinal tissue. Also, the characteristic stippling on the region of the macula. *Following the course* of the vessels are also many splashes of retinal degeneration

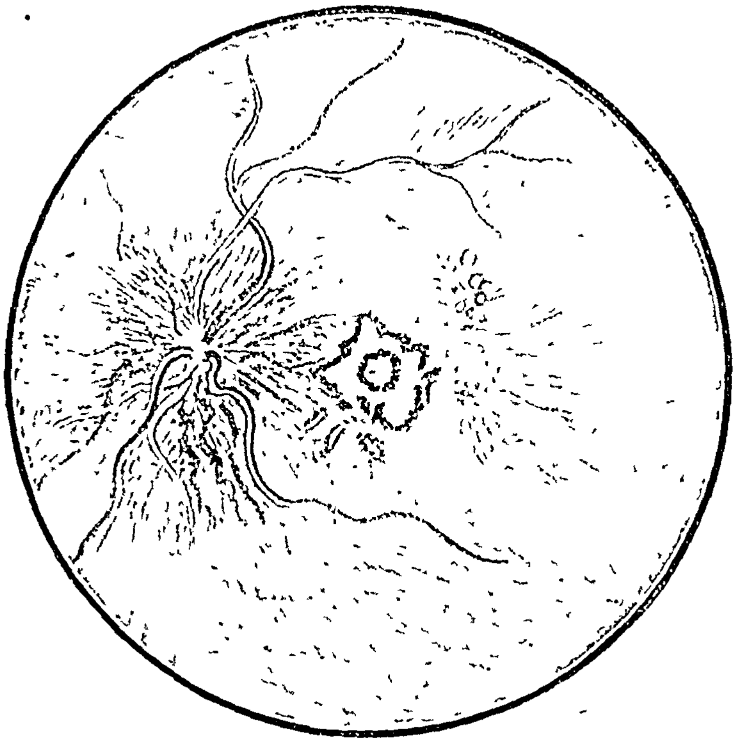

Fig. 5.—Case 3. Neuroretinitis, left eye.

*Right Eye.*—Much the same condition prevails—the hemorrhagic areas on the papilla, if anything, greater. The swollen papilla seems to extend far out into the retina proper. The region of the macula presents the characteristic figure, and here, likewise, areas of retinal degeneration follow the lines of the vessels. Above the macula are several hemorrhagic foci

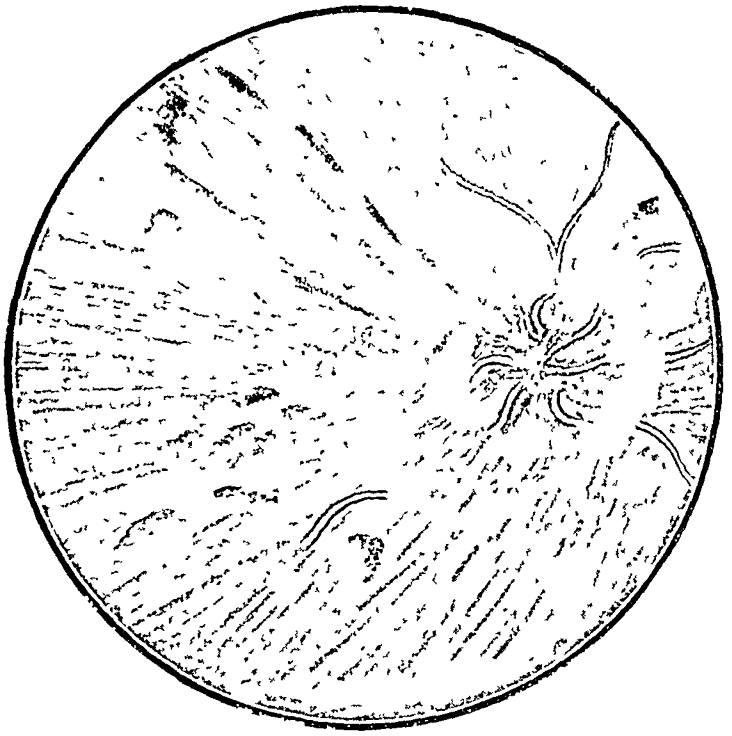

Fig. 6—Case 4 Neuroretinitis, right eye

*Subsequent History.*—No improvement was observed from treatment and the patient died in June, 1897.

### NEURORETINITIS, CHRONIC PARENCHYMATOUS NEPHRITIS.

Case 4.—William N., 33 years of age, was referred *to me* Sept. 10, 1901, for an examination of his eyes, which began to fail a week previously; he is a clothing cutter, married and has always led an abstemious life. He had typhoid fever a year previous to his present illness. He has had many dizzy spells, headaches and sickness of his stomach. He had a uremic attack a week previous to his visit, since which time his vision has begun to fail.

*Examination*—He has an enormously hypertrophied heart; pulse 120, full and tension high. His whole left side quivers with each pulsation. He has all the signs of arteriosclerosis on his temples

*Examination of Urine.*—He passes 7.5 pints of urine daily, which is loaded with albumin. Diagnosis, chronic parenchymatous nephritis.

*Present Treatment.*—Nitroglycerin to reduce violent heart action, and sweat baths by means of the hot-air apparatus; salts.

*Left Eye.*—Vision=6/60. The entire retina is so edematous that conditions in the temporal half can scarcely be observed. There is also some cloudiness in the vitreous, close to the retina, and considerable exudate behind the retina, so that the retina has a grayish appearance, with a possible slight detachment. In the region of the macula are some white glistening points and everywhere are white striated patches, more particularly in the upper half of the retina, where several large hemorrhagic exudates exist. The disc itself is so enormously swollen that the vessels can be only followed for a very short distance, and disappear in exudates, appearing again at long distance removed. There is enormous dilatation of all the capillaries of the disc and *hemorrhagic* areas scattered over the entire retina.

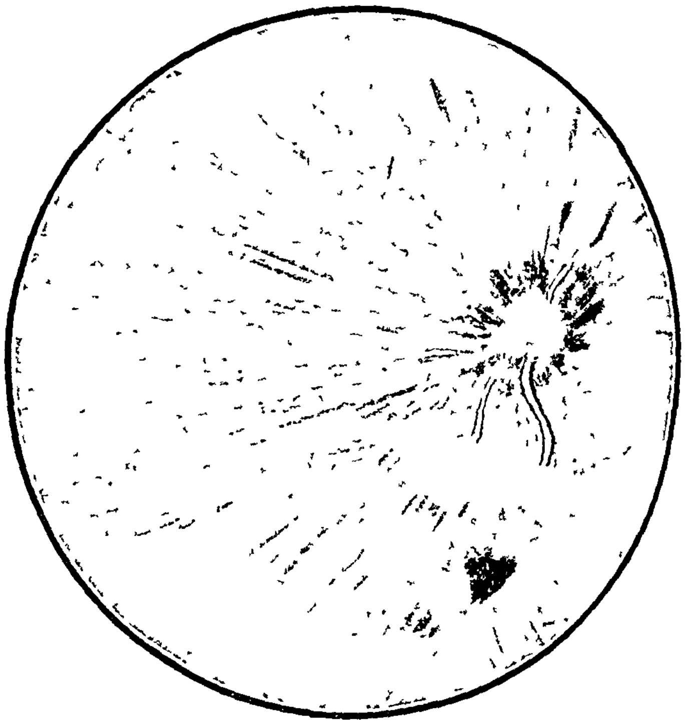

Fig 7—Case 4 Neuroretinitis, left eye

*Right Eye.*—Vision=4/60. The disc is edematous; enormously swollen; veins and arteries widely dilated and tortuous; disappear on the surface of the disc, and appear again at some distance from it. Many flaring hemorrhages exist over the entire fundus, and white areas of choroidal exudate, as well as degenerative and fatty changes in the retina, are marked everywhere The characteristic star figure in the region of the macula is present.

*Subsequent History.*—Ocular conditions were not materially improved by the general treatment, and the patient died Nov. 20, 1901, having suffered from general edema of the lungs, glossitis, neuralgia, and finally dying of an enormous hemorrhage of the stomach, possibly a uremic ulcer of the stomach

### NEURORETINITIS, CHRONIC INTERSTITIAL NEPHRITIS

Case 5.—April 5, 1902, I was called to examine the eyes of Mrs F. L, who had been under treatment for chronic interstitial nephritis for the past six years She had had repeated uremic attacks; was much emaciated and very weak. Her pulse was rapid and feeble; she was unable to read anything, and objects at a short distance were covered by a cloud.

*Ophthalmoscopic Examination, Left Eye.*—The vitreous was full of floating opacities, through which the disc is seen swollen, exceedingly hyperemic; its edges indistinct, and radiating from the disc in every direction are many flame-like hemorrhages. The disc is surrounded by many white patches, some of them flame like; others confluent, and in the region of the macula is a large white area, surrounded by many glistening points. The *right eye* presents practically the same conditions.

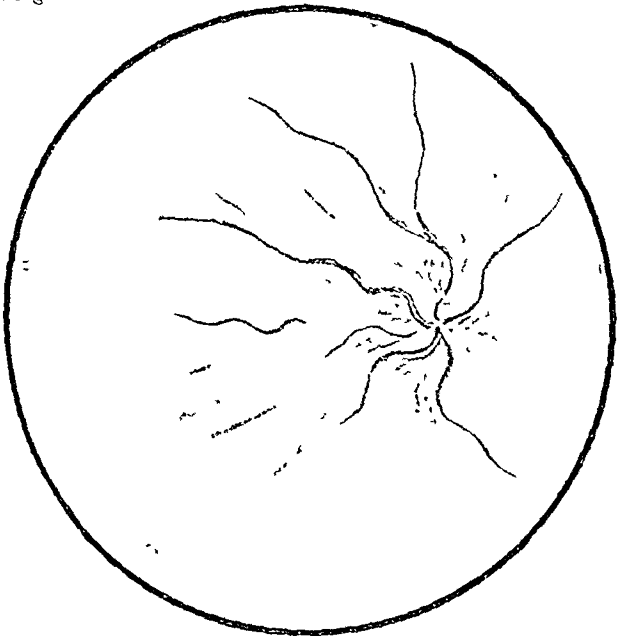

Fig 8.—Case 5. Neuroretinitis, right eye

*Treatment and Subsequent History.*—The patient was put through an energetic course of sweat baths, and vision seemed to improve, but death ensued June 21, 1902, the patient having been in uremic coma for four days.

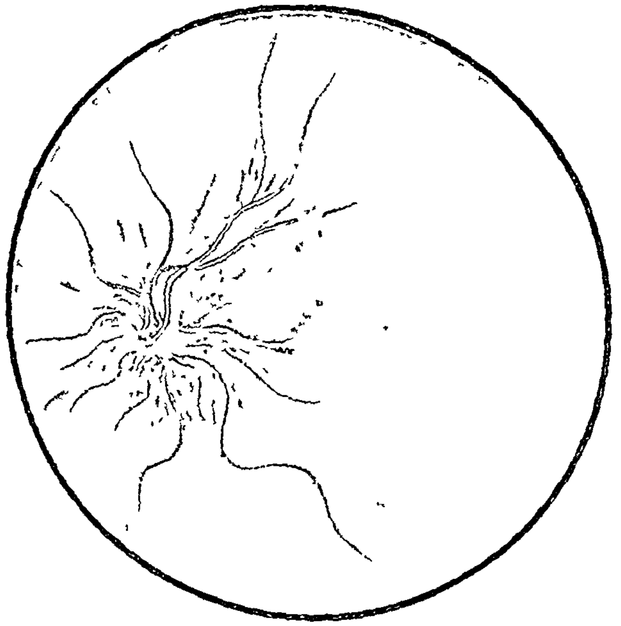

Fig 9.—Case 5 Neuroretinitis, left eye

NEURORETINITIS HEMORRHAGICA, CHRONIC INTERSTITIAL NEPHRITIS.

Case 6.—Mrs. O H., 64 years of age, came in March, 1902, to have her eyes examined for glasses, stating that her vision had been poor for the past four weeks; she is a large, stout woman, weighing 185 pounds, with no history of ever having been ill, except the occurrences of headaches and dizzy spells.

*Examination.*—The heart is enlarged, apex beat two inches beyond the nipple line, pulse 120, full and strong.

*Examination of the Urine.*—Sp. gr. 1008, much albumin, no sugar, no casts. Chronic interstitial nephritis.

*Ophthalmoscopic Examination, Left Eye.*—Vision is 2/60; can read no print. The disc is hyperemic; swollen; edges indistinct and hazy. Extending outward from the disc, taking in the area of the entire macular region, is a large hemorrhagic area, in some places so dense as to appear almost black. There is also an area of degeneration appearing white and glistening, exactly in the center of the macular region.

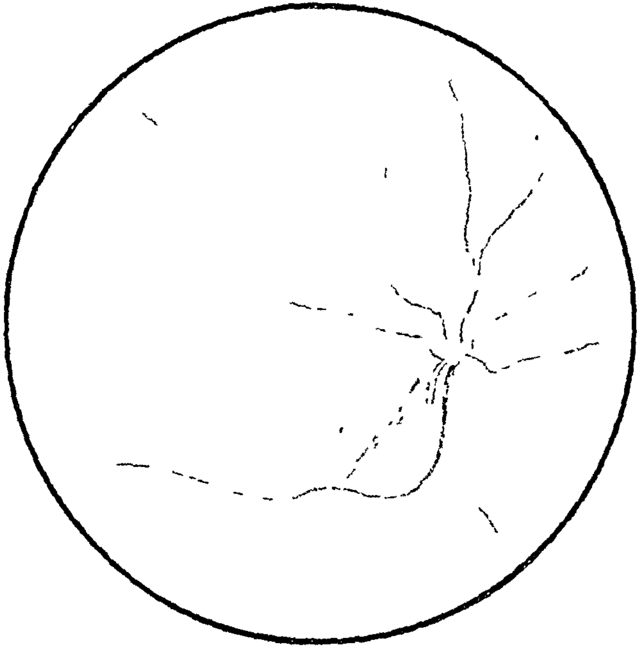

Fig. 10.—Case 6 Neuroretinitis hemorrhagica, right eye.

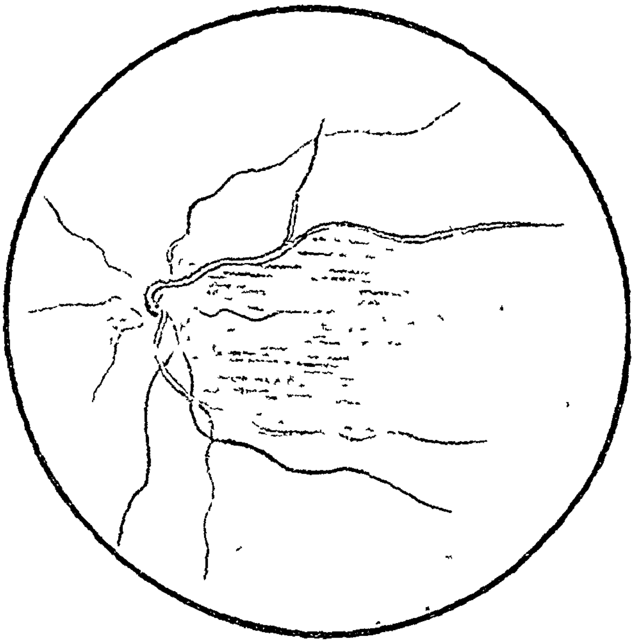

Fig 11.—Case 6 Neuroretinitis hemorrhagica, left eye

*Right Eye*—Vision equal to 6/36; disc is swollen; edges washed out, and extending downward and outward is a flame like area of dilated capillaries, in which the inferior temporal artery is lost The macula is not involved.

*Subsequent History.*—The seriousness of her condition was disclosed to her daughter, but they refused to believe my statements, and the case was lost sight of.

### NEURORETINITIS HEMORRHAGICA, CHRONIC PARENCHYMATOUS NEPHRITIS.

Case 7.—Miss E. F., aged 18 years, came of her own accord Aug. 22, 1899, owing to gradual diminution of vision. She states that two years previously she had the measles, subsequent to which she developed dropsy. Her father died of Bright's disease and two sisters died of tuberculosis. She has four sisters and two brothers living. She has had no other disease of childhood, but since having the measles she has never been well. At present she is very pale, anemic, listless; at times can not follow conversation; has constant pain in head, vomiting spells every day, especially on arising in the morning; her feet are swollen. She has never had a complete convulsion, though at times cramps occur in her hands and legs. She has had severe diarrhea at times.

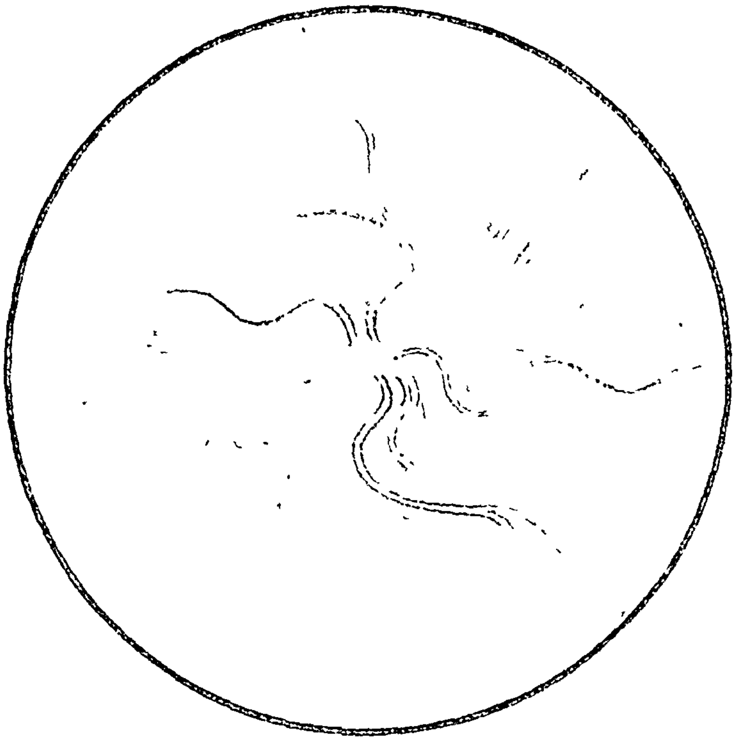

Fig 12.—Case 7. Neuroretinitis hemorrhagica, right eye.

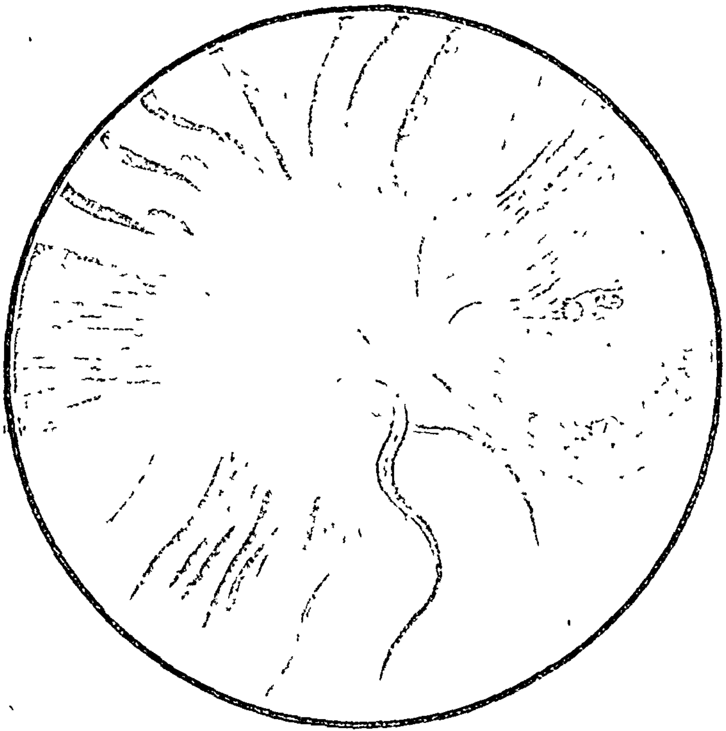

Fig. 13.—Case 7. Neuroretinitis hemorrhagica, left eye.

*Examination.*—Pulse rate is 128, full and strong. Her heart is enlarged beyond the nipple line and an accentuated second sound heard all over her left side.

*Examination of Urine.*—Her urine is loaded with albumin and the urea quantity is half normal. Diagnosis, chronic parenchymatous nephritis.

*Left Eye.*—Only light sense. Ophthalmoscopically the disc appears about three times its normal size, pure white, from which gradually radiate dilated capillaries. The veins are more than triple their normal size, the superior disappearing in exudates, the inferior, with great tortuosity, extending downward. The arteries are entirely lost in the exudate and swelling. The entire periphery of the retina is covered with radiating hemorrhagic areas, sometimes fine, sometimes in large blotches. The region of the macula displays a wonderful fatty degeneration, a formation of cholesterin crystals, extending downward, forming a large, almost triangular area.

*Right Eye.*—Vision =4/60. The papilla is more normal in size, but swollen. From its edges radiate dilated capillaries, which give the fire-brand appearance, and which are gradually lost on the surface of the retina. The arteries and veins are dilated and tortuous, and to the nasal side and upward are many fine radiating hemorrhagic areas, whereas, below are many confluent, white plaques. The region of the macula disclosed many white spots, and just above the macula is a large hemorrhagic exudate.

*Subsequent History.*—This young lady took to her bed the day I examined her, and died September 18, just 27 days after my examination.

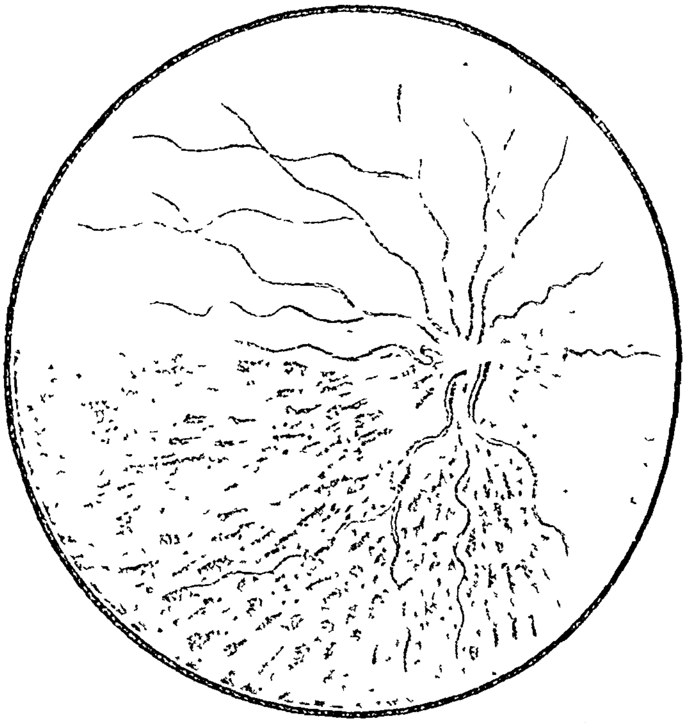

Fig. 14.—Case 8. Retinal venous thrombosis.

### RETINAL VENOUS THROMBOSIS, CHRONIC INTERSTITIAL NEPHRITIS.

Case 8.—Mr. E. B., aged 64, consulted me Jan. 31, 1898. He stated that on awakening from a sound sleep on the morning of January 30 he observed that vision of his right eye was completely blurred. He denies all venereal disease; in fact, he has no recollection of ever having had any disease.

*Examination.*—There was no external sign of disease. His pulse is strong and incompressible; heart enlarged.

*Examination of the Urine.*—Sp. gr. 1022; alkaline reaction, with but a trace of albumin; no casts.

*Ophthalmoscopic Examination.*—Vision of the right eye was but 6/24, and of the left eye a complete blur. The nasal and lower halves of the disc are indistinct and covered with fine hemorrhages. The two inferior veins are dilated to nearly four times their normal size, and following them downward in their course you find them strewn with hemorrhagic exudate; especially the inferior temporal vein shows two points at which the vein is entirely hidden by a grayish white mass, presumably the dilated portion of the vein, which I hold to contain thrombus. The veins in the lower half of the fundus are tortuous, and the entire lower half of the retina is strewn with hemorrhagic splashes. Curiously the entire upper half of the fundus, except a portion of the nasal, is free from hemorrhage; its veins and arteries are normal; whereas, in the lower half of the fundus, the arteries are much smaller.

*Subsequent History.*—This patient remained under observation for more than a year, but whereas the hemorrhagic exudate absorbed, his condition remained practically the same, and the upper half of the field was entirely wanting. He is still living.

[The discussion on the papers of Drs. Stricker and Suker will follow the paper of the latter next week.]

# THE DEVELOPMENT OF HARD TISSUE IN THE PULP OF HUMAN TEETH.*

DOUGLAS E. CAUSH, L.D.S.
BRIGHTON, ENGLAND.

Of the functions performed by the various organs of the body there are few, if any, more interesting or have the power of producing more varied results than that of the tooth pulp. In health it is the benefactor of the surrounding hard tissue; in disease, the medium whereby we are warned of the mischief that is going on. Among the varied functions of this organ may be placed the power of developing "secondary dentin."

Nature in many cases endeavors to overcome the evil produced by the destroying microbe, by forming a layer of fresh tissue between the soft, sensitive pulp and the dentin that is being broken down by decay; the same protective measure also occurs in those cases where erosion has commenced its destructive work, as well as in many other instances where disintegration of the hard tissue has been produced, by the various known causes. In all these examples the newly formed hard tissue is known as secondary dentin, the development of which we desire to consider in this paper.

On the examination of teeth, we find we may have new tissue more or less continuously developed from the pulp, until the tooth is lost either by disease or as a result of old age. In other cases the new tissue may be developed, without any apparent cause, and the development may be either continuous or spasmodic until the whole of the pulp chamber becomes filled with this new tissue. Again, we may find it in the pulp itself more or less surrounded by pulp tissue in the form of pulp nodules, and as Prof. Jos. Archovy has designated certain growths "Odontoma internum liberum."

In any and all of these cases the new tissue is spoken of as secondary dentin. It will thus be seen that there is a variety of tissue grouped under the head of secondary dentin, ranging from the comparatively structureless tissue as seen in the pulp nodule to that of the complicated character known as osteodentin. (Figs. 1 and 2.)

It may enable us to better understand the development of this tissue if we divided it into classes. We shall, therefore, consider first, normal secondary dentin; second, dentin of repair; third, pulp nodules, and lastly, a form of secondary dentin found in teeth where pyorrhea alveolaris has been pronounced.

## NORMAL SECONDARY DENTIN.

In the first class we shall include all tissue produced apparently without any cause, the whole of the pulp and surrounding tissue being healthy at the time of the deposition of the tissue. A good example of such may be frequently found in those teeth perfectly free from diseases, such as decay or erosion. Nor have the teeth been worn down by attrition; yet on examination they are found to have their pulp chambers partially or entirely filled with new tissue. This tissue may be very varied in its microscopic appearance, from that of an almost structureless character to the more complicated containing lacunæ-like spaces, and frequently an innumerable number of tubuli. The tissue is usually found in the twelve anterior teeth, but perhaps more frequently in the lower incisors and canines. There is, as a rule, no inconvenience produced by its development, and its presence is only detected on examining the tooth after extraction.

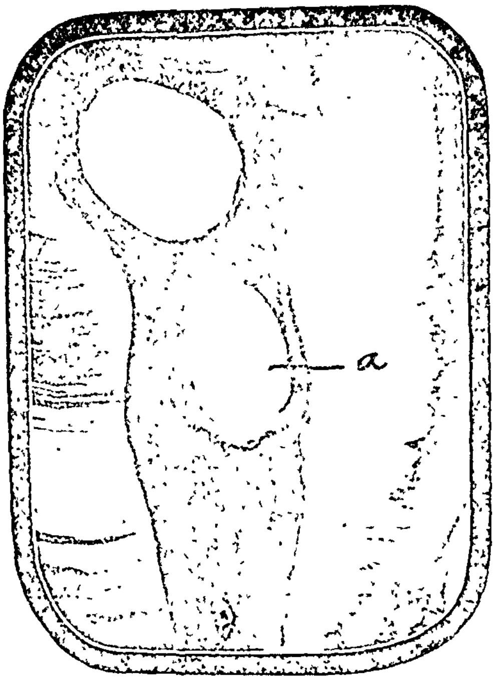

Fig. 1.—A pulp nodule, showing structureless character of secondary dentin.

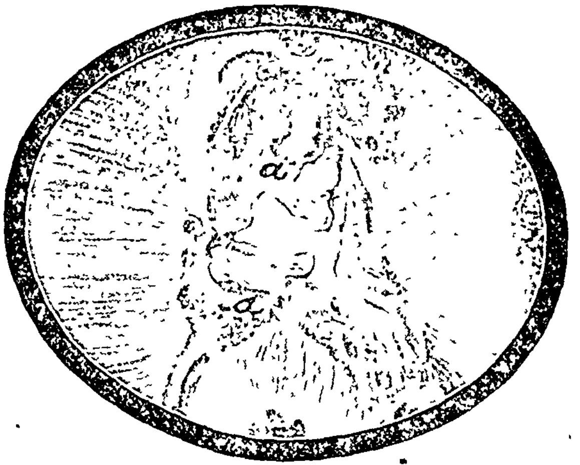

Fig. 2.—a. Osteodentin.

It would appear to be Nature's way of reducing the size of the pulp chamber, and is much more pronounced in those who have passed middle age. It is rarely found in pulp canals; the deposition commences usually at or near the apex of the pulp chamber, gradually working downward toward the point where the chamber is united to the pulp canal. Even when the tubuli are in large numbers they rarely assimilate with those tubuli previously formed; hence it is not at all difficult to define the line of demarcation between the two tissues. This line is usually very pronounced, owing to the fact that some time has elapsed between the calcification of the old tissue and the commencement of the deposition of the new, and as a consequence the first layer laid down usually appears structureless and often followed by a number of irregular spaces very similar in character to the intergranular layer of the dentin, and then if the deposition is continued, tubuli are regularly formed. If, on the other hand, from any cause the deposition is interrupted we have a mass of mixed tissue—structureless, lacunæ-like spaces, and tubuli, all mixed together. The development of this tissue is as follows: After the dentin has become perfectly calcified in a healthy tooth fresh formative material is brought to the pulp by the blood; this passing to the outer layer of the pulp by capillaries is taken up by the layer of globular or semi-globular cells (Fig. 3) surrounding the odontoblasts, and these cells become eventually calcified. As this calcification takes place the odontoblasts are restricted in size by compression and the odontoblast cells forced inward toward the center of the pulp, the constricted portion forming the tubuli. If the deposition is slow, the outer mass becomes very solid, and as a consequence structureless with few tubuli. If, on the other hand, it is rapid, some of the cells do not calcify and lacunæ-like spaces are thus formed with their canaliculi produced as minute spaces between the calcified cells. As this process goes on new cells are formed by cell division. If during the process of calcification any dense tissue is met, such as the walls of the blood-vessels (arteries or veins), the cells surround this dense tissue, and calcifying around them form the circular openings so frequently seen in the sections of this tissue, often carrying by pressure the odontoblasts with them, and thus tubuli are seen surrounding the openings. If, on the other hand, no dense substance is met, the calcification goes on continuously until the whole of the pulp chamber is filled with new tissue, thus producing the variations found in this tissue.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

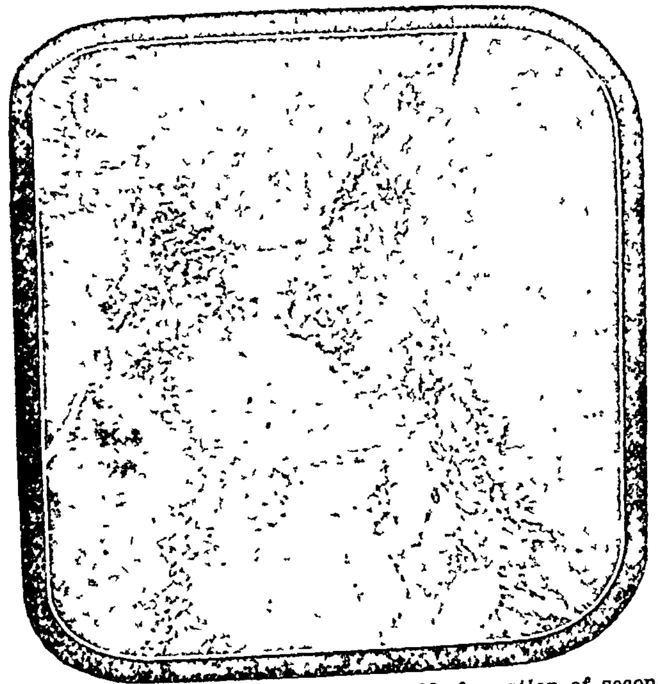

Fig. 3.—Pulp chamber superior bicuspid, formation of secondary dentin.

The cause of all this may be and probably is, the slight irritation—so slight that the patient is unconscious of it—produced in the pulp by the constant use of the teeth.

### DENTIN OF REPAIR.

The second class, and by far the most numerous, spoken of as dentin of repair, may be divided as follows: 1. That found in teeth with eroded surfaces. 2. That found in teeth that are decayed. 3. That found in teeth worn down by attrition and mastication. The pulp nodule is produced from quite a different cause—irritation produced in the pulp itself.

On the microscopic examination of the teeth placed in section 1—teeth with eroded surfaces—we have found in every tooth examined that there has been a deposition of secondary dentin. This new tissue assimilates that of normal dentin more than in those of the other sections; the line of demarcation is more pronounced following the area of the eroded surface. It is much more clearly defined and certainly more restricted in its development, having, as a rule, tubuli assimilating with the tubuli of the dentin, and apparently there is little or no break in their continuity. At the same time there appears to have been a marked change in the condition of the tubuli of the original dentin. Immediately under the eroded surface we find the tubuli of the original dentin very difficult, if not impossible, to stain. It appears as if these tubuli had been filled with some deposit from the outer surface of the tooth that prevents them from performing their usual functions. The function of the secondary dentin is to prevent any acute irritation passing from the eroded surface to the pulp itself. Owing to the restricted area of its development it would appear as if the deposition was caused by the slight local irritation produced in the earlier stages of the disease of erosion.

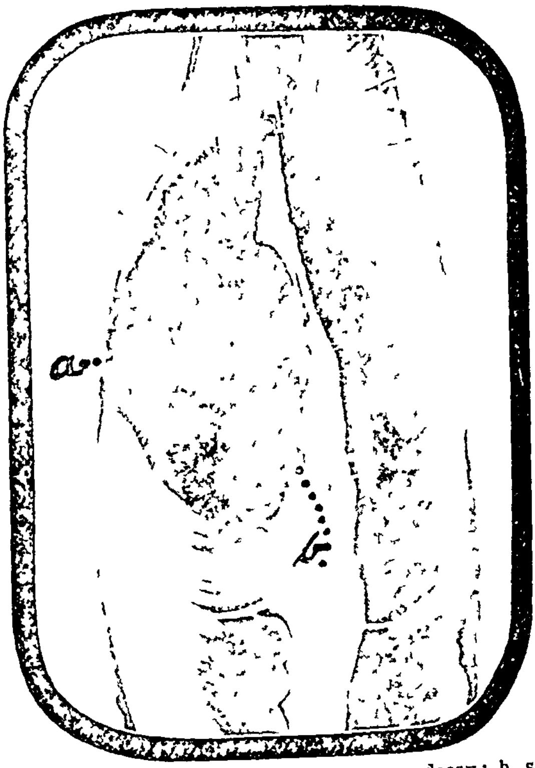

Fig. 4.—Secondary dentin under decay: a, decay; b, secondary dentin.

The development of secondary dentin in the second section is, as far as my examination goes, much more rare, and is found only in those cases where the decay has gone on slowly (Fig. 4) and the irritation to the pulp tissue has been as a consequence slight and continuous, but extending over a long period, differing from the former in microscopic structure. It varies very much in structure as well as in the area of its deposition. The earlier deposited tissue does not, as a rule, contain any tubuli, but a number of lacunæ with canaliculi. As the tissue increases in thickness it assumes more the character of normal dentin and a number of tubuli are developed. It usually spreads over a much larger area than that of the secondary dentin in eroded teeth, and does not terminate in such a pronounced or irregular manner. It would lead one to suppose that the irritation to the pulp tissue had been much more general. It is still an attempt by Nature to protect the pulp from the results of the diseased condition of the tooth, produced by the action of the spreading of the decay.

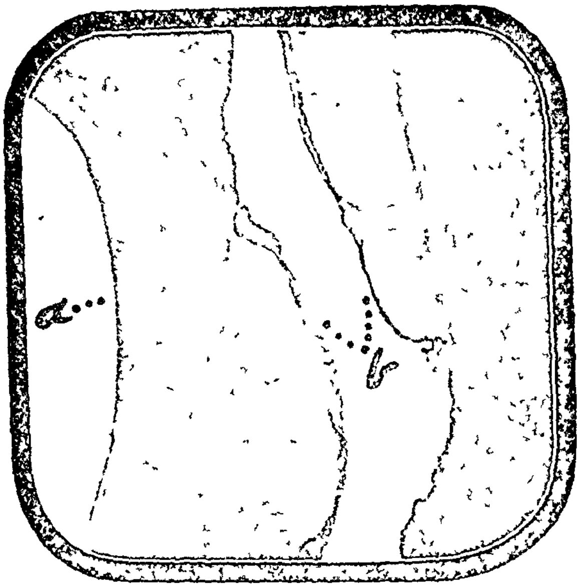

Fig 5 —Section of superior canine worn away at the sides by a metal band on artificial tooth plate; though the tooth is worn away by attrition, the deposition assimilates that found in eroded teeth a, Portion of tooth worn away by band, b, deposition of secondary dentin

In the form of secondary dentin placed in the third division, that produced by attrition or mastication, we have the teeth worn down oftentimes in extreme cases until the original pulp chamber has become exposed. The teeth usually affected by the attrition are the six front ones of both upper and lower jaw (Fig. 5)—those worn down by mastication, the bicuspids and molars. In either case the result is the same. The tissue is usually quite structureless at the commencement of the deposition, passing from that through either of the other forms until we have a mass of dense tissue all fused together and entirely filling the pulp chamber; so dense, that in extreme cases, even if the original pulp chamber has been exposed, there is little or no discomfort to the patient. This tissue is more like the tissue previously referred to as normal secondary dentin than that of any of the others. In all these cases the method of development has been the same, and the cause, that of irritation in one form or another; but in all cases the exciting cause has been from the outside, i e, from that portion of the tooth above the gum line.

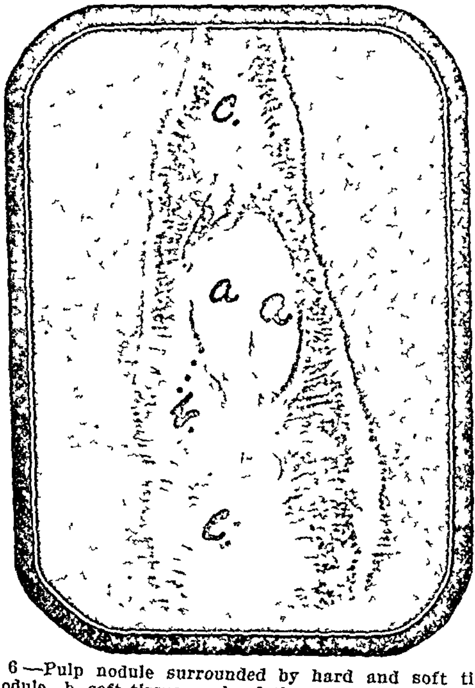

Fig. 6 —Pulp nodule surrounded by hard and soft tissue. a, Pulp nodule, b, soft tissue, c, hard tissue For nodule surrounded by soft tissue see Figure 1

### DEVELOPMENT OF THE PULP NODULE.

In this case we have a pronounced deposit of secondary dentin, either in the pulp chamber or the pulp canals, sometimes in both: but unlike the deposit in the previous sections, the nodule is always formed as a result of irritation in the pulp itself.

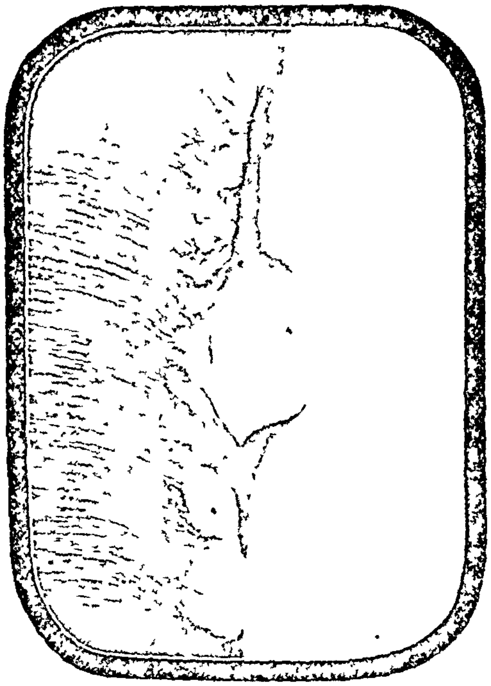

Fig 7.—Pulp nodule attached to original dentin with tubuli curved around nodule

On examining a tooth there is nothing in the external appearance to suggest the existence of even the smallest of pulp stones, nor can we take into consideration as a factor the age or sex of patients in the development of this tissue, as these nodules are to be found in the teeth of patients in their teens as well as in those of advanced age, and in many cases producing as much pain in the youngest as in those of old age. The result of my examinations tend to show that the position of the nodule is usually the cause of the pain produced.

In external appearance the nodules vary from a small more or less globular or oval structure to that of any size or shape, controlled only by the size of that portion of the canal or chamber in which they are found. Thus we have them from a minute point to those entirely filling the pulp chamber, and in teeth of two or more roots it is not unusual to find them not only filling the pulp chamber, but with spines of hard tissue passing into the various canals, and thus producing the most irregularly shaped nodules.

Their position is almost as varied as their outline, for, as I have already said, we may find them in the pulp canals and pulp chambers, quite free from the surrounding dentin, or we may find them attached to the sides of the pulp canals and quite surrounded by the dentin. (Figs. 6 and 7.) It is not the largest of these that cause the greatest amount of pain, as the pain is produced by the position and not by the size of the nodule. Thus a small nodule near the apex of the canal will probably produce pain by the constriction of the pulp (Fig. 8), and as a consequence pressure on the nerves, while a nodule much larger in size (unless there is pressure produced on the nerves) may almost entirely fill the pulp chamber without producing any discomfort. Though their size, shape and position may vary very much, such is not the case with regard to their microscopic structure. (Fig. 9.) All the nodules I have examined have a somewhat similar structure when viewed by the microscope. We have usually in the center or somewhere near the center of the developed tissue, a space more or less pronounced, and it is at this point that the nodule has its origin. (Fig. 10.) It grows outwardly, and radiating from this point there are usually a number of more or less concentric rings caused by additional layers of calcified tissue. It is in this way a nodule increases in size. This may continue until two or more nodules touch each other and become united into one, thus forming a compound nodule large and irregular in shape. Its structure, as thus seen, is quite different from either ordinary or secondary dentin. We may sometimes find a few isolated, irregular tubuli, but rarely do we find any tubuli approaching the character of those seen in secondary dentin. This may be accounted for by the fact that its origin is generally some distance from the odontoblastic layer, and the nodule is developed from a different layer of cells from that of secondary dentin. Its position would imply that no odontoblasts had taken part in its development, and if this is so, a very interesting question arises as to how these tubuli, if they are tubuli, are produced.

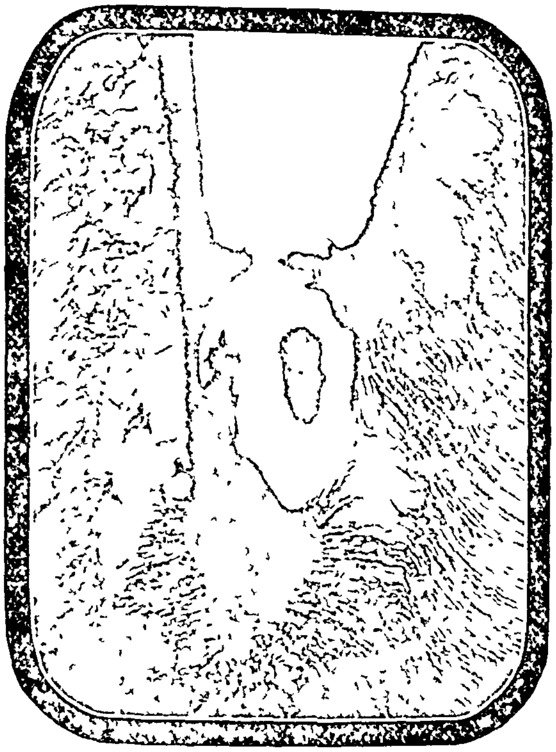

Fig. 8.—Nodule at apex of root canal, in this position causes great pain. The dense tissue almost surrounding nodule is pulp.

The origin of the development of the nodule is some irritation in the pulp itself, and I believe the primary object of the nodule is to cover up, by calcification, some substance that has been the cause of irritation in the pulp tissue. Its structure, as well as its mode of development, would lend itself to this supposition, for under the microscope we have a structure similar in appearance and I believe identical in its mode of development to that of the pearl found in the oyster, the origin of the pearl being a foreign body in the mantle of the mollusc. As it is impossible for the oyster to get rid of this foreign body by absorption, it builds around the cause of irritation that which is known to us as the pearl. So in the development of the pulp nodule the same has occurred. Nature has found in that delicate and complicated structure—the pulp—something it can not get rid of, something it can not absorb. The irritation produced by this something causes the pulp to endeavor to get rid of it; as, however, it can not absorb it, there is nothing for it to do but to encyst it.

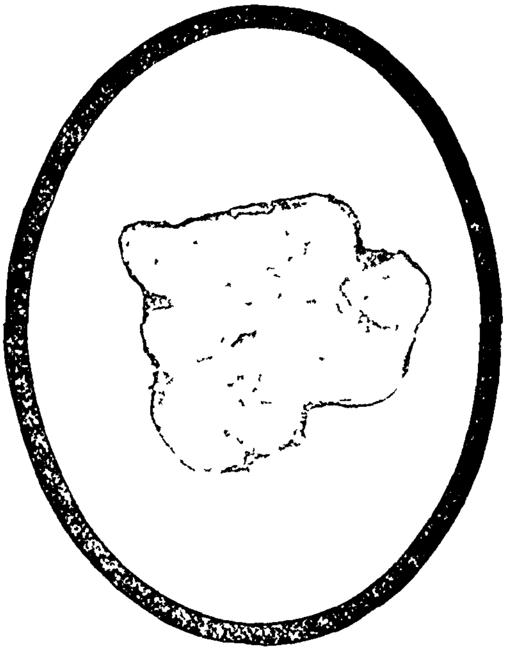

Fig. 9.—Section of pulp nodule taken from pulp chamber of superior molar.

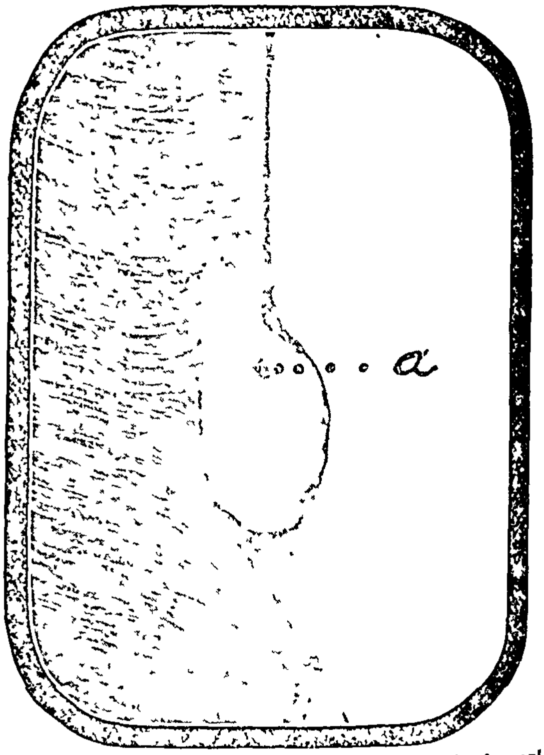

Fig. 10.—Pulp nodule showing what I believe to be origin of nodule at a.

If this is the true origin of the pulp nodule, we ought to be able to find in some pulps, as a result of microscopic examination, the exciting cause, and this exciting cause is, I believe, to be found in either a dead cell or cells, or perhaps, a few blood corpuscles that have by some means escaped from their ordinary course, either by the rupture of one of the capillaries or small blood vessels abounding in the pulp. Such an accident may occur by a sudden shock to the tooth, or, again, the corpuscles may be found out of their place as a result of the breaking down of some of the smaller arteries, veins or even the capillaries by disease, such as the pulp is exposed to.

I think the former method is the one that usually causes the development of the pulp nodules in our younger patients, while undoubtedly the changes in the pulp lend themselves to the development of these nodules as age advances. We will suppose from either of the above, or some similar cause, that such a change has taken place in the pulp, and as a result there will be irritation of a more or less pronounced character in this tissue produced by what has become a foreign body.

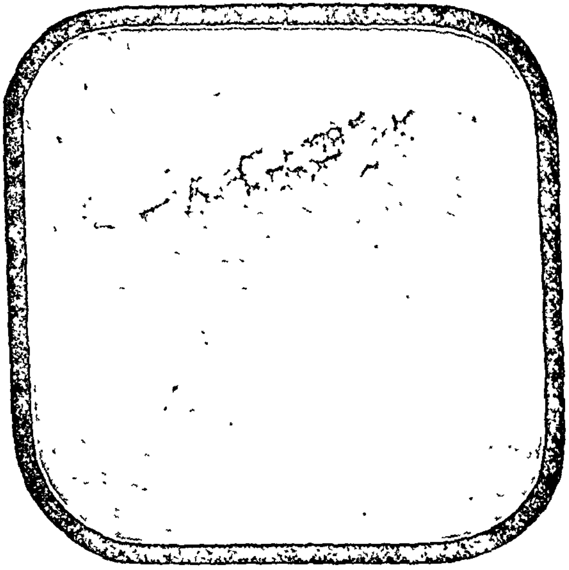

Fig. 11.—Interglobular spaces in dentin as seen in teeth affected by pyorrhea alveolaris. Note the globular character of the dentin.

There are no lymphatics for the reabsorption of this body; it does not require a very great stretch of the imagination to trace the growth of the pulp nodule on the lines laid down. The course followed would, I believe, be somewhat as follows: The irritation produced by the foreign body causes an increased activity in the blood vessels surrounding the cause of the irritation, and, as a necessary consequence, an increase of formative material brought to hand. This material is taken out of the blood by the surrounding cells, and it becomes a very simple matter for these cells to cover up the cause of the irritation by a deposition of hard tissue. This probably occurs as follows: The increased blood supply produced by the irritation causes immediate activity in the cells surrounding the cause of irritation, and the result of the activity is to produce a number of new cells. The pressure produced by this increase in the number of cells again increases the blood supply, and after a time the cells deposit a hard tissue in the same manner as the cementum is produced in exostosis.

As the deposition takes place in very small quantities, and probably very slowly, we have a more or less perfectly calcified and, as a consequence, homogeneous deposition. This accounts for the structureless character of the nodule.

Again, we sometimes have a larger mass more rapidly formed, and perhaps nearer or even including some of the odontoblasts in the newly forming mass. We shall then have variations in the structure, consisting of lacunæ with canaliculi, irregular spaces and a few markings like the tubuli of dentin. As the calcification of these cells continues, we shall have an increase in the size of the nodule. In some cases this increase causes a further irritation of the surrounding pulp tissue, and thus a constant supply of fresh formative material is brought to the cells. The increase of size eventually produces pressure on the nerves of the pulp and, as a consequence, frequently the most acute pain is experienced. This is the course, I believe, of the pulp nodule when surrounded by pulp tissue.

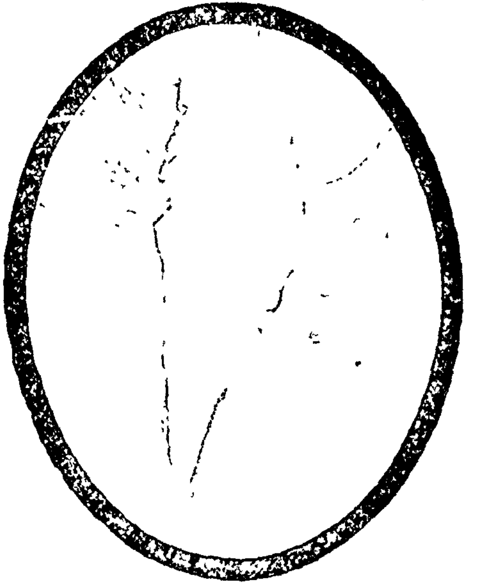

Fig. 12.—Absorption of dentin in teeth having pyorrhea alveolaris.

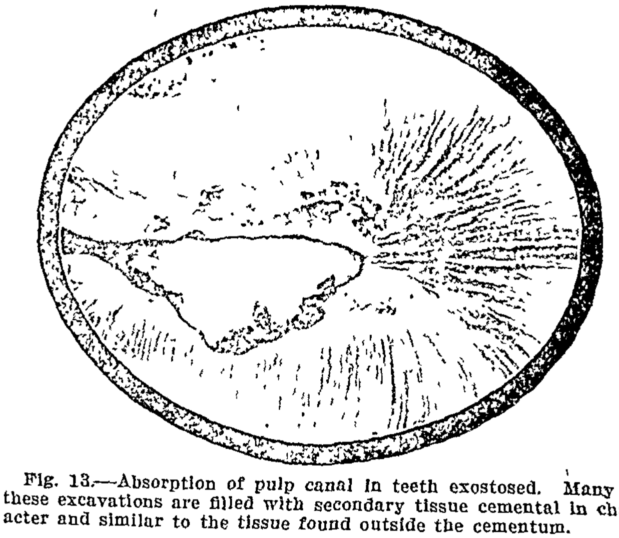

Fig. 13.—Absorption of pulp canal in teeth exostosed. Many of these excavations are filled with secondary tissue cemental in character and similar to the tissue found outside the cementum.

There is yet another class of nodule; though previously mentioned, it may be interesting to briefly follow its history. I refer to those nodules attached to the dentin. We may also, if we are fairly successful in our search, find them not only attached at one side, but entirely surrounded by dentin, and that at some little distance from the pulp canal. Wherever I have found these they have always been near the apex of the root and embedded in the last-formed dentin; and this, I think, gives the key to the explanation of the position in which the nodules are found.

At the time the cutting edge of the tooth is passing through the gums, the apex of the root is in an uncalcified condition, and with a new tooth in this position it is much more subject to a shock than it will be after it is fully erupted. As a consequence, we have a nodule formed in precisely the same manner as those formed in the pulp tissue, with this exception—those found in the pulp tissue are always formed after the calcification of the dentin has taken place, while the latter class are formed prior to the calcification of the tooth, and when first formed are surrounded by uncalcified dentin. Any careful examination of a tooth with nodules in this position will fully illustrate my meaning, as the tubuli of the dentin will be found to be bent around the nodule, proving the nodule must have been formed prior to the calcification of the dentin. If it had been otherwise and the dentin had been absorbed to make a space for the nodule, we should then have found the tubuli ending abruptly at or near the margin of the nodule, but this is not the case. (See Figs. 7 and 10.)

This will also account for the nodules found in the pulp canals but attached to the dentin, and here, I believe the development has been the same as in nodules surrounded by dentin.

### DENTIN ASSOCIATED WITH PYORRHEA ALVEOLARIS.

The last of the forms of secondary dentin we wish to draw your attention to is to be found in the pulp chambers and pulp canals of teeth having been removed owing to the pronounced action of pyorrhea alveolaris. In all the teeth examined (about 100) the original dentin has been of very poor structure, containing a large number of interglobular spaces (Fig. 11); the dentin generally badly calcified and more or less absorption of the cementum and sometimes the dentin at the apex of the root. (Fig. 12.) In the pulp itself the first thing that attracts our attention is the absorption of a portion of the original dentin forming the pulp chamber and canal, probably the result of acute inflammation prior to the development of the secondary dentin. The new tissue is very varied in character, and apparently consists of a mixture of tissue similar in structure to that found in the previous cases, with the addition of a very large amount of isolated globular secondary dentin wherever there is a piece of pulp tissue; so that the whole of the pulp chamber canals are more or less filled with either secondary dentin as previously described, or an innumerable number of these globular bodies, generally isolated, but sometimes, though very rarely, found fused together. I have noticed similar excavations in the pulp canals of teeth that are exostosed, but with this difference: the cavities in the latter case are frequently filled with secondary tissue like the additional layer or the outside of cemental tissue. (Fig. 13.) In the case of pyorrhea alveolaris, the excavations are not filled with any special tissue.

All the microscopic slides used for illustrating this paper are hard sections ground down, as I believe decalcification in any form is liable to alter the conditions of the tissue under examination.

## DISCUSSION

### ON THE PAPERS OF DRS. CONSTANT, MORGANSTERN, CAUSH AND RÖMER.*

Dr. Eugene S. Talbot, Chicago—Just where the dental papilla leaves off and the dental pulp begins is a question worthy of discussion. What is called the dental papillæ still requires a large amount of research, especially along the line of histology. It was for the purpose of bringing this organ more forcibly to the notice of the profession that I had instituted these symposiums from year to year in our proceedings, and I trust that more work will be done on the histology, physiology and pathology of this structure. The pathology in erupting teeth is clear. No matter what the propelling force may be, there is an irritation set up around the crown of the tooth in the alveolar process. This irritation produces inflammation. Halisteresis and Volkmann's perforating canal absorption are set up and room is made in the bone for the advancing crown. The same inflammation, although not quite as severe, sets the bone cells at work, at the border around the root, thus forcing the tooth forward. It is barely possible that these bone deposits are what Pierce intended to illustrate by pounding on the barrel to remove the bung. If Mr. Constant is correct in his theory, so far as the starting of the crown is concerned, I may agree, but certainly it would not account for the eruption of the tooth after the roots had begun to form. The blood space is so small and the resistance so great, that it would appeal to me to be due rather to the bone cells filling around the roots than to blood pressure. What is true of the eruption of teeth also holds good in teeth that have lost their antagonism years after the roots are completely formed. In regard to root absorption, I do not understand the difference between pathologic and physiologic absorption of roots or bone tissue. Absorption is absorption, regardless of the irritation and inflammation. The only difference I can see is one of degree and form. The death of the pulp *per se* does not make the root incapable of absorption, as suggested by Mr. Constant, nor does the crown impinging on the dead root always cause the deflection.

There are three forms of bone absorption—osteoclast or lacunæ, halistersis, and Volkmann's perforating canal absorption. All are brought about by irritation and inflammation. Root absorption is always due to osteoclast or lacunæ absorption. It makes no difference whether the pulp of the tooth is alive or dead, this absorption is the same. If the pulp is dead, the absorption is much greater than when alive, as witnessed in implanted teeth. When the pulp of a temporary tooth is destroyed or dies, irritation is set up at the end of the root, inflammation of the peridental membrane and alveolar process takes place, and the surrounding bone and trabeculæ or fibrous tissue which hold the lime salts together are destroyed. Since it is necessary for the trabeculæ or fibrous portion of the alveolar process to be present in order to hold the osteoclasts, it being destroyed, the osteoclasts can not absorb the roots of the temporary teeth. The remark of Sudduth that the absorbed and the absorber must be in close connection is very apt in this case. The alveolar process having been destroyed, the root of the temporary tooth is only held in position at the cervical margin by the gum and alveolar process. The deflection of the root, therefore, may be simply the result of mastication, and not always caused by the crown of the permanent tooth.

We are obligated to Mr. Constant not only for his paper, but his presence at this meeting, and while we are not so many in number, yet I can assure him that the theories advanced in his paper will ever after be associated with his name in relation to this subject in this country. The purely scientific men in this country or abroad are few, but there is this satisfaction to him as well as to us, that we are trying to advance our specialty along given lines regardless of nationality.

---

* The paper of Dr. Constant appeared in The Journal January 16; that of Dr. Morganstern, January 23; that of Dr. Römer, February 6.

DR. M. H. FLETCHER, Cincinnati—I would like to ask Mr. Constant why the tooth is not pushed forward after the root is completed.

MR. T. E. CONSTANT, Scarborough, England—Dr. Fletcher and Dr. Talbot apparently are at a great difference on the same point. Dr. Talbot says that he agrees that the tooth could commence erupting, but does not believe that after it is formed there would be force enough to keep it coming up. That is what I pointed out. In the illustration there is a broad base of vascular tissue on which the tooth rests; consequently, the lifting force is very great. There is a little extrusive force in the peridental membrane, as occurs when there is inflammation of the pericementum, when the tooth is raised in the socket. The reason the tooth is not entirely extruded is that while the pulp is alive the alveolus accompanies it to a certain extent and by the time the alveolus has gone a little beyond the normal level the fibrous tissue in the pericementum has developed to such an extent that it forms a ligament for the tooth, and this development of the fibrous portion of peridental membrane ties the tooth in its socket. I did not explain that in the paper, because I believed it would go without saying.

DR. M. H. FLETCHER, Cincinnati—If I understand the condition that Mr. Constant describes, it seems to me that the subject, for the purpose of discussion, might be divided into the physical properties and the chemotactic or the opposite of the physical. His hydrodynamic theory of the pressure from below, by the pumping of the blood, seems to me the most satisfactory explanation we have heard—if we must have a physical explanation for the process of eruption of the teeth. It is not clear to me, however, that we need such a theory. To take another view of the subject, we will consider movements which can hardly be classed as mechanical or physical, which, from my point of view, should be considered in this connection. The peristaltic motion of the intestines is an example of the extrusion of effete bodies; this is muscular and consequently mechanical, but the extrusion of foreign bodies or pus from the flesh is not mechanical in the same sense, but is more like the eruption of a tooth. The expulsion of the ovum from the ovary, however, is seemingly a force of a different type, and I do not see that we could class it with either hydrodynamics or mechanics; again, when the ovum is about to be expelled, the fimbriæ of the fallopian tube reach out and embrace the ovary. We can easily understand how, when the ovum is discharged into the fallopian tube, it may be forced along by the ciliated epithelium. But why do we have the rising to the surface of the ovum? What is it that causes the fimbriæ of the fallopian tube to grasp the ovary? We have here powers in physiology which, to my mind, explain more fully the mechanism or the processes of the eruption of the teeth than any mechanical explanation. To cite other processes which should be weighed in this connection, consider the attraction for each other, of the male and female elements in fertilization. After fertilization then comes segmentation of the ovum. What is it which causes this proliferation of cells and the differentiation into epiblast, mesoblast and hyoblast? Here are forces which seem to me can explain the process in question. Why do we have the development of two or three roots in the molar teeth and single roots in the incisors? This differentiation of structure in the development of tissue, I believe, is yet unexplained, but it must be accepted just as we accept the production of electricity by dynamos, the law of gravity and many phenomena of the universe which as yet we do not comprehend. The unexplained chemotactic attraction or repulsion of organic bodies or cells, in the study of karyokinesis, is a most striking example of an unknown force which I believe must be the one involved in the eruption of the teeth; in other words, I believe the movements in this process must be looked for in the study of cytology rather than in mechanics. The kinetic energy which divides the nuclei of cells and drives the separated parts into opposite ends of the cell, resulting in the mother and daughter elements, is a force which must be taken into account. The multiplicity of this force, created from the myriads of developing cells found in embryonic and growing tissue, certainly would create an energy much greater than is required for the eruption of the teeth. I should be pleased if the theory of Mr. Constant could be accepted as final in this problem, but to me his mechanical plan is not the most scientific way of working it out, although I believe it may be one step toward the solution. If we can determine that this is really the process or even a part of the process, we are nearing the solution, not only of this problem, but of many others within the domain of biology.

DR. HANS PILCHER, Vienna—I believe, with Dr. Fletcher, that we do not know all about the evolution of the teeth. We do not know the cause that starts the whole thing. We do not know the cause that starts the first labor pains, the first movement toward the birth of the child. I believe we know now the mechanical forces which bring about the movement in the tooth. The theory of Mr. Constant seems so extremely natural to me that I believe in it to its fullest extent. In some way the process can not be entirely mechanical. If there is not something that induces an increased pressure in the pulp tissue there would be a similar pressure from the other parts, even though they may consist of hard bone. I believe that the vasomotor nerves or the trophic nerves must have their influence in this particular kind of movement. I would like to ask whether any one has observed in a case of acute inflammation of the peridental membrane that a tooth did not elongate because the roots had not the conical form. I do not believe there is such a case, with the exception of cases in which there is very great divergence which would make a mechanical impossibility of the tooth coming out. It seems to me that those teeth in almost all cases elongate, so I believe the increase of blood supply in the peridental membrane may be taken as an explanation of the final coming out of the tooth.

DR. A. E. BALDWIN, Chicago—I believe there is no law of dynamics or of science whereby we can fully explain these so-called physiologic laws. The explanation mentioned by Dr. Fletcher of the discharge of the ovum is not fully accepted, although it seems to be the most plausible explanation extant. I have long since dismissed as unworthy of consideration the theories advanced regarding the eruption of the teeth and that advanced by Mr. Constant seems to me the nearest approach to a solution.

DR. M. L. RHEIN, New York—It affords me the greatest pride and satisfaction to have been the chairman of this section at a time when this paper has been presented to us. Dr. Pilcher brought up a very interesting question bearing on this forcing up of the tooth and whether it was more common in conical roots than in teeth with roots turned and twisted. In comparative anatomy, we all realize how the conical tooth of the rodent will ultimately cause the death of the animal if the occluding tooth is lost, showing continuation of this force at work. Of course, the tooth does not have the periosteal ligamentous attachment that we find in the human tooth. In the same way in clinical work on the anterior teeth, especially the superior incisor, one of the most distressing forms of peridental disease is the sudden commencement of elongation of one of the incisor teeth, carrying with it the additional formation of the pericementum of the root itself. There are two points about this pathologic condition that appear to me to strongly confirm the ideas presented to us. The first is the fact that the shape of the roots of these teeth is very conical, and there is nothing in their shape that in itself would prevent such a forcing out of the tooth. The view presented by Dr. Pilcher, and in conjunction with this a number of radiographs that I have taken of such teeth have shown little nodular deposits on the pericemental tissues at different points of the root surface. The connection between these nodular deposits and the forcing out of the tooth has never been clear to me until I listened to Mr. Constant's paper. It seems almost conclusive to me that this has interfered with the retentive force of the ligamentous tissue that holds the roots in the position they should occupy when they have been properly erupted. The second reason is that I have failed to see one case of this kind in which this process of elongation has not stopped as soon as the pulps of these teeth have been removed; and, in a number of these cases, I have found in sealing of the ends of the roots, orifices that were larger than those often found in an ordinary tooth. These are some of the instances that keep coming back to me in thinking of the practicable adaptability of these views, and the more I have thought of them the more have I been impressed that Mr. Constant's theory is the most scientific interpretation of the physiologic action of eruption of all heretofore presented. I feel that this section has been highly honored in being the vehicle of presenting this paper to the scientific world.

Mr. Constant—First, I thank you for your very kind remarks and the kind manner in which you have received the theory that I have placed before you. It would be impossible in the short time at my disposal to enter fully into every fact with regard to the eruption of the tooth. All that I desired to point out was that the very simplest fact in the *whole problem* had been ignored. It was not my intention to enumerate the things we did not know. When we say that we do not know why the ovum comes to the surface of the ovary, I think that there certainly must be something other than the mere mechanical force in connection with the eruption of the teeth. I think they are reasons we all fully recognize, but I do not think they are reasons for putting forward the purely mechanical side and ignoring the other. Dr. Talbot stated that he did not think there was any difference in the removal of roots of temporary teeth by resorption and by absorption. On that point I disagree.

Dr. Talbot—I said in roots that had dead pulps and implanted teeth. [Dr. Talbot here reread the statement referred to.]

Mr. Constant—I inferred from that that Dr. Talbot was of the opinion that whether a temporary tooth was alive or dead, exactly the same process of absorption occurred, but I see that it does not admit of that construction. My contention is that it is rather more than a question of degree. The appearances, so far as I have seen them, seem extremely different in the two instances. In the one case you get very sharply clear-cut nodules of the edge of the root. In the case of the root of a temporary tooth in which the pulp is being destroyed (I am speaking now entirely of the macroscopic appearance) the surface of the dead root is covered with thick membrane and the edges of the absorbed part are smooth. That is what I term the result of pathologic process of absorption. The physiologic process of resorption which takes place when the pulp is alive differs very markedly, that difference being the sharp margins and the absence of one thickened membrane, which has the greasy feel in the other case. Dr. Talbot speaks of the process of the removal of subadjacent tissue from the advancing crown as a process of inflammation. I do not like the term, inflammation, used in that connection. I do not want to enter into the point of exactly what takes place during the removal of subadjacent tissue, as I wish the simpler point to be cleared up first. Until we are in agreement as to the mechanical force which brings the tooth to the surface we can make no progress. Until we can determine the process by which the tooth comes up it is idle to discuss more complex questions. The point I wished to bring before you, and which I have succeeded in making clear, is that mechanical part of the process which is the simplest and it is the part that has been ignored. That there is a mechanical force there can be *no doubt in the mind of any* dentist who has seen a tooth pressing on the gum before eruption. It has been urged that the tooth came up simply because the subadjacent tissues are removed; but that idea would be dismissed after close observation. In regard to a corroborative point, I ventured in the paper to touch on pathologic conditions, and I can assure you that since I have worked out this theory, some years ago, I have found no pathologic condition that has caused the slightest doubt in my mind as to the applicability of the theory. The point that the chairman mentioned and which would strongly confirm the view is, that in the case of a six-year molar, in which the pulp has been prematurely destroyed, one finds afterward that that tooth does not come up properly into line as do teeth in which the pulps have not been destroyed, and when it does it is not accompanied by any corresponding growth of the alveolaris; that is to say, there is slight extrusion, but not sufficient extrusion to bring it into occlusion with the opposing tooth.

Dr. M. L. Rhein—A point in corroboration of the fact that removal of the tissue is not sufficient to aid in the eruption of the teeth, is the occurrence that we have all seen so often, the premature lancing of deciduous teeth and the reformation of scar tissue, even though the lancing is done in the most thorough manner. I simply mention this as a corroborative point and one which is conclusively clear.

# SPLENIC ANEMIA;

## REPORT AND DEMONSTRATION OF A CASE.*

M. J. LICHTY, M.D.

Lecturer on Medicine and Physical Diagnosis in the Cleveland College of Physicians and Surgeons; Visiting Physician to the Cleveland General Hospital; Visiting Physician to the Cleveland City Hospital.

CLEVELAND, OHIO.

Mrs. S., aged 32, who was referred to me last fall through the kindness of Dr. Rosenwasser, gives the following history: The family history, including that of uncles and aunts and grandparents, is negative. She was born and reared in this city; has never lived in a malarial district; has had no venereal disease and was a healthy girl, never having had any serious illness. She was married at 26, and has two healthy children. She has never had any miscarriages. In March, 1900, more than three years ago, she noticed that she was losing weight and strength, and that her feet and ankles were swollen. The abdomen also increased in size, and both the feet and abdomen were tender to touch. The menses became irregular, appearing at intervals of six weeks, or three and sometimes even five months. These symptoms continued more or less uniformly for more than two years, though the abdomen seemed to increase in size constantly, so that she presented the appearance of a pregnant woman. She also soon noticed a large hard mass in her left side beneath the ribs. For two years also she was attacked with frequent attacks of severe bleeding from the nose. In July, 1902, one year ago, she was suddenly seized with a severe and serious gastric hemorrhage. She thought she vomited more than three pints of blood. Blood was also noticed in the stools for several days after. The hemorrhage, she said, caused more weakness and exhaustion than she had noticed at any time since the beginning of her sickness, and convalescence to her former condition was very tedious.

In September, 1902, she called on Dr. Rosenwasser, who referred her to me for an examination of her blood, as well as any other examination which I should care to make. The mass which she had noticed in her left side could easily be felt without complete removal of her clothes. It was in the splenic region, had the shape of the spleen, moved with respiration, was not very tender to touch and was supposed to be the spleen. The thought of a nice case of splenic leukemia at once presented itself. To my surprise, however, the blood was entirely different from that found in the usual case of leukemia. The hemoglobin was 50 per cent., the number of red blood corpuscles was 4,288,000, and of white corpuscles 4,000—a leucopenia instead of a leucocytosis. A differential count of white blood corpuscles showed nothing abnormal in the proportion of lymphocytes and polymorphonuclears found in health. Only a few eosinophiles were found, a few nucleated red corpuscles, no megaloblasts, and there was no poikilocytosis. The corpuscles were uniform in size.

The enlarged spleen, hemorrhages and the blood with a marked anemia, low color index and leucopenia, were the three important physical signs pointing toward the diagnosis of splenic anemia. Other physical signs noticed then and since are as follows: There is poor nutrition, pallor, no icterus and no cyanosis. The face shows considerable pigmentation, so that she does not appear anemic. The reflexes are normal and there is no glandular enlargement. The feet, ankles and legs as far as the knees are much swollen, though there is no pitting on pressure. The chest is small and the intercostal spaces are sunken. The abdomen measured 31 inches in circumference. The lungs were apparently normal. The physical signs of the heart were very interesting. The base of the heart is in the second intercostal space to the left and the apex in the fourth. The chest wall is so very thin that one can hardly say whether there is a palpable thrill or not over the heart. The heart is perhaps slightly enlarged, unless the thin chest wall only makes it appear so. In the second and third intercostal spaces to the left there is a loud systolic murmur not transmitted much beyond the area of the heart. It does not disappear nor seem to be modified much by change of position. At some of the subsequent examinations the murmur was much less distinct. I am unable to come to any satisfactory conclusion as to whether this is a hemic or organic murmur. (The same kind of a murmur has been found in several cases which I have collected, though in only one, that reported by Hawkins, was any lesion found at autopsy. In his case there was a stenosis of both mitral and aortic valves.) The liver extended from the fourth intercostal space to three-finger breadths below the costal border. It was smooth with a round edge and not painful. The spleen extended from the sixth intercostal space in the left axillary line and the eighth in the back, to the crest of the ilium and almost as far forward as the median line. A notch could easily be felt, if not seen, in the anterior border. The spleen also is smooth with round edges, not painful to touch, and is rather firm. The kidneys are not palpable. The lesser curvature of the stomach is about two finger breadths above the umbilicus and the greater curvature three or four below the umbilicus. The abdomen was very prominent and there seemed to be some free fluid in it. The urine was highly colored, acid, contained a trace of albumin, but no casts.

---

* Read before the Cleveland Academy of Medicine.

Dr. Rosenwasser prescribed Fowler's solution in increasing doses, and she seemed to improve at once. In November he referred the case to me for treatment. She was then feeling very much improved, though the physical signs were about the same as six weeks before, except that there was perhaps more anemia, hemoglobin 53 per cent., erythrocytes 3,252,000, and leucocytes 3,500. The ascites was also more marked, the abdomen being 34 inches in circumference, and there was much more albumin in the urine with some casts. The swelling of the feet, however, was disappearing. It seemed that the albumin increased in quantity as the dose of the Fowler's solution was increased. When the ascites was most marked there was a scant, highly albuminous urine, and there was much diarrhea. In February the arsenic was discontinued. In March there was only a trace of albumin and no casts. Instead of arsenic she has been taking three times daily two drams of glycerinated extract of red-bone marrow. This has seemed to agree with her, and though the blood examinations are not so very much better, if any, she at the same time feels much better. For the diarrhea and ascites there were given three times daily five grains each of diuretin and salicylate of bismuth. She was also given a very scant diet of bread, butter and milk only. Under this regimen she improved rapidly, the diarrhea and ascites having disappeared in less than a month when the abdomen was again 31 inches in circumference. In spite of her limited diet she has gained in strength. In April the menses appeared, the first time since November, 1902, lasting one week, nothing abnormal. She has menstruated again in May and June. She has not been confined to her bed since the hemorrhage of nearly a year ago. She calls at my office for treatment, does her own house work, has a good appetite, sleeps well, walks considerably, is not dyspneic, and is one of the most cheerful and hopeful patients to be found. Blood examinations during the last nine months are as follows:

| | Hemoglobin, Per Cent. | Red Blood Corpuscles. | Leucocytes. |
|---|---|---|---|
| Sept. 27, 1902.......... | 50 | 4,288,000 | 4,000 |
| Nov. 15, 1902.......... | 53 | 3,252,000 | 3,500 |
| Dec. 10, 1902.......... | 45 | 3,021,000 | 2,000 |
| Jan. 20, 1903.......... | 50 | 3,290,000 | 1,000 |
| March 26, 1903.......... | 30 | 3,800,000 | 3,200 |
| April 27, 1903.......... | 50 | 3,768,000 | 5,000 |
| June 5, 1903.......... | 58 | 4,324,000 | 4,000 |
| Average............ | 48 | 3,678,000 | 3,230 |

A differential count of leucocytes was also made the last time that she called at my office, a week ago. Altogether 250 leucocytes were counted, of which there were 12 large lymphocytes, 42 small lymphocytes, 182 polymorphonuclears and 14 eosinophiles. In this count there were also noticed 13 normoblasts and 10 megaloblasts. There was no poikilocytosis. The daily quantity of urine recently has been about 30 to 40 ounces, and the last specimen of urine examined was cloudy, acid, specific gravity of 1016, a small quantity of albumin, a few granular casts and considerable pus.

The term "splenic anemia" is not an old one. Many of the older, and even some of the newer, text-books do not use the term at all, though the terms "pseudoleukemia," "primary splenomegaly," "splenic anemia," and "Banti's disease" have been used more or less synonymously for some time. Wentworth says the name "splenic anemia" was "employed first by Gretsel and Greisinger in 1866 to describe cases of severe anemia associated with chronic enlargement of the spleen. Greisinger believed these cases to be the splenic form of pseudoleukemia." In 1870 H. C. Wood of Philadelphia reported several cases of pseudoleukemia, only one of which, however, was quite typical of the condition as considered in more recent years. Osler says that to Wood belongs the credit of first presenting the subject to the profession in this country. There were recognized two forms of pseudoleukemia previously, one in which the lymphatics alone were involved, and the other in which the lymphatics and spleen together were involved. Wood said: "I now desire to show that there is still a third form of pseudoleukemia—a splenic variety. Under the names, tumor of the spleen, splenic cachexia, etc., from time far back, medical records furnish accounts of cases which I believe represent this affection."

There is no doubt that one of Wood's cases was typical, though even that case had some glandular enlargement. And to him no doubt also belongs the credit of priority in this country which Osler gives him, though Woods himself did not use the term "splenic anemia," and his report appears as "A Case of Splenic and Lymphatic Hypertrophy Without Leucocythemia (Hodgkin's Disease, Adenia, Pseudoleukemia)," and it is probably on account of the title of his paper that the paper has been overlooked by some. In response to a note to Dr. Wood, in which mention was made of such credit belonging to him, he said: "I was not aware that I had the honor you speak of in your letter, but I did know that my older papers had been absolutely overlooked by some among American literature on the subject." Since 1866 and 1870, however, the term has been used quite frequently both here and in Europe, and a considerable number of cases have come into literature. The subject has been studied carefully by both physicians and surgeons. But with the single exception of Dr. Osler it has not been the fortune of any one to see more than a few cases. Both Wentworth and West have said within the last few years that aside from Osler's cases there are perhaps not more than 30 authentic cases reported. This number is no doubt too low. But in the last few years several new cases have been

TABLE OF THIRTY-FOUR CASES OF SPLENIC ANEMIA.

reported and I add one more to the list. The subject has been most thoroughly discussed at recent meetings of the Association of American Physicians. And though the name splenic anemia seems to have found a place in literature, some very good observers, including Musser and Stengle, still claim that the condition does not deserve a separate term and place. Wood in his original paper came to several conclusions, two of which I shall mention: 1, "Clinically, the so-called true and false leukemia are the same, save only in the matter of white blood corpuscles"; 2, "all varieties of leukemia are represented in pseudoleukemia."

Osler has collected a series of 45 cases, excluding 17 of his own, from the members of the Association of American Physicians. Of these 45 cases 12 were of an acute type whose duration was from a few weeks to less than a year, 26 were of a chronic type, many of them having been afflicted for many years. The remaining 7 were not classified as either acute or chronic. Reports of these cases were submitted to him by such men as Dock, Musser, Cabot, Kelly, Herrick, Rotch, Wilson, Stockton and others of like recognition. From the limited report which he gives of these 45 cases (many of them perhaps unpublished) one is led to inquire whether all of them were in reality cases of undoubted splenic anemia. Some of them seem to be lacking the bulk of the physical signs of this condition.

In 1883 Banti described the condition and reported 3 cases. In 1894 he contributed further on the subject. In those papers and others published later especial reference is made to the enlarged spleen, also the enlarged liver and the absence of any glandular enlargement. On account of his evidently very accurate descriptions the malady occasionally has taken the name "Banti's Disease." While such credit may be due to Banti there are quite a few who believe that the term should be applied, or can be applied only to the latest and most marked stages of splenic anemia. We have, therefore, the terms "primary splenomegaly (found most frequently and typically in children and infants), "splenic anemia," and "Banti's Disease," all indicating perhaps different stages of the same condition, namely, a splenic variety of pseudoleukemia. To Osler belongs the credit, without any possible doubt, of having given to the profession the greatest number of most accurately reported cases of this kind. But the most complete description, perhaps, of the nature of the affection was given by Sippy of Chicago in 1899; and the most complete discussion of the literature on the subject, it seems to me, was given in 1901 by Wentworth of Boston. Wentworth, in a general way, discussed the subject "Association of Anemia with Chronic Enlargement of the Spleen," but many of his 88 references are to papers dealing almost exclusively with the subject of splenic anemia.

The symptoms of the disease are mainly anemia with low color index, and very commonly leucopenia; splenic enlargement often to the most marked degree; and a tendency to serious, and sometimes even fatal, hemorrhages. Other signs, as melanoderma, enlarged liver, ascites, swelling of the feet and legs, gastrointestinal symptoms, disturbances of the heart and kidney, irregular temperature and cachexia are also frequently present. The duration of the disease is from a few weeks to 15 years or more. You will notice that the case which I have presented showed about all these physical signs. Of the pathology nothing need be said here, and of the etiology only a word. Banti and others have regarded this as a primary anemia, and until we know of a more definite pathology and etiology of any of the primary anemias they can not be considered otherwise. With reference to splenic anemia, though, the profession seems to be looking toward the liver and portal circulation rather than toward the spleen for some causative factor. Barr thinks that the disease is secondary to vasomotor paresis of the abdominal circulation caused by some lesion in the visceral sympathetic ganglia. This theory has some support, though there are many who think that there are multiple causes rather than a single cause for all of this physical change.

The treatment of the disease has been both medical and surgical, of which neither seems to be very satisfactory. Harris and Herzog have collected reports of 12 recoveries from operations on 17 cases, the operation being, of course, splenectomy. To this number they added two more successfully operated cases. Osler has had four cases operated on with three deaths, hemorrhage having interfered much with the operations. Sippy is of the opinion that surgery alone is the proper treatment of this disease when the case is seen early. But he also says: "In reviewing the literature of splenectomy it is exceedingly difficult in many cases to determine the nature of the disease for which the operation was performed. As a rule, the operator has been more concerned in the technic of his operation than in the nature of the pathologic process for which it was performed." And though many patients pass through the danger of hemorrhage and shock from the operation, this does not prove that splenectomy removes the pathology of the disease in spite of the fact that many seem to improve after the operation. Somewhere I have seen the report of a case that died of gastric hemorrhage two years after a successful splenectomy and supposed cure of the case. Such a report adds strength to Barr's theory that the primary cause is not in the spleen, but in the visceral sympathetic ganglia.

Inasmuch as the case which I have reported has had much albumin, a number of casts and pus at times and as the disease is already of more than three years' duration, with a very much enlarged spleen and liver, with occasional ascites and much anemia, and inasmuch as the case has improved somewhat on a symptomatic treatment I hesitate to advise the risk of operation in her case, though appreciating fully the danger of another hemorrhage such as she had a year ago.

From considerable literature on the subject I have collected and tabulated the following cases, and will add the summary. Cases of primary splenomegaly in infants are not included in this list. All are undoubted cases of splenic anemia or Banti's disease, and with one exception all are adults. From what has been said before one would think it an easy matter to tabulate a hundred or more cases, and I must confess that this list is small, since half of the number has come from the writings of one man alone. But on account of the limited report which many of the authors give of their cases it has been found somewhat difficult to give a very large complete report of cases in the time which has been at my command. However, the following data may be interesting to some. Of the 34 cases collected 26 were males, 8 females and the average age was 30 years. A history of malaria was found in but 7 cases and of syphilis in only 2 cases. Melanoderma was present in 17 cases. Splenic enlargement was well marked and the most prominent feature in all of them. Hemorrhage occurred in 24, hemorrhage from several sources in the same individual not uncommonly. Of these 34 cases 15 had hemorrhage from the stomach, 8 from the nose, 7 from the bowels, 1 from the mouth and gums, 1 from the kidney and 1 from the genitalia. Next to splenic enlargement the anemia was the most striking symptom, being well marked in all of the cases, with a low color index and usually a leucopenia. In only two cases was there an excess of leucocytes. The average percentage of hemoglobin was 47 per cent., average number of red blood corpuscles 3,293,000, and of white corpuscles 5,594. If we exclude the two cases in which there was a leucocytosis, the average number of leucocytes is 4,381. The liver was enlarged in 16 cases, small in one case (Benedict). Ascites was present in 7, swelling of the feet and legs in 9, glandular enlargement in 3, gastrointestinal symptoms in 8, and cardiac murmurs, generally hemic, in 11. In only two cases aside from my own is there any report of albumin in the urine and then "only a trace," while my case has had considerable albumin at times, as well as some pus and casts.

The summary of the treatment and its results is most interesting. Of the 25 cases which were treated medically only 5 are recorded as "recovered," 12 were improved, 1 "not improved," and 7 died, hemorrhage having been the most common cause of death. Operation was performed on 8 cases, of whom 5 recovered and 3 died.

# SQUINT.*

ALBERT B. HALE, M.D.

CHICAGO.

Squint ought to be made an annually discussed subject at mothers' meetings, for it is through the mother that it must be detected, if this improper functional condition is to be corrected. It is not merely a question of two good eyes, although physiologically we need all our organs in the best of working order; cosmetically, the individual is nearer the type of perfect man if he not only sees with both eyes at once, but if the intended relationship of one visual axis to the other is constantly maintained; if no squint is observable. The young adult feels the effect of a cosmetic imperfection very keenly, and is grievously disappointed to find, when treatment or cure is sought, that the operation does not always lead to even cosmetic improvement, and that in the great majority of cases the squinting eye, if it does not persist in squinting, is, after all, a rather useless organ, on which no trust can be placed.

The correction of a squint, and if possible the restoration of function, must, then, be begun in early childhood. This is a fact not so much known, nor so usually accepted, even in our own profession—not even among all physicians who make a specialty of the eye—and the family counselor is sometimes guilty of saying that the child will outgrow its squint, or that the time to heal it, perhaps to operate on it, is about or after puberty. No greater error can be made. The time to treat a squint is as soon as it is noticed, which is very early in life, and the causes of the squint must be well understood before this advice is taken to heart and any treatment attempted.

Let me emphasize this statement: that many completely blind eyes do not squint—they jog along with their fellows content to obey the impulses from the brain without protest or discontent. On the other hand, most squinting eyes do see something, or did earlier in life, and at the beginning of the trouble they protested vigorously at the impulses from the brain and tried to act by themselves; tried to see something till they fell into bad habits, and long after they gave up trying to see accurately, they continued these bad habits and can not be reformed.

What, then, is squint? Of course, there is a paralytic squint, due to some acquired interruption to the nerve impulse or to injury to the muscle, but these are always characterized by double vision and usually come on later in life, through disease or trauma after the fusion faculty has been established. This may be called an organic lesion. The type to which I refer is, in contrast, called concomitant squint and has its origin in a functional disturbance, and the disturbed function is that of fusion. It arises early in life before the function is well established, and not being such a long-inherited function or instinct—for we know that binocular single vision is possessed by but few of the highest animals—it is easily disturbed. Generally, there is some exciting cause, such as a fever, a shock or fright, in childhood before the sixth year, while this habit is becoming acquired, and when weakened or lost, it is so delicate a function that neglect may often destroy it altogether, while to re-establish it demands attention, training, or the stimulus to spontaneous exercise of the habit, by placing the eyes in such relationship to each other that it is as easy to exercise as it is to neglect this function.

Herein lies the great error on the part of both physician and parent, the assumption that the child will *"grow out" of the habit of squinting. Perhaps he will,* but in the great majority of cases only at the expense of the vision of the squinting eye. Once have it well understood that treatment should begin early, as soon as the defect is seen, and there will be fewer squinters in the world, more sound eyes, and less complaint that the operation so seldom accomplishes what is expected of it.

The diagnosis is easy. Any layman can tell when a child or adult squints. but the etiology in the light of modern study shows that neither nerves nor muscles are primarily at fault. It is the brain, where the fusion function is located, and it is the brain we must first educate before we can hope to control the eyes. Usually —not always—one eye will be found to see less distinctly than the other eye, the difference in degree varying with the individual and the duration of the squint. The result of disturbed fusion sense is imperfect innervation, exaggerated accommodative effort in one eye—squint.

The treatment resolves itself into three factors: (1) Correction of refractive errors; (2) training of fusion sense; (3) operation.

Of these, the first is the essential factor, and without it practically no case of squint can be overcome, or if the eyes do later in life grow straight, it will be at the expense of the vision of one eye.

The second factor is of great importance, and implies such methods as the occlusive bandage, perhaps atropin to the good eye, stereoscopic, amblyoscopic and other visual exercises.

The third factor is operation, which is usually necessary, though squint may be entirely overcome without it. As a rule, however, some operation on a rectus muscle is necessary, and my later preference is for the advancement of a rectus muscle.

103 State Street.

* Read before the Chicago Medical Society, 1903.

## A CLINICAL NOTE ON OBSCURE CASES OF SEPTIC FEVER.

LOUIS FAUGERES BISHOP, A.M., M.D.
Physician to the Lincoln Hospital.
NEW YORK CITY.

There is a great defect in medical literature, in that men write chiefly concerning those things which have been impressed on their minds as well-defined pictures. The result is that there are whole classes of cases that do not receive that attention which would lead to a comparison of ideas, thus rendering them more clearly understood.

To illustrate: Every year two or three cases come under my observation, which I can best describe as cases of septic fever of obscure origin. In many instances they have proved very puzzling. The temperature, which is the principal symptom, runs an irregular course. The rise in temperature may sometimes be preceded by slight chills, but these are not particularly striking. The patient loses flesh and strength and presents the appearance of being slightly septic.

These are cases involving a great deal of responsibility, because it is so difficult to exclude local disease that should be treated surgically. It is difficult to exclude tuberculosis, and hard to be sure that the patient has not typhoid or malaria.

As a rule, recovery takes place after a long course of irregular temperature, but some have been fatal, one developing malignant endocarditis and several dying of exhaustion. One case developed an acute pleurisy shortly before death. and this was the only lesion found at autopsy. It should be the office of the bacteriologist to discover the nature of the difficulty.

I have no doubt that this brief description will call to the mind of every practitioner many such cases.

The best treatment I have discovered is forced feeding, with the use of a moderate amount of alcohol and tonics. Particular attention should be given to the abundant ingestion of eggs and milk. We have no specific to combat the action of the germs, so we must fortify the inherent power of the blood to defend itself, and this is best accomplished by attention to nutrition.

54 West 55th Street.

## THE RED CROSS SOCIETY OF JAPAN.

N. SENN, M.D.
CHICAGO.

When the writer made the trip around the world in 1901 it was not difficult to foretell that war between Russia and Japan was only a question of a few years. All through Russia and Siberia active preparations were being made for the inevitable conflict. Japan was ready at that time to meet its formidable foe. The strained relations between the two countries continued longer than I had reason to anticipate from what I saw and heard on both sides. The desperate struggle for supremacy in the far East has commenced, and from present indications it threatens to develop into what historians of the future will describe as the great war of the twentieth century.

We physicians are less interested in the political aspects of this war than in the treatment of the sick and wounded on both sides. Russia has always been the staunch friend of the United States, and our nearer neighbor, Japan, which has so recently taken its place among the international powers, has earned our respect and friendship by its progressiveness and dignified conduct in peace and war. It is a source of comfort to know that the present war, regardless of the proportions it may reach or the length of time it will last, will be conducted on the most humane principles, compatible with active warfare. It will be stripped of all barbarities that have until within a few years disgraced the battlefields of the past. Both armies are supplied with the small caliber weapon, and both armies are in care of well-educated and efficient medical officers, and are followed by a sufficient number of well-trained members of the Red Cross Society to care for the sick and wounded.

The Red Cross Society of Russia is the richest in the world, having $8,000,000 in the treasury at the present time; it is well organized, and will do efficient service from the very beginning. The Red Cross Society of Japan has a membership of 800,000, with ample means to extend its work to the seat of conflict, at any rate for a number of months.

The writer has the honor to be a life member of the Red Cross Society of Japan, and as such offered his gratuitous services when war was declared. The daily press, unfortunately, has circulated distorted reports which have caused no end of confusion in the minds of professional men and nurses. I have been for a number of days fairly deluged with letters from doctors, students and nurses from all parts of the country, offering their services. Neither Russia nor Japan need any outside help in the care of their sick and wounded for the present, and it is only in case the war should be prolonged for six months or more that the Red Cross societies of other countries would extend a friendly hand. In such an event Germany will assist its neighbor, Russia, and we in the United States would naturally extend the work of our national Red Cross Society to Japan. Miss Clara Barton, the president of our American Red Cross Society, who is a veteran in this kind of work, is undoubtedly making all necessary preparations at this time to step in at a moment's notice should occasion arise. The profession looks to her to take the necessary steps when the proper time arrives.

The public and the profession have, on the whole, a wrong idea of what Japan can do for the sick and wounded of her army now in deadly combat with the most formidable military power in the world. It is for this reason I am desirous to inform the readers of The Journal of the American Medical Association of the present status of the Red Cross Society of Japan.[1]

The noblest of the many charitable institutions that have sprung up in Japan since this country opened its doors to the outer world is the Japanese Red Cross Society. Since the organization of the Geneva convention by Henri Dumont in 1864, most of the civilized nations of the world have established Red Cross societies for the purpose of minimizing the horrors of war, and to render aid to the victims of great catastrophies. In no other country have these humane efforts met with such unparalleled success as in Japan. This is certainly a startling statement when we remember that modern civilization was introduced into this country less than fifty years ago.

The Red Cross Society of Japan was founded in 1877, during the insurrection in the southwest provinces. It had for its object the relieving of the wounded and sick on the fields of battle, and the taking care of them, for this it adopted the name of Hakuaisha (Society of Benevolence). After the rebellion was crushed the society made itself a permanent organization and decided to make ample preparations for similar emergencies. When the imperial government recognized the articles of the Geneva convention, the society decided to strengthen its bases and to extend its operations, to place itself in connection with the International Committee of the Red Cross at Geneva, and to enter into fraternal relations with similar societies in friendly countries. This resolution, having been adopted at a general meeting, the society, with the approval of the ministers of the imperial household, of war, and of the navy, changed its name to "The Red Cross Society of Japan," and adopted rules and regulations for its government.

The growth of the society has been phenomenal. It has at present 800,000 members, which simply means that nearly every family is represented, estimating the population of the country at 45,000,000. What has achieved this unparalleled success? By what means has Japan outstripped every other country in making provisions for the disasters of war and other great national calamities? These questions are not difficult to solve for anyone who has seen the workings of the Japanese Red Cross Society. The imperial family takes a deep interest in this organization, and contributes liberally to its funds. An imperial prince is its honorary president, and a princess the president of the ladies' committee. The empress is a frequent visitor to the headquarters of the society and to the Red Cross Hospital. This noble example is a potent factor in arousing popular interest in this national institution so dear to every Japanese. Then again, the imperial family has the utmost respect for the leading medical men. Baron Ishiguro and Baron Hashimoto, the most influential medical men of the Japanese medical profession, have been the guiding spirits in promoting the growth and usefulness of the society, and their efforts have been supported by a united loyal profession. The Japanese are easily reached and led by such powerful influences, and have responded promptly and liberally to such noble examples.

---

[1] I shall quote freely on this subject from my book, "Around the World via Siberia."

Popular interest is aroused annually by a great public gathering of the members of the society from every part of the island empire, at which lectures are delivered by medical men, illustrated by magic lantern pictures showing the actual practical work of the society. These meetings are usually held in the Uena Park, Tokio, and the attendance is seldom less than 200,000. Baron Ishiguro informed me that the lantern illustrations attracted a great deal of attention and contributed the most in popularizing the society, and as a means of practical instruction in first-aid work. Then, too, it must not be forgotten that the Japanese people are fully imbued with the spirit of progress, and that they are well aware that they have entered a stage of international life that may bring at any time serious emergencies they may be called on to meet; in other words, they believe in making ample preparations for war before the war clouds make their appearance, and it is for this reason that the present war did not come as a surprise.

The headquarters of the society are in Tokio, and consist of a number of buildings for the central office and store rooms. It was through the courtesies of Barons Ishiguro and Hashimoto I was privileged to inspect every department as well as the military schools and hospitals. The central office is a capacious, well-lighted room luxuriously furnished. Here the committee meetings are held. Adjoining this room is one set aside for the imperial family. The elegant furniture and magnificent oil paintings of the emperor and empress impart to this room the aspect of royalty. It was the contents of the storerooms that astonished me, and that gave such vivid evidence that Japan was well prepared for war, the amount of hospital supplies being something enormous. Stacks of uniforms and black dresses and white caps for the female nurses, lanterns, canteens, blankets, bedding, cots, medicines, tents, wagon loads of dressing material, field chests, litters, and trains of ambulances filled the many capacious rooms to their ceilings. Within a day or two the Japanese Red Cross Society can load a hospital ship or railroad train and leave for the seat of war without causing the least anxiety or confusion. The surgeons and nurses are ready at all times to respond to the call, and the arrangements of the hospital stores are so systematic that they can be transported in the shortest possible space of time. The Red Cross surgeons and nurses, male and female, are under military rule and do their work in the hospitals behind the fighting line.

The society owns and operates two hospital ships, the Hakuai-Maru and the Kosai-Maru, admirably constructed for the transportation and care of the sick and wounded.

The Red Cross Hospital in Tokio is the best of the many good hospitals in that city. It is in this hospital that the Red Cross female nurses receive their education and training. It has a capacity of 250 beds, and is attended by a staff composed of the very best physicians and surgeons of the city. The central figure of the staff is Baron Hashimoto, one of the retired surgeons-general of the army. The nurses receive the most practical kind of instruction by lectures and demonstrations given by members of the staff. They are made nurses, and not half doctors, as is the case with many of our training schools. They serve an apprenticeship of three years, and on passing a satisfactory rigorous examination receive the necessary credentials, which entitle them to enter private practice, and in the event of war they enter the field service under military rule. These nurses compare well with the trained nurses of our own country, and it seemed to me that in many ways they are better adapted for service in the field, as their needs are few and their quiet, gentle behavior can not fail in securing for them the respect and confidence of the disabled soldier.

From the above it may be gleaned that the Red Cross society of Japan is well prepared to meet the emergencies of the present war, and that outside help, at least for the present, is not called for, and should such an event arise it will become the duty as well as the pleasure of the Red Cross societies of other countries to bring the needed relief. The experience of the last few days has demonstrated again the innate nobility and unselfishness of our profession. I have received and placed on file nearly 500 applications for medical service in Japan, more than half of them from physicians. These letters prove that the commercial spirit so rampant in many localities has not infected the entire profession. Less than twelve of the applicants referred to financial considerations, most of them offered their gratuitous services, and not a few were willing to defray their own expenses, certainly a record of which we have reason to feel proud.

As this article goes to press I receive the following telegram from Baron Hashimoto in reply to my request for gratuitous service in connection with the Red Cross Society of Japan:

TOKIO, December 15.

*Dr. Senn, Chicago:*

Regrette ne pouvoir accepter votre proposition.

HASHIMOTO.

This message only confirms what I have said concerning the efficiency of the Red Cross Society of Japan, and should, for the present at least, check further applications for medical service in Japan.

## Clinical Report.

### ECTOPIC PREGNANCY

TWICE IN THE SAME PATIENT WITHIN FOURTEEN MONTHS—OTHER CASES.

FLORUS F. LAWRENCE, M.D., D.Sc., LL.D.
Clinical Lecturer, Diseases of Women and Abdominal Surgery, Starling Medical College; Chief of Staff and Surgeon to the Lawrence Hospital.
COLUMBUS, OHIO.

The question of leaving an apparently healthy fallopian tube when the opposite one is the site of an ectopic pregnancy has been and still is debatable. The following case is one more clinical argument to be added to others and to clinically reinforce the logical arguments (based on pathologic findings) in favor of removing both tubes or at least obliterating the apparently healthy tube.

Mrs. O. A. S., a physician's daughter, aged 26. Seen in consultation with Dr. C. S. Carr, May 3, 1902. She is a well-nourished, robust woman, mentally and physically much above the average; has been married 3 years, and never has been pregnant, so far as she is aware. She has never missed menstruation. She has marked neurotic disturbances. Her father found on examination a tender mass to the left of the uterus, which, together with other symptoms, made him suspicious of an ectopic pregnancy. May 3 he called me. On examination I found to the left of the uterus a mass which, on careful investigation, proved to be undoubtedly the enlarged fallopian tube, of the peculiar consistence found only in unruptured ectopic pregnancy. A diagnosis of extra-uterine pregnancy was therefore made and the patient immediately removed to the Lawrence Hospital and prepared for operation. The operation was performed May 4 and a left tubal pregnancy removed (Fig. 1). At the request of the physician and the patient, the right tube, which was apparently healthy, was left.

June 24, 1903, Mrs. O. A. S. called me to see her again. I found her presenting the symptoms of pregnancy, and on examination found all the physical signs of an early pregnancy with the additional unwelcome sign of thickening and some tenderness of the right fallopian tube. I saw her again on July 1, at which time the enlargement of the tube was so marked that I called the attention of her father to it and told him that I very much feared we had another ectopic pregnancy. From this time I saw her every day or two until July 24, when Dr. D. N. Kinsman saw her with me, and agreed in the diagnosis of ectopic pregnancy. She was admitted to the Lawrence Hospital July 25, operated on July 27, and an unruptured right tubal pregnancy removed (Fig. 2) The tube was almost ready to rupture.

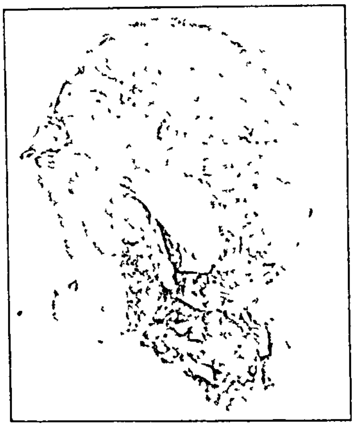

Fig. 1.—Tubal pregnancy.

This is one of three cases coming under my observation in which leaving the apparently healthy tube resulted in like manner. One of these occurred while I was assistant to Lawson Tait. The patient had been successfully operated on by a German surgeon for a right-sided tubal pregnancy two or three years previously. Mr. Tait was called to operate on her for a ruptured left tubal pregnancy in November, 1894, and I assisted in the operation. He said then: "To leave a fallopian tube in a woman who is the victim of extra-uterine pregnancy is to needlessly, if not criminally, endanger her life in the future."

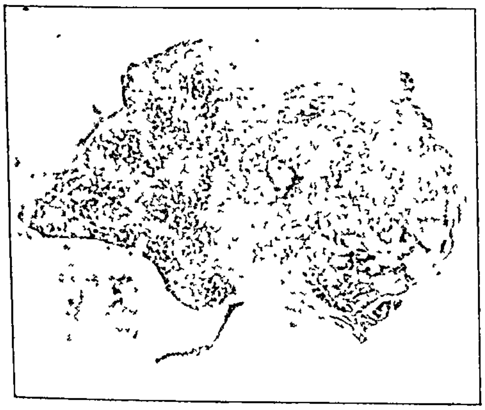

Fig 2—Tubal pregnancy

Another case was Mrs. G. H. E., on whom I operated March 9, 1897, removing a pregnancy of the left fallopian tube June 17, 1901, I was again called. She was moribund, and died very soon. A postmortem showed the abdomen filled with blood from a ruptured ectopic pregnancy of the right fallopian tube.

The present case of Mrs. O. A. S. forcibly emphasizes the danger of such a practice. It should be remembered that ectopic pregnancy never occurs in a normal condition of the uterus and the fallopian tubes; that there is always a preceding tubal disease; that the particular form of tubal disease, viz., desquamative salpingitis, is bilateral; that there is practically always an accompanying localized peritonitis affecting the tubal covering; that the consequent probability of a normal pregnancy is slight; that the danger of an unrecognized or unsuspected tubal gestation can not be estimated; that extra-uterine pregnancy may go to rupture before it is suspected, and that ruptured ectopic pregnancy is very apt to be fatal.

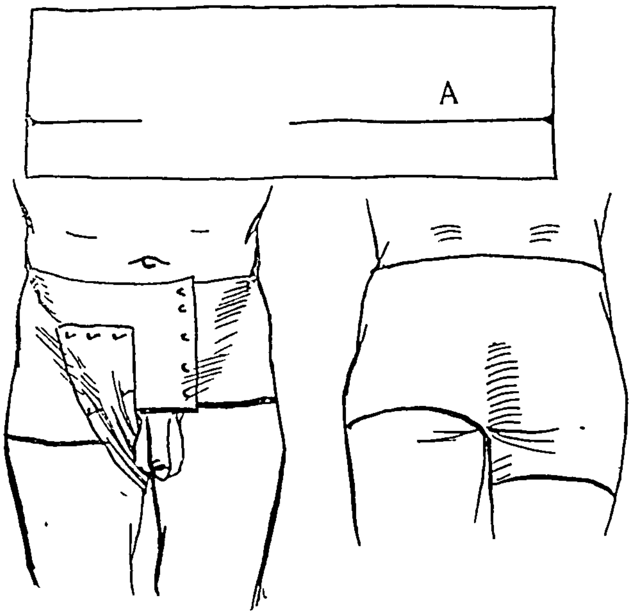
## New Appliance.

### AN INGUINAL BINDER.

ALLEN B. KANAVEL, M.D.
CHICAGO.

Any surgeon who has dressed a suppurating limb or examined an inguinal operation and as a consequence redressed the wound with a spica or some variety of a roller bandage, will appreciate a suggestion which enables one to do this with little trouble, and yet make a dressing that is more comfortable to the patient and more satisfactory to the surgeon.

Take an ordinary abdominal binder, measure off about four inches width at one end and tear the cloth half its length. (See A in the illustration.) Now apply the binder with the untorn end on the side where the wound is to be dressed. The tear in the goods will then extend to the median line posteriorly at the tip of the sacrum. Now tear the other end, taking a corresponding width down to the inguinal region, i. e., the untorn part will extend from the median line posteriorly around the leg of the affected side to the inguinal region. Now the wider part is applied as any abdominal binder. The narrower ends are brought around the leg of the affected side, the short end being pinned to the longer, the end of which in turn is brought up over the wound on to the abdomen and fixed. As the dressing now stands, by removing the three or four pins which fix the tails the wound can be easily uncovered and redressed; moreover, it is very comfortable to the patient, the wound never becomes uncovered, and the dressing simply can not come off.



6027 Prairie Avenue.

**Isolation of Tuberculous Pupils.**—In an address on "Tuberculosis from an Educational Standpoint," before an organization of public school principals in Chicago, Dr. George W. Webster, president of the Illinois State Board of Health, recommended segregation of such public school scholars as should be found to have pulmonary tuberculosis He urged a state sanatorium for the care of tuberculous persons

## THE TREATMENT OF DIABETES.

Notwithstanding the large amount of research work which has been done on diabetes mellitus and the number of articles which have been written on its physiologic treatment, the disease is still improperly treated by too many physicians. The explanation doubtless lies in the lack of facilities for quantitative examinations of urine, and in the lamentably slow spread of that newer knowledge of the body metabolism, on which the rational treatment of diabetes mellitus is based. In the treatment of diabetes, more than in perhaps any other disease, a little knowledge may be a dangerous thing. At the New Orleans session of the American Medical Association, Osborne, Robinson, Elliott and others[1] made some very emphatic statements along this line. It was said, in effect, that, without doubt, many diabetic patients would be better off, would live longer and would live more comfortably were the existence of the disease never discovered in them; and that the fact can not be denied that the accidental discovery of sugar in the urine of an apparently well man at a life-insurance examination has led in many an instance to the undertaking of a therapy which has done more harm than good.

In the treatment of diabetes, two classes of cases are to be distinguished—the mild and severe. The differentiation is easily made. If the patient be placed on a diet entirely free from carbohydrates for a few days, the sugar will entirely disappear from the urine if the case be a "mild" one, while if it be "severe" some sugar will continue to be excreted in spite of the rigid diet. Should the case be of the "mild" type, the tolerance of the patient for carbohydrate food should next be established. By giving 30 grams of white bread, in addition to the albumin and fat of the rigid diet the first day and increasing the amount of white bread by 20 grams daily until sugar begins to reappear in the urine, the patient's capacity for oxidizing sugar can easily be determined. This having been done, the patient, if placed on a diet somewhat poorer in carbohydrates than that corresponding to the level of his tolerance, may very gradually be given a diet richer and richer in carbohydrates without the reappearance of sugar in the urine, until finally he may be able to resume a normal diet. In other words, judicious dieting of the diabetic patient increases his capacity for the oxidation of sugar, whereas if his diet be neglected and he be permitted to eat what he likes, his capacity for oxidizing sugar diminishes, and a case mild at first and perhaps curable, may quickly be converted into one of the severe type.

Practically all mild cases feel better when the urine is thus kept free from sugar. The hunger grows less, the thirst diminishes, the weariness disappears, and there are fewer nervous symptoms. Occasionally, however, a "mild" case does not do well on this treatment. If the patient begins to emaciate and to feel very tired, the amount of carbohydrate food should be increased, even if the urine does not remain entirely free from sugar, for here the general feeling of well being on the part of the patient is the physician's best guide. Much can be done, too, to add to every patient's comfort by varying the form in which the carbohydrate is given at the different meal times. With the aid of the tables now available, the equivalent of the starch of a given number of grams of white bread in say rice, potatoes, maccaroni, fresh peas or green beans, or in the various forms of "diabetic bread," may easily be ascertained, and the carbohydrate food should, once the tolerance has been established, be varied as much as possible.

In the treatment of cases of the "severe" type, it is not practicable to proceed so schematically as in the treatment of cases of the "mild" type. The "severe" cases, on a diet entirely free from carbohydrates, still excrete sugar in the urine, the body being unable even to oxidize the carbohydrate moiety of the breaking-down molecules of albuminous food. But it would be a grave mistake to keep such patients for a long time on a diet entirely free from carbohydrates with the idea of reducing the sugar in the urine to a minimum. Even the normal body with a diet free from carbohydrates, will begin to build acetone and aceto-acetic acid and later beta-oxybutyric acid, and these substances will appear in the urine. Every diabetic patient placed on the rigid diet soon begins to excrete these bodies in the urine, and if acetone does not appear, the physician may be sure that the rigid diet prescribed has not been adhered to. The rule, then, in severe cases, is t begin with a rigid diet. If the acetonuria which come at first, disappears again, and the patient in general feel better, it may be continued; but if the acetonuria i intense and beta-oxybutyric acid begins to appear in th urine, the rigid diet should not be continued, bu enough carbohydrate given to make these organic acid disappear. There seems no longer to be any doubt tha the graver nervous symptoms of diabetes, including th much-dreaded diabetic coma, are directly related to th presence of organic acids in the blood; it is, therefore much more important in the severe cases to prevent acid-intoxication than to keep the urine free from sugar.

In conclusion, then, it may be said, that in "mild" cases as much carbohydrate as possible should be given as long as the urine remains free from sugar. The patient goes into "carbohydrate-training," as it were, to increase his tolerance by augmenting his sugar-burning power. In the "severe" cases, as much carbohydrate should be given as is necessary for the general well being of the patient and for the prevention of acidosis. The rigid diet entirely free from carbohydrates should, therefore, in such cases be avoided, and the acid-intoxication may also be combated by the administration of 10 grams of bicarbonate of soda in the twenty-four hours.

## THE REMOVAL OF GOUTY TOPHI AND URATIC CONCREMENTS.

The caprice of fashion in therapeutics has been, perhaps, nowhere more evident than in the series of methods which, from time to time, have been introduced for the treatment of urate deposits and the so-called "uric-acid diathesis." Nearly every method has been an attempt at rational therapeutics; a particular drug has been employed because, according to the theory in vogue, it increased the solubility of uric acid or its salts. Strangely enough, modern inquiry has shown that in nearly every instance the theory lying at the basis of the "rational" therapy has been false; and the discarded group of remedies occupies a goodly area in the therapeutic rubbish-chamber.

Since Pearson, in 1798, recognized uric acid as a constituent of gouty deposits, efforts have been made to find a suitable solvent for them. The alkalies have, perhaps, had the longest trial. Borax was at first widely employed, but it gave place later to other salts of sodium and salts of potassium; and since Garrod's time the salts of lithium have been especially vaunted. Some have preferred a mixture of different alkaline salts, the uricedin of stroschein, for example. A new era seemed to be opened when it was discovered that certain organic bases increased the solubility of uric acid in water, and it was hoped that by the administration of piperazin, lycetol, or lysidin the woes of the gouty could be speedily ameliorated. These hopes, however, were doomed to disappointment; even china-acid, with its lithium salt, urosin, and its piperazin salt, sidonal, has been added to its obsolete forerunners. The failure of the whole group is easily understood when the defect in the theory is pointed out. While it is true that the bases mentioned above make salts which are more soluble than sodium urate in pure water, yet they can not be so in the blood or in the urine. For as His and Paul, applying the newer conceptions of physical chemistry to the problem, have shown, the solubility of any urate in the blood is diminished by the sodium salts of the blood. Thus the solubility of sodium urate, for example, is decreased by one-half in a sodium chlorid solution containing 0.046 per cent. of salt. Nor does it do any good to bring into the solution along with sodium urate other bases whose uric-acid salts are more soluble than sodium urate; for physical chemistry teaches that on bringing an acid together with several bases the first salt to fall out of solution is that whose "solubility-product" is smallest. It is obvious, therefore, that it is hopeless to effect the solution of uratic deposits through the direct action on them of solutions of lithium and piperazin, and it is further clear that the giving of sodium bicarbonate to dissolve uric-acid calculi must, as far as the direct action of the salt is concerned, make the deposit less rather than more soluble.

The empirical observation that gouty patients are benefited by the long-continued use of alkaline mineral waters must, therefore, be explained on grounds other than those usually assumed; the benefit must be due to some indirect metabolic effect rather than to any direct solvent action on the calculi or tophi. Uric acid in solution undergoes slight electrolytic dissociation into a hydrion and an anion, consisting of the rest of the molecule, urate of soda into the sodium cation and the same anion. It is on this dissociation that the reactions of uric acid and urates, as well as their solubility relations, depend. If now some substance could be found that united with uric acid in such a way that on solution the compound did not form the uric-acid anion on electrolytic dissociation but some other ion, the matter would be entirely different. Such complex uric-acid compounds might have entirely different reactions and solubilities. We are becoming acquainted with such substances. One of them is the thymus-acid of Kossel, and another is formaldhyd, the latter forming a series of compounds with uric acid, of which the best known is diformaldehyd-uric acid. The solubility of diformaldehyd-uric acid is about 1 to 400, an enormous solubility compared with that of uric acid, which is about 1 to 38,000. Acids precipitate uric acid from urate solutions, but not from diformaldehyd-uric acid solutions. It is possible that this substance would be soluble and resistant in the alkaline fluids of the blood and tissues.

One of the most interesting facts yet discovered in this connection concerns the fate of urotropin (hexamethylentetramin) when administered to human beings. In some way or another—just how is not known—it converts a part of the uric acid excreted in the urine into formaldehyd-uric acid. It is, however, as His has pointed out, far from being an ideal drug, for, aside from its irritating effects, even when as much as 6 grams are given per day it is capable of transforming only about one-fifth of the uric-acid output into the more soluble formaldehyd-uric acid. But urotropin therapy seems a step taken in the right direction, and we may hope that through the seething activity of the pharmaceutical chemist, some substance acting similarly but much more powerfully without harm to the organism may yet be discovered.

In the meantime, we have nothing better to offer our gouty patients than a well-regulated regimen—a carefully chosen rather spare diet, the interdiction of all alcohol, copious water-drinking, at least two hours' exercise in the open air daily, and appropriate balneotherapy and mechanotherapy. Where gouty deposits occur about the joints, most can be accomplished by the excitation of local phagocytic activity, and herein doubtless lies largely the efficacy of thermal baths, hot applications and local massage.

## SUICIDE IN CHILDHOOD.

It is contended by some that suicide is a symptom of mental aberration, but while such a view is not in strict accordance with the facts, it will be found that, apart from those unequivocally insane, the suicide is one who has been ill or has suffered loss or disappointment or ill treatment, real or fancied. Statistics show that suicide is increasing in frequency, and the reasons therefor are all too obvious. In the intense struggle for existence, in the eager contest for power, in the mad race for place and position, some must inevitably meet defeat and disappointment, and some must be left behind; and it is from among these that is recruited a large part of the army of those that seek refuge and oblivion in self-destruction. The burden naturally falls most heavily on those that have reached maturity, but children do not entirely escape, and it will perhaps be a matter of surprise to many to learn of the frequency with which suicide occurs among the young. Thus Dr. Ernö Deutsch[1] of Budapest has collected from various Continental sources 200 cases of suicide in children, and he refers to 49 additional cases collected by Siegert and to 50 collected by Ferriani.

The causes that lead up to the commission of the act are divisible into the general, predisposing, and the special, exciting. Lack of religious spirit has been assigned as a predisposing cause, but suicide is scarcely known among non-religious savages. It has been stated that suicide is more common in proportion to the degree of culture of a community, but this is notably not true of England. There is, however, a danger in the burden of excessive school work, so generally imposed on children at the present day, with its competitions and examinations, and its inevitable failures and disappointments. Disturbing political conditions and states of war are of influence only so far as they have an effect on the family. Poverty is a most important factor, the children being overwhelmed by the difficult and often unsuccessful struggle for existence on the part of the parents. Physicians and jurists have been inclined to look on the suicide as an abnormal individual, mentally deficient, and this has been found to be so actually in not a small number of instances. As in adults, the vast majority of suicides in children—up to four-fifths—occur in males. The largest number is observed between the ages of 11 and 15 years, and here, again, there is evidence of the important etiologic influence exerted by school work, suicide in children being most frequent toward the close of the school term.

The exciting causes may be single or multiple. Among the most important of these are punishment and fear of punishment, school matters, psychoses, domestic difficulties and vicious habits. The mode of death depends somewhat on the social position of the parents. Drowning is most common, then hanging, shooting and jumping from windows.

In view of the facts in the case it would seem that the remedy to be applied, in order to diminish the frequency of suicide among adults and children alike, consists in a return to a simpler and less strenuous mode of life, so that mental and physical strain shall be lessened and the measure of individual and communal contentment increased.

## VITAL STATISTICS.

The progress that has been made in collecting mortuary and vital statistics is a matter of congratulation to the medical profession. Sources of error are being eliminated, approved methods are receiving wider adoption, and the facts deduced from these figures are coincidently becoming more valuable and more authoritative. Occasionally there is an obstacle in the march of progress.

Almost every law requiring the reporting of births provides for the payment of a small fee to the reporter. The absence of such a provision in the law of St. John, N. B., has been, in part, the cause of the resistance of that law by the St. John physicians. We have mentioned this matter as news.[1] In protesting against this law, the medical men assert that by reporting births they violate the confidential relationship between them and their patients. They assert that they are made spies and informers, and they "object to being made statistical officers without our knowledge or consent and without remuneration." Of the question of privileged communication, there is an easy disposal, for, under the dominion law, concealment of birth is a criminal offense. It would seem that the physicians had left a very good chance for others to attack their argument on the ground that their strongest objection is that they are *not to be* paid for giving information required, and a lay paper[2] has very pointedly found this opening in their defense. It says: "We are left to infer that if they were paid for giving this information they would be willing to forget the confidential relationship referred to." The paper calls attention to the fact that the physicians of New Brunswick are well protected by law from competition with irregular practitioners, and that it would seem only fair for them to report births as a partial expression of their appreciation of the protection. The point is well taken. The restriction of the right to practice medicine to those who are properly prepared is in the interest of the public; so also is the law requiring the reporting of births. The latter requirement seems to us to be a duty of some one certainly—and to whom could it more fittingly be given than to the one who officiates at the birth of a new protégé of the government?

---

[1] The Journal, Nov. 21, 1903, p. 1280, and Jan. 16, 1904, p. 182.

[2] Fredericton (N. B.) Gleaner, Jan. 4, 1904.

The physician has always been, to some extent, an adviser in things medical of the powers that be, and he has desired even more of such an official capacity. The profession has always emphasized that medical matters should be under its control. There should be remuneration, of course, but that is a minor point. Regardless of the question of pay, it seems a step backward for physicians to object to reporting births.

### THE QUADRUPED CURE FOR APPENDICITIS.

Civilization and the unnatural habits into which men drift are held responsible for many conditions of ill health, and a more natural life would presumably relieve the difficulty. The latest cure for appendicitis, as announced by cable from Berlin, is for the patient to walk on all fours for twenty minutes, four times a day. The theory on which this treatment is based is that "certain muscles around the vermiform appendix are brought into play and strengthened by this quadrupedal cure, which are unused when a biped walks erect; others are relaxed and the localized inflammation has opportunity to subside." Exercise is often beneficial and a change of habit might pacify a grumbling appendix. Before long, therefore, we may see our hospital corridors and solariums full of patients walking on all fours like the majority of other animals. With this encouragement, atavism might cause a reversion to the chimpanzee type.

### POLITICS AND CHARITABLE INSTITUTIONS.

The *Illinois Medical Journal,* in its late issues, has been doing good work in calling attention to the needs of the Illinois state institutions. The greatest of such needs, both in Illinois and in many other states, is to be freed from their present incubus of political control which has ridden them for many years. Previous to 1893, the political element in the management of the Illinois state charitable institutions was of a comparatively mild and innocuous type; while it might be occasionally in evidence to their disadvantage it was not conspicuous, and to the general public these institutions were non-political. Up to about fifteen or sixteen years ago it was the rule to recognize the minority in the appointment of trustees, an arrangement not as ideal as ignoring politics altogether, but one that helped at least to keep partisanship out of these administrations. Of late years, however, matters have been getting progressively worse, partisanship has become the controlling force, and the public confidence and pride in the institutions have been to a large extent dissipated. The condition is all the worse in that it is in striking contrast with that of some of other states where better methods prevail. The Chicago *Tribune* takes up the *Illinois Medical Journal's* suggestions, and advocates the appointment by the legislature of a commission to investigate and report on the best remedy for the present evil conditions. It further remarks that the numerous candidates for governor at the present time have each a "big interrogation craning its neck at them," whether they will or will not further this investigation and expedite the introduction of a civil-service reform. The citizens of Illinois, and, we may add, of other states in which the trail of the spoilsman is over the charitable institutions, owe it to themselves and to the helpless charges of the state to see that a satisfactory answer is given. Civil-service reform may not be the cure-all that some anticipate, but it will be a vast improvement over the "slush fund" system of diverting appropriations made for charity to the uses of political partisans. The medical profession ought to be in the foreground in this reform, the need of which unfortunately is not confined to any one state. It is an encouraging feature of the situation that the political press, aside from party prejudices, as in the case above noted, is ready to take up the subject on the right side.

### ALCOHOL AS A FOOD, AGAIN.

The value of alcohol as a food can be efficiently tested only by extensive observation. Its determination in a purely academic sense is of no practical value or of special interest. It does not follow that, because it may be assimilated and may become a source of energy in the system, that it is a desirable or a useful article of diet. When we get down to hard business facts, such, for example, as the experience of life-insurance companies, we have a better standard by which to judge. In the *British Medical Journal,* January 16, is an abstract of a paper read at the meeting of the British Institute of Actuaries on the comparative mortality of abstainers and non-abstainers, based on the experience of the United Kingdom Temperance and General Provident Institution during the last sixty years. This insurance company takes both classes with the same premiums, but keeps separate records. The mortality experience of each grade separately is ascertained carefully, the former receiving no advantage arising from their superior vitality except in the form of additional bonus. The special feature of the case, as the *British Medical Journal* shows editorially, is that the abstainers show an advantage which is from 25 to 45 per cent. superior to that of the non-abstainers between the years of 25 and 65, that is, in the active and valuable years of life. The comparability of the two sections is thoroughly discussed. The average amount of insurance in each class is about the same. There has been no special selection of lives in the abstainers' class, and there is no question in case of their taking liquor under the prescription of a physician. The pecuniary conditions and methods of living other than as the drinking habits are alike. The members of the two classes are dealt with on absolutely equal terms, and the superiority of the life experience of the abstainers has not been obtained, as shown by careful statistics, by any preferences between the two classes. Our British contemporary, which, so far as we know, is not prejudiced in favor of total abstinence, says that the study of statistics fails to reveal any other cause for the condition than the abstinence from alcoholic drinks, and that, in the light of this experience, abstinence must be considered as an important factor in securing health and long-life. Such facts are far more significant and important in establishing what is the dietetic value of alcohol as commonly used, than is any amount of laboratory experimentation. They, moreover, agree with other experience from a medical and economic point of view. Therefore, total abstinence from alcohol seems to be decidedly the best policy for anyone who wishes to live long and to avoid any unnecessary risk to health and life.

## Medical News.

### ILLINOIS.

**Scarlatina Closes College.**—Concordia College, Springfield, was closed by the faculty, February 13, on account of an outbreak of scarlet fever. The students have returned to their homes.

**Donations to Hospital.**—William B. McKinley and Mrs. Newton M. Harris of Champaign have each given $10,000 to the endowment fund of the Julia F. Burnham Hospital in that city. The hospital's endowment now amounts to $31,721.50.

**Iroquois Memorial Ward.**—Members of St. Francis' guild will commemorate the deaths of associate members in the Iroquois Theater fire in Chicago, by endowing a ward in St. Francis' Hospital, Evanston, for the exclusive use of indigent patients.

**Little Typhoid at Canton.**—Dr. James A. Egan, secretary of the State Board of Health, has received reports from Dr. W. E. Schallenberger, health officer of Canton, that only 4 cases of typhoid fever now exist in that city, and that all infected houses are being thoroughly disinfected.

**Examination for Naval Reserve Surgeons.**—An examination will be held at Rush Medical College, February 27, of candidates for commissions in the medical department of the Illinois National Guard, for assignment to the Naval Reserve. The surgeon-general, Col. N. Senn, will preside, and he has designated as the examining board, Lieutenant-Colonel G. Paull Marquis, Major Charles Adams, and Captain S. C. Stanton.

#### Chicago.

**Increase in Diphtheria.**—The health department reports an increase of nearly 20 per cent. in the number of diphtheria cases reported during the week over the number reported the previous week.

**Personal.**—Dr. Robert B. Preble, president, and Dr. Frank X. Walls, secretary of the Chicago Medical Society, left Chicago, February 11, for a two weeks' vacation in Cuba. In their absence, the affairs of the society will be administered by Drs. William A. Evans and W. S. Harpole.

**Mortality of the Week.**—During the week ended February 13, 661 deaths occurred, 65 more than in the preceding week, and 27 more than for the corresponding week of 1903. The respective annual death rates are 17.68, 15.92, and 17.56 per 1,000. Pneumonia still holds a long lead with 175 deaths, the next on the list being consumption, with 71.

**Comparative Diphtheria Mortality.**—Between Oct. 5, 1895, the date of first case treated, and Dec. 31, 1903, the antitoxin administrators of the health department have treated 7,435 cases of bacterially verified diphtheria, of which number 479 died—a mortality rate of 6.44 per cent. The average mortality without antitoxin still remains at about 35 per cent.

**Pertussis and Measles Not Fatal.**—For the fifth consecutive week, says the bulletin of the health department, there has been no death reported from measles and none from whooping cough in six weeks. There was one death from each disease in January and none thus far this month. During the corresponding period last year there were 32 deaths from measles and 46 from whooping cough.

**Loving Cup Given Dr. Quine.**—At the annual reception given by the senior class of the medical department of the University of Illinois, February 9, in honor of Dean Dr. William E. Quine, which marked his fifty-seventh birthday anniversary, his thirty-fourth anniversary as a medical teacher, and his twenty-first anniversary as a member of the faculty of the College of Physicians and Surgeons, the class presented him with a silver loving cup.

### MARYLAND.

#### Baltimore.

**Personal.**—Dr. Harry C. Johnson, resident physician at Franklin Square Hospital, has resigned and will practice in Lucketts, Va. His resignation promotes Dr. Oscar H. McNemar to be resident physician and Dr. J. C. Hodges to be assistant. ——Dr. J. S. Bowen has returned from Europe.

**The Baltimore Fire.**—The medical schools and hospitals, being out of the line of the fire, escaped destruction, except the Maternity of the College of Physicians and Surgeons on West Lombard Street, which was totally destroyed. All the patients were rescued. The flames threatened the destruction of the College of Physicians and Surgeons and the City Hospital on North Calvert Street, but a sudden change of wind saved them. Before that, however, all the patients had been removed from the City Hospital to the Johns Hopkins, the University and Maryland General hospitals. The Johns Hopkins University and Hospital were heavy losers. The former had just about put its affairs into shape and had prepared the way for removal to its new site in the northern suburbs. It had a great deal of its funds invested in real estate in the burned district, including seven large buildings and warehouses. Of these five were burned to the ground, and it is not known exactly how fully insured the property was, but it will curtail considerably the income of the institution. One of the most serious losses, however, sustained by any institution was that of the Johns Hopkins Hospital. It is estimated that property belonging to it aggregating $1,300,000 was destroyed, and the loss of the annual rental therefrom will curtail the income at least one-third. This loss will continue until the property can be rebuilt and the rents resumed. As the hospital has been living up to the last cent of its income, the blow is a staggering one, and already there is talk of an appeal being made to the outside world for aid. Baltimore can do nothing at present. The office of the *Maryland Medical Journal* escaped, but its printing office was entirely destroyed with the tuberculosis issue (the February number), just in type. The number will be reprinted in Philadelphia, but it will be impossible to reproduce it entire. The office and fixtures of the State Board of Health, on South Street, were destroyed, with the greater part of the valuable library of the secretary, Dr. John S. Fulton, and the annual report of the board, which was in press. The records of the board were saved. The board has taken offices on North Avenue and Charles Street in the northern part of the city. One of the most singular facts connected with the fire was the absence of fatalities, there being but one death reported, that of a fireman from York, Pa., who was crushed under a falling wall. There were many injured, chiefly firemen, none fatally and few seriously. The fact that the fire occurred on Sunday only accounts partially for these results. Had it been a week day the rapidity with which it spread would have cost many lives. Several physicians lost valuable property in the burned district, which extended on either side of Baltimore Street from Liberty east to Jones' Falls, a distance of 11 squares and then southeast to the harbor. All that part of the city east of Light and South of Baltimore to the waters edge was burned. The fire extended beyond those areas here and there.

### MASSACHUSETTS.

**A Thousand a Day.**—In the first twelve days after the appeal for $50,000 was issued by the Springfield Hospital Corporation, more than $12,000 was subscribed.

**Paroled.**—Dr. Eugene Graves of East Boston, convicted of abortion and sentenced as a habitual criminal in 1892, has been released from the state penitentiary on parole.

**Unlawful Practice.**—T. J. Early, who posed as a physician in Lowell, and prescribed, has been tried, found guilty of unlawful practice and fined $200.——Ulric St. Pierre, of New Bedford, charged with practicing medicine without being lawfully authorized, was fined $100 and sentenced to imprisonment for three months.

**A Political Criticism Only.**—Drs. McGirr, physician to the diphtheria hospital, and Sennott, city bacteriologist, both of whom were so severely criticised in the recent city election in Cambridge, Mass., have been reappointed without opposition, although their critics were entirely successful at the polls. The criticism is said to have been for political effect.

**Report on Antitoxin.**—Dr. Samuel W. Abbot of the State Board of Health has summarized the work of the board in the production of diphtheria antitoxin as follows: *During the last four years 159,072 bottles of antitoxin have been produced and distributed free at a cost of $31,543, an average of 19.8 cents per bottle.* At retail prices this quantity would have cost the consumers $437,366. In 1900, when there were the greatest number of cases in the state, the average cost was only 13.6 cents per bottle.

**Departments Condensed.**—The bacteriologic and milk and vinegar departments of the Boston Board of Health, which are under the charge of Dr. Hilbert W. Hill and Dr. Charles Harrington, respectively, are to be brought together under one building. The change is made not to save money, for they do not duplicate each other's work, but for the convenience of the citizens. Forty culture stations report daily to the bacteriologist, while the other department analyzes each day samples of milk, vinegar and other foods.

**Personal.**—Dr. Walter J. Steeper, Westford, has been appointed medical examiner, vice Dr. Benjamin H. Hartwell, Ayer, deceased.——Dr. Marshall Calkins, after 38 years of service, has resigned from the medical staff of the Home for the Friendless, [illegible] Dr. Frederick B. Sweet is his successor.——Dr. [illegible] Lowell, has been made professor of ma[illegible] College of Physicians and Surgeons, Boston. Dr. Edward W. Brown has been elected city physician of Northampton, vice Dr. John S. Hitchcock, retired.

## NEW YORK.

**New Health Officers.**—Dr. Thomas H. Hallet has been made health officer of Clyde.——Dr. John H. Doughty has been appointed health officer of Fishkill.

**Osteopaths Try Again.**—Another effort is to be made by the osteopaths of the state to have a bill passed by the legislature which will legally recognize them. Two years ago a similar effort was made and failed.

**Smallpox.**—The epidemic of smallpox which has existed at Salamanca is now under control and quarantine will be raised. ——The condition of smallpox at Lockport is improving.——A number of new cases have been reported at Buffalo.

**Typhoid at Watertown.**—A typhoid fever epidemic is raging at Watertown. At the outset the disease was of a mild form, but has now assumed a more serious type. There are 400 cases in the city. The local authorities have been unable to trace the source of the disease, and the state health department will make an investigation. The city authorities have leased a large house which will be turned into a hospital. A filtration plant is being installed, but will not be ready before next fall. Filters have been ordered for all the schools.

**Deaths of 1903.**—Commissioner Lewis has made a tabulation of vital statistics for 1903, which shows that the total number of deaths reported for the year was 127,100, which makes a mortality per 1,000 of 16.7. While the total mortality is about 3,000 greater than that of the previous year the estimated increase in population makes the death rate lower. Smallpox caused 41 deaths, all but 16 occurring in and about Rochester. There were 1,250 deaths from pneumonia, and 7,960 from Bright's disease. Grip is estimated to have caused 8,000 deaths.

### Buffalo.

**Odd Fellows' Hospital.**—The new hospital donated by the Buffalo Odd Fellows and Rebekah lodges was dedicated at the State Odd Fellows' Home at Lockport.

**Medical Staff Elected.**—The medical staff of the Sisters of Charity Hospital elected officers as follows: *President*, Dr. James J. Mooney; *vice-president*, Dr. Charles S. Jewett, and *secretary*, Dr. Alfred E. Diehl.

**Personals.**—Drs. John Parmenter, D. W. Harrington and A. E. McCarthy have returned from the south.——Dr. Stephen Y. Howell has returned from Central America.——Dr. Henry D. Ingraham is recovering from an attack of pneumonia.——Dr. E. A. Southall, who was in the medical department of the Army, has returned to Buffalo after five years in the Philippines.

**General Hospital Report.**—President Clement, of the board of trustees of the Buffalo General Hospital has issued the annual report showing that during the past year contributions amounting to $165,242.50 have been received. The hospital has been in existence for 45 years, and has had many eminent men on its staff. Despite the many improvements which have been made the hospital is practically without debts. A new nurses' home is being constructed which will furnish accommodation for 66 nurses in individual rooms, and will have an assembly room, gymnasium, library, reception and lecture rooms.

### New York City.

**Much Pneumonia, Influenza and Measles.**—Since December 19 there have been 2,264 deaths from pneumonia in New York, and there are now more cases of serious influenza and measles reported there than at any time since 1891.

**Problems of Municipal Administration.**—Columbia University, in co-operation with the Academy of Political Science, has arranged for a series of nine free lectures on this subject, to begin February 26, and to be continued weekly. On April 15 former Health Commissioner Ernst Lederle will give an illustrated lecture on "The Health Department," and a week later John W. Brannan will talk on "Bellevue and Allied Hospitals."

**Large Deficits in Hospital Funds.**—A crisis has been reached in this city in the affairs of its great hospitals, and heavy deficits are said to be facing the majority of the big institutions. Some of them, it is declared, must inevitably succumb under their burdens of debt and close their doors. It is estimated that an endowment of $20,000,000 would be necessary to meet the combined deficits of New York's hospitals. This is due to the fact that many of the hospitals have been erected at far too great an expense, and resemble palaces and hotels rather than hospitals. The board of directors of the Eye and Ear Infirmary are considering the advisability and necessity of closing that institution. At the annual meeting of the board of managers of St. Luke's Hospital, held in October, they reported that the expenditures showed an excess over receipts of $32,161. The Lying-in Hospital faces a deficit of $88,477, and the Mount Sinai Hospital a deficit of probably $58,000. In 1902 the Presbyterian Hospital announced a deficit of $80,229. The Hospital for Ruptured and Crippled, $55,675, and the Post-Graduate Hospital in the same year showed an accumulated indebtedness of $44,103. Other hospitals showing deficits are Roosevelt Hospital, $9,208; J. Hood Wright Hospital, $524; Flower Hospital, $8,224; New York Infirmary for Women and Children, $6,678; German Hospital, $9,841, and the Orthopedic Hospital, $5,391.

## PENNSYLVANIA.

**Personal.**—Dr. John A. Morrison, who has practiced in Cochranville for sixty-seven years, celebrated his ninetieth birthday anniversary January 31.

**End of Butler Epidemic.**—The one-hundred and tenth death from typhoid fever at Butler occurred February 2. The State Board of Health has completed its investigations and the quarantine officer has returned to Pittsburg.

**Society Asks Incorporation.**—The application of the Berks County Medical Society for incorporation has been presented to court. The incorporators are Drs. Charles W. Bachman, Abraham S. Raudenbush, and John Y. Hoffman of Reading; Dr. Allison A. Stamm, Mohn's Store, and Dr. George Hetrich, Birdsboro.

### *Philadelphia.*

**Physicians Exonerated.**—Three physicians charged with failure to report cases of contagious disease had a hearing before the board of health, February 4, and were exonerated.

**Dinner and Reception to Physicians.**—Dr. Charles P. Noble gave a reception, February 4, to Drs. Thomas E. Cullen and Guy L. Hunner of Baltimore, at which there was an attendance of about 250. Prior to the reception, Dr. Noble entertained these gentlemen and six other guests at dinner.

**Deaths for the Week.**—Deaths from all causes for the week ended February 13 were 568, a decrease of 55 from the previous week. Of the new cases of contagious diseases there were of diphtheria, 58; scarlet fever, 104; smallpox, 58; typhoid fever, 103, a total of 23 more than for the previous week.

**Eddyite Child Dies.**—Although his wife begged him to call a physician for their infant child, ill with pneumonia, William Lake, an Eddyite, refused. The child died, and the father has been arrested, and two other Eddyites who were *particeps criminis* have been cited to appear before the coroner.

**Hospitals Allowed Bequests.**—In the recent adjudication of the estate of Henry C. Cochran a large sum was allowed as bequests to institutions. Following are some of the beneficiaries: Pennsylvania Hospital, $10,000; Presbyterian Hospital, and the University of Pennsylvania, $5,000 each; Gynecean Hospital, Polyclinic Hospital, Medico-Chirurgical Hospital, Home for Incurables and Sanitarium Association, $1,000 each; Northern Dispensary and Philadelphia Dispensary, $500 each.

**Lectures to Undergraduates.**—Dr. Frederick Holme Wiggin, New York City, at the invitation of the Montgomery Gynecological Society of Jefferson Medical College, delivered an address on "Some Practical Points in Abdominal Surgery, with Special Reference to a Simple Technic for Appendicectomy and Intestinal Anastomosis," before the student body of that institution on the occasion of the annual meeting of the society February 2. Later in the evening he was entertained at a dinner given at the Colonnade Hotel.

**Public Education in Hygiene.**—A campaign of public education on hygiene and especially on contagious diseases is being waged in Philadelphia. Dr. Alexander C. Abbott, president of the board of health, recently lectured in the Central High School to an audience of laymen on "The Prevention of Contagious Diseases." "Tuberculosis, Its Prevention and Cure" was the subject of a recent lecture, under the auspices of the Franklin Institute, by Dr. M. P. Ravenel, Bacteriologist of the State Live Stock Sanitary Board and Assistant Director of the Henry Phipps Institute. The Department of Public Health is to appeal to the legislature and to private charity to aid in conquering the great white plague. The registration of all consumptives is planned, and also the establishment of state camps at various points. The Pennsylvania Society for the Prevention of Tuberculosis will contend for the cleaning of the streets only between midnight and the early morning; the thorough wetting of the streets before cleaning, the heating of trolley cars in cold weather, the discarding of upholstered seats in street cars, and the enforcement of the anti-spitting ordinance. One of the lectures in the international course on tuberculosis, under the auspices of the Henry Phipps Institute, was delivered in Witherspoon Hall, February 15, by Dr. Herman M. Biggs, chief of the Department of Health, New York, on "Administrative Control of Tuberculosis."

**Inspectors Examined and Appointed.**—As a result of civil service examinations recently conducted for the city by Drs. John H. Musser, J. Chalmers Da Costa and Joseph McFarland, the board of civil service examiners for the health bureau, the following, out of some 200 applicants, were appointed as assistant medical inspectors, making the corps fifty in number: Drs. Maurice Ostheimer, Solomon W. Newmayer, Edmund L. Graf, Walter F. Brown, Harold B. Wood, Ignatius L. J. Fitzpatrick, Myer Solis-Cohen, Bernard Kohn, Walter B. Cornell, John Hedges, Joseph P. Ball, D. Cameron Bradley, Alva M. Stafford, W. Edson Apple, George M. Ferguson, Charles E. Ruffell, William P. Hearn, Joseph D. Leman, Charles C. W. Bartine, George J. Enders, Arthur Hartley, Walter W. Maires, Francois L. Hughes, Frederick W. Smith, James M. Hincken, Isaac V. Levi, George M. Coates, Michael O'Hara, Jr., Truman Auge, Sylvester J. Deehan, Morris J. Tyndall, W. Cookman Marshall, Andrew J. Maher, Henry G. Bruner, Louis N. Mutschler, Walter V. Wood, Victor Loeb, Ralph H. Spangler, Henry O. Everett, and Henry H. Doan. The corps was increased by councils from 13 to 50 members. Three of the former, Drs. Taylor, Cairns and Beatty were advanced to the positions, respectively, of chief vaccine physician, chief medical inspector, and assistant chief medical inspector. The salary of 'an assistant inspector is $1,200 a year.

## WISCONSIN.

**New Hospital.**—Dr. Frank H. Turner has constructed and equipped a hospital at Clam Falls, at a cost of about $7,000.

**Milwaukee Hospital.**—Nearly 1,000 patients were treated in the Milwaukee Hospital during 1903. At least one-third of these were indigent patients. The income of the institution exceeded the expenditure by $160.55.

**Not Yet Transferred.**—Information has been received that the notice in THE JOURNAL of February 6, that the headquarters of the State Board of Health had been moved to Madison, was premature. The transfer will not be made until April 1.

**Milwaukee Personals.**—Dr. George Koeppel, Jr., has resigned as house surgeon of Emergency Hospital, and sailed for Europe, February 11.——Dr. Albert G. Jenner, has been appointed medical referee for Wisconsin of the Mutual Life Insurance Company of New York.

## GENERAL.

**The Daily Medical.**—The first issue of the *Daily Medical* is before us. It contains medical news written up in newspaper style, with some pertinent editorials, all making a good representation for the field it was announced to cover.

**Queen's Hospital to Build.**—A brick addition, to cost $45,000, is authorized by the trustees of Queen's Hospital, Honolulu. The annual report shows that in 1903, 783 patients were treated, 44 died (6.14 per cent.), and 673 discharged. More patients were treated free than for pay. The institution received from pay patients $14,798, or $28,000 less than the current expenses. The withdrawal of the government subsidy may require a marked reduction in the amount of charity work.

**Sanitarians to Tour Mexico.**—Drs. George R. Tabor, state health officer of Texas; John H. Purnell of the Mississippi State Board of Health; C. P. Wertenbaker of the United States Public Health and Marine-Hospital Service, New Orleans; W. H. Sanders, state health officer of Alabama; Edward Souchon, president of the Louisiana Board of Health, and Arthur Nolte and W. G. Owen of the same board, and Dr. J. M. McKnight, local state health officer at Laredo, Texas, have been holding a conference in Mexico City with members of the Superior Board of Health of Mexico to devise means for preventing another yellow fever epidemic. They are also visiting Tampico, Linares, Victoria, Monterey, Vera Cruz and other cities along the coast of the Gulf of Mexico. After a thorough inspection of these cities, where yellow fever often originates, the commission hopes to formulate plans for a campaign of education and sanitation.

## CANADA.

**Report of Hotel Dieu Hospital, Montreal.**—During 1903 male patients admitted numbered 1,326; cured, 688; relieved, 504; incurable, 17; died, 117; females, 1,234; cured, 626; relieved, 493; incurable, 20; died, 95.

**Physicians and the New Ontario Assessment Act.**—The profession dislikes the proposal of the Ontario government to abolish the income tax and substitute a "business tax" irrespective of ordinary assessment, at the rate of 50 per cent. on the assessed value of property in which the physician resides. The change is considered too discriminating, and at a mass meeting of the profession at Toronto it was decided to protest. Such a tax, it is said, would make many practitioners pay ten times the amount they now pay in taxes.

**Consumption of Spirits, Wine and Beer in Canada.**—According to the last annual report of the inland revenue department at Ottawa, there were taken for consumption in Canada during the year ending June 30, 1903, 3,208.767 gallons of spirits and 25,755,154 gallons of malt liquor. The former is a slight increase over the previous year, but the latter is a decrease of 1,868,613 gallons. The annual consumption per head of spirits, wine and beer in Canada during 1902 was: Spirit gallons, .796; wine gallons, .090; beer gallons, 5.102; and in 1903, .870, .096 and 4.712. This shows a slight increase in the consumption of wine and spirits and a decrease in the consumption of beer.

## FOREIGN.

**The Sixth International Congress of Zoology.**—This will be held at Berne, Switzerland, Aug. 14-19, 1904.

**Eddyite Spreads Smallpox.**—Nine cases of smallpox were discovered in Edinburgh, the result of an Eddyite's going about among people while sick with the disease.

**New Journal for Anatomy and Microtechnic.**—Prof. R. Krause and Dr. M. Mosse of Berlin announce the foundation of a new *Centralblatt f. normale und pathologische Anatomie mit Einschluss der Mikrotechnik.*

**Russian Congresses of Surgery and Gynecology.**—The fourth annual congress of Russian surgeons was held at St. Petersburg, December 28. About 200 surgeons were in attendance. The next congress will be held at Moscow in December. The congress of gynecology was held at the same date.

**Epidemic of Ergotism.**—The Siberian district of Tomsk is suffering from an epidemic of ergot poisoning. The rainy weather of the last harvest season favored the growth of ergot in the grain, and in tests of 92 samples of flour only 10 were found free from appreciable amounts of ergot. Already 123 cases and 14 deaths have been reported.

**Prize for Work on Fatigue in Military Service.**—The Italian government offers a prize of $200 for the best article on the subject of "Fatigue in Military Life; the resistance of the organism and its factors; over-exertion and its consequences; the weight carried by the Italian soldier and measures to render it lighter and distribute it better without abandoning any essentials."

**Foreign Students at German Universities.**—The number of matriculated foreign students at the German universities is larger this year than ever before, amounting to 3,093, of whom 722 are in the medical schools. The proportion by nationalities of the medical students is not given in the report, but 310 Americans are included in the total number, and 133 from Asia, mostly Japanese.

**Meeting of Inner Council of International Antituberculosis League.**—The inner council has been summoned to meet at Copenhagen, May 27 and 28, to prepare for the international antituberculosis congress to be held at Paris in September, 1905. Among the subjects to be discussed are the reports of committees on the question of languages (Maragliano, chairman); antispitting ordinances (Hillièr); compulsory notification

(Fränkel); disposition (Schrötter), and education (Heron). The appointment of corresponding members will also be discussed, and the aims and scope of the international "Centralbureau" be more accurately defined.

**Director of Laboratory Dies from Plague.**—The laboratory for plague research at St. Petersburg is located on an isolated island near Fort Alexander. The director of the Institute for Experimental Medicine and the Production of Antiplague Serum was engaged at the laboratory with living plague cultures when he contracted the plague, January 26, and died in four days, notwithstanding repeated injections of antiplague serum. All the other persons connected with the laboratory were given preventive injections, but two new cases have developed. The entire establishment is strictly quarantined. The death of the director recalls those of Dr. Müller at Vienna and Dr. Sachs at Berlin, under similar circumstances.

**Inadequate Quarters for Science at Paris.**—Our Paris exchanges state that the new professorship which has been conferred on Curie has no laboratory connected with the chair, and the scientist and his wife had no place in which to continue their researches on radium. The Pasteur Institute has come to the rescue and Professor and Mme. Curie are now comfortably installed in a laboratory there. Prof. A. Robin has also recently been transferred from the Pitié to the Beaujon hospital. The latter has only one amphitheater, already occupied by Debove. Robin's lectures are, therefore, delivered in the sacristy to the little chapel, where his auditors find only two or three dozen chairs to seat the hundred or more present.

**International Institute of Bibliography.**—This unique institution was founded by Marcel Baudouin at Paris a few years ago. It is a collection of books, articles, bibliographies, illustrations, etc., kept on the plan of a card catalogue, and the collection on any subject or branch of a subject is loaned on demand to applicants. Abstracts or translations are furnished and all commissions to facilitate scientific research are executed by experts connected with the institute. The cards are loaned to any part of the world and the scientist remote from the centers of learning is thus able to have at his command what has been published on any subject in which he may be interested. The institute is to have an exhibit at St. Louis, and a branch office has just been opened at Madrid. The *Gazette Méd. de Paris* is the official organ of the institute, and the *Bibliographia Medica*, a successor to the *Index Medicus*, was published by Baudouin during 1900-1902.

**International Station on Mount Rosa for Physiologic Research.**—The international station in Switzerland, at an altitude of nearly 17,000 feet, was first visited by the Italians, Professors Mosso and Galeotti, C. Foa, A. Aggazzatti and G. Marro, with Professor Atwater from Middletown in this country. During a two weeks stay in 1902 various lines of physiologic research were industriously prosecuted. Last year Professor Zuntz of Berlin and Durig of Vienna with Mosso of Turin spent thirty days at the station. The report of the various tests and experiments is soon to be published with the title, "*Annali del laboratorio internazionale di fisiologia sul Monte Rosa.*" The station was a gift to science from the dowager queen of Italy, in 1901. Mosso regards as the most important result of the researches to date his observations on what he calls "acapnia," that is, the lessened proportion of carbonic acid in the blood at high altitudes.

**Prevention of Lay Publicity for Scientific Articles.**—Dr. H. Keller writes to the *Wiener klinische Rundschau* deprecating the publicity given in the lay press to Behring's new views. Such communications should be made before scientific bodies and the discussion kept from publicity until the matter has been fully weighed and the revolutionary statements made either established as truths or refuted. Behring's statements have been widely heralded all over Germany and the public informed that he regards the boiling of milk as distinctly injurious to infants. The impression made by his words on the public tends to throw discredit on the profession which has so persistently been advocating the boiling of milk. Keller merely cites this Behring episode as a typical example of what he thinks the profession should avoid. He urges that physicians should combine to avoid publicity for purely theoretical propositions, and prevent their publication in the political press. The editions of medical papers and articles should be copyrighted and each bear a notice to the effect that legal proceedings will be instituted against any one reproducing the articles without permission. He thinks this would effectually prevent the premature promulgation of views which conflict with all that has been learned by experience to date.

**The Sewage Farms at Paris and Their Influence on Health.**—The report for 1903 of the committee appointed by the Paris authorities to investigate this subject has just been published. The conclusions are to the effect that this method of purification of the sewage water by using it to fertilize the soil is surprisingly effectual. The water draining away from the sewage farms provides the drinking water for the communities nearby, and the vegetables grown are likewise consumed there in large amounts. Gennevilliers has about 2,400 acres of these sewage fields, with 138 acres cultivated as vegetable farms. With a population of 10,056 there were 202 deaths in 1902, not one of which was due to typhoid fever, diphtheria or intermittent fevers, and in the 18 deaths due to dysentery, 15 were of young infants and the others in children. The same is true of a town beyond, whose 2,243 inhabitants likewise drink the water draining away from the farms. Not a single case of infectious disease has occurred in either place which can possibly be ascribed to the use of the filtered sewage water. Paris has now 5,505 hectares, or about 13,700 acres of these sewage fields, and each acre receives about 180,000 cubic feet of water during the year. The sewage is first collected in large basins and the solid matters are filtered out and carried away by wagon or boatload, the water passing on to the sewage farms. Every year adds to the number of acres devoted to the purpose.

**United Action of the Profession in Germany.**—The troubles with the semi-official sickness insurance societies have solidified the profession in Germany to a remarkable extent since the introduction of the new law doubling the length of treatment of the policy holders. In Berlin a general meeting was held recently, with Prof. von Bergmann in the chair, which was attended by 1,500 physicians. It was summoned to protest against a certain measure required by the insurance societies. The protest was heeded by the societies and the obnoxious clause dropped. In Cologne all the medical officers of the principal society resigned, and the society was able to find only 30 physicians from outside willing to enter its service under the conditions prevailing. The government interfered and notified the local authorities that this number was inadequate for the 110,000 policy holders, and that at least 30 more fully qualified for the post must be engaged within three days. The local authorities, therefore, ordered the society to reinstate its former medical officers, conceding all their demands, "free choice," arbitration committee and the fee of 5 marks per capita and 15 marks per family, with agreement to the contract for a five-year term. The outside physicians were discharged with some compensation. Our exchanges hail this settlement of the trouble at Cologne as a great victory, rendered possible only by the united stand taken by the profession. In the ads published in the medical press warning against acceptance by outsiders of the posts left vacant by the resignations of the medical officers of the various "Kassen," it is stated that any one accepting such a post would be debarred thereafter from intercourse as a colleague with other members of the profession. In a very few places outsiders have come in and thus "stabbed the local physicians in the back" as our exchanges express it, but they are referred to as the "sweepings" of the medical profession. The resigning physicians are given financial aid by the *Leipziger Verband*, which now numbers many thousand members. Its aim is solely to promote the material welfare of members of the profession. There is a rumor to the effect that a reserve fund of $500,000 is being raised.

## DUBLIN LETTER.

### Midwives and Rotunda Hospital Nurses.

There is perhaps no hospital in the world whose name is so well known in every corner of Europe and America as the Rotunda Hospital, Dublin. Founded in the first half of the eighteenth century, it is the oldest lying-in hospital in the British islands, and is still by far the largest. It is very likely not so well equipped as many midwifery hospitals in America, and perhaps on the continent of Europe, but, so far as the home countries are concerned, it is admittedly in importance the premier hospital of its kind. In the face of all this it is hard to believe that nurses trained in the Rotunda and the other lying-in hospitals in Dublin are absolutely excluded from all practice in England by the new midwives' act. For many years medical men and others interested in health matters strongly urged the necessity of placing midwifery practice under proper regulation and control, as there was no check whatever on practice by very ignorant persons, and there was no register of midwives. As a result of this agitation in 1902 a bill was carried through parliament to provide for the proper control of midwifery practice. In this connection I may be pardoned for repeating an anecdote of Lord Salisbury's latest weeks in the house of lords. His habit of sleeping through all but the most important debates in the house was notorious, and he was known to nod even while the leader of the liberal party in the peers was on his feet. Shortly after his retirement he explained to a friend that he had latterly found the house intolerable, for whenever he wakened from a doze, he seemed to hear the Lord Chancelor talking about midwives. To return, however. The execution of the act was to be in the hands of a body known as the Central Midwives' Board, who, with the approval of the privy council, were to make regulations regarding the registration and discipline of midwives. This body, with all the importance of jack-in-office, immediately busied themselves in drawing up a code of rules of more than doubtful utility. Some of them certainly were excellent, but many of them were silly or unscientific, and have come in for much adverse criticism. It was not, however, until they came to draw up regulations guarding admission to the register that Irish nurses were particularly affected. There is to be a state examination passed before a midwife is permitted to practice, and candidates for such examination must show certain certificates. Among these are certificates stating that the nurse has personally conducted twenty cases of labor, and has attended for ten days after confinement in each case. Now a Rotunda nurse could truthfully claim that she had watched three or four hundred conductions, assisted at twenty or thirty, and personally conducted three or four; that she had watched six or eight hundred women during their puerperium, and personally nursed twenty or thirty, but she could not make the statements demanded by the board, for the usual period of detention of patients in lying-in hospitals in Dublin is eight days, and they would refuse to stay longer, nor would it be in their interests to do so. And with regard to allocating twenty conductions to each nurse, it would require, to quote Dr. Kidd, not merely doubling the size of our hospitals, but doubling our birth rate. Under the present conditions, while the "handy woman" of the English village is eligible to present herself for registration, the best-trained midwives in the kingdom are absolutely excluded. It is true that Irish obstetricians are themselves somewhat to blame, for, with the single exception of Dr. W. Smyly, not one of them raised his voice in protest until the objectionable rules were in force. The laxity of the Rotunda authorities in the matter is particularly blameworthy. At the opening meeting of the obstetrical section of the Royal Academy of Medicine in Ireland a few weeks ago the president brought the subject before the section, and very strong resolutions were passed demanding the repeal of the offending clauses.

### The Educational Situation in Ireland.

Before this letter is in print it will be known whether the government has any intention of introducing in the present session of parliament, a university bill for Ireland. That the existing position of affairs in regard to higher education in this country can not be much longer tolerated is obvious, for, whether the grounds of discontent are really sufficient or not, there is no doubt of the discontent being there, and outside Trinity College there is at the present moment no stable educational institution. A short history of university education in Ireland is necessary to make clear how we stand. Three hundred years ago a college was founded in Dublin, by name Trinity College, "to be the mother of a university." From that day to this, no other college has been established in Dublin University, and Dublin University and Trinity College are to all intents and purposes the same institution. For some two hundred years after its establishment, Roman Catholics were excluded from obtaining degrees in the university, but toward the end of the eighteenth century this disability was abolished, all posts of honor and emolument, however, being still preserved to members of the Established Church. It was not till 1873 that the last relic of official sectarianism was done away with by Fawcett's Act, and every prize and post from sizarship to provostship was thrown free to all comers, without any religious test. At the same time, however, no attempt was made to interfere with the conduct of the Church of Ireland Chapel, which still stands within the walls, nor was the Divinity School of the Church of Ireland disturbed. It was hoped that all religious tests having disappeared, Irishmen of every class would make full use of the university privileges thrown open to them, but this hope has been gravely disappointed. The number of Roman Catholic students entering the college has scarcely shown any increase, and of late years even tends to diminish. Three-fourths of the people of Ireland, but only one-tenth of the students of Trinity College, are Roman Catholics. Previous to Fawcett's Act, indeed, attempts had been made to provide university education for those who preferred not to make use of Trinity. In 1849 the Queen's University was set up by Sir Robert Peel, with three constituent colleges placed respectively in Cork, Belfast and Galway; the colleges were entirely undenominational, and provided no religious training. The Roman Catholic bishops at first favored the scheme, but soon came to regard it more coldly, and finally for some occult reason condemned the colleges, root and branch, as "godless." Nevertheless, in spite of many obstacles the Queen's University existed for some thirty years, doing very good work among those whose consciences permitted them to make use of it. In 1879, however, it was abolished, and the "Royal University" was established in its stead. This is a mere examining board, sitting in Dublin, and examining any candidate who presents himself. It matters not where he has been trained; he has, if he shows sufficient knowledge, a right to a university degree. The queen's colleges, which still exist, although the Queen's University was abolished, prepare many students for the Royal University, but many others are trained in various voluntary institutions. It is hardly to be wondered at that after twenty-five years' experience of this body, it has been shown to be an entire failure, as far as any true education is concerned, and this is the official judgment of a royal commission which has recently inquired into the matter. The position at present then is this—Trinity College or Dublin University, while open to every one, is refused by the bulk of the Roman Catholics of Ireland; the Royal University, an examining board, has been found useless; the Queen's Colleges, like Trinity College, are not made use of by Roman Catholics. Whether the position of the Roman Catholics in declining to avail themselves of Trinity College and the queen's colleges be logically justifiable or not, there is no question as regards practical politics that something must be done to satisfy their claim, and the only question is, what form should the solution of the difficulty take? I hope in a future letter to tell something of the schemes which are most prominently before the public at present.

## LONDON LETTER.

### The Disposal of Wounded Cavalry.

The need for some special form of light ambulance for mounted troops has for some time been recognized. In the *Journal of the United Service Institution* of India Lieut.-Col. Hathaway, medical officer with the cavalry divisional staff in the South African War, has published an important paper on the subject. Assuming that cavalry can not be allowed to look after their wounded, he suggests a scheme of mobile cart detachments. The detachment of each cart is to consist of five men, well instructed in first aid to the wounded. During peace a single cart and detachment should form the ambulance establishment of a regiment of cavalry; in war one cart would be required for every squadron. The cart should provide accommodation for as many wounded as possible, be light and yet strong, and able when empty to cross any country over which artillery can proceed. The cart considered by Colonel Hathaway most generally serviceable consists of a platform on strong springs over four wheels; the sides are padded and moveable so as to form back rests when the cart is used for sitting-up cases. The patients then sit on benches on each side of the cart, the stretchers being rolled up and placed under the seats. By an arrangement of hinged crossbars, which form a second or upper tier, the cart can be made to accommodate four patients lying down. There is also room for two patients who can sit up, in front. Thus in all six patients can be accommodated, and when the lower stretcher rests are used as seats, 10 patients. A double awning-cover supported on uprights from the center of the platform, allows stretchers to be loaded from each side without any obstruction from the sides. Thus any case can be attended to without removing the patient, a great advantage. The cart weighs less than nine hundredweight and appears to combine economy of space with comfort. Colonel Hathaway claims that, at little or no extra expense, these cars render mounted corps much more mobile in that they are relieved of attention to their wounded, who are removed rapidly by an organized body of men able on the march to maintain the pace set by the mounted unit. For men wounded on patrols where wheeled transport, however mobile, is impossible, he has invented a contrivance called a "saddle crutch" consisting of a semicircle of light metal padded inside and covered with leather which is used to support a wounded man after he is placed in his saddle.

### The Contamination of Shellfish by Sewage.

The Royal Commission on Sewage Disposal has issued another interim report containing a most important statement. During the various "oyster scares" it has been assumed that the presence of the *Bacillus coli* in the oyster is proof of sewage contamination. The commission have discredited this test. They ordered Dr. Houston to examine a large number of oysters from the purest beds, waters and from beds liable to pollution, in order to ascertain the distribution of the *Bacillus coli* in nature. Over 1,000 oysters were examined, with the result that the organism was found in nearly all, but as a rule much fewer bacilli were found in oysters taken from pure than from polluted water. The commission hopes that eventually it may be possible to establish a quantitative test. The importance of this pronouncement is obvious. The chief sanitary inspector of the City of London recently obtained an order for the destruction of oysters because they contained the *Bacillus coli*. The layings from which they came were consequently withdrawn from the market. But during the hearing of the case it was shown that great pains had been taken to keep the oysters free from pollution.

## Correspondence.

### The Anglo-American Medical Association.

Berlin, Feb. 3, 1904.

*To the Editor:*—The Anglo-American Medical Association of Berlin desires you to inform the profession of its organization and purposes. Realizing the difficulties which beset the path of the stranger the association places its services at the disposal of physicians who intend to study in Berlin. Such are cordially invited to attend the meetings which are held weekly, and any information concerning the work to be had here will be gladly given to any member of the profession who will communicate, on his arrival in Berlin, with Dr. J. H. Honan, president, Lützen Strasse 78, or with the undersigned committee.

Albert J. Mayer, M.D., Secretary.
David Shannon, M.B.
Wm. W. Graves, M.D.

Albrecht Strasse 22.

Note.—Further particulars of this association were given in The Journal Jan. 30, 1904, p. 320.—Ed.

### Susceptibility to Disease.

Goddard, Kans., Jan. 14, 1904.

*To the Editor:*—I desire to call the attention of the profession to an important factor in the estimation of susceptibility to disease as influenced by age, namely, the decrease in the number of persons living as age increases. I have not been able to learn by a search of such literature as is available to me, and by a correspondence with several men of wide knowledge that this fact has ever been considered in the construction of tables intended to illustrate the varying susceptibility to a given disease at different ages.

The tables or reports, as constructed, doubtless illustrate truly the prevalence of the disease at different ages, but fail signally in showing the varying susceptibility. Thus, a compilation before me shows that out of 434 cases of pneumonia, 42 occurred between the ages of 10 and 20, and 24 occurred in persons from 60 to 70 years of age. This statement alone indicates a greater liability to the disease at the earlier age than at the later. Let us apply to the statement the American table of mortality and observe the result. This table begins with 10 years of age, and assumes the death of all persons at 96; and is on the whole probably the nearest approach to actual experience in the United States that has been as yet compiled. Out of 100,000 persons at age ten, 99,251 are living at eleven, 98,505 at twelve, and 92,637 at twenty. At the age sixty-one, 56,371 and at age of seventy, 38,569 are living. Assuming that the compiler of the cases of pneumonia meant by the phrase "between 10 and 20 years" from 11 to 20, inclusive, we find the average number living in that decade, out of the original 100,000, to be 95,928, while for the decade 61 to 70, inclusive, there are living an average of 47,996; barely half as many. The ratio of liability, therefore, instead of being 42 to 24, is, if we take the number living in the first period as the basis of comparison, 42 to 24, multiplied by a fraction of which 95,928 is the numerator, and 47,996 the denominator; that is, 42 to 48—a marked difference.

In the computation of relative mortality, the difference is still more striking. Thus, Osler, in considering the etiology of pneumonia, quotes under the head of age from the census of 1890, that for every 100,000 of population there were between the ages of 15 and 45 years, 100.05 deaths; between 45 and 65, 263.12, and for 65 years and over, 733.77. Reducing this to a percentage, we have for the first period 9.1 per cent.; for the second, 24 per cent., and for the third period, 66.9 per cent.

Assuming that the author meant 15 to 44, inclusive, and 45 to 64, inclusive, for the first and second periods, we find the average number living in those periods to be, of the 100,000 living at 10 years of age, 85,751 and 64,242, respectively, while the average for the period of 65 to 95, inclusive, or the end of the table is 18,458. Assuming the average number living during the first period as the basis of comparison, we find the relative mortality to be, not 100.05 to 263.12, but 100.05 to 263.12 multiplied by a fraction, of which 85,751 is the numerator and 64,242 is the denominator; that is, 100.05 to 351.22. And a like calculation for the third period would show a relative mortality of the enormous number of 3,409. Reducing these numbers to percentages, we find for the first period a relative mortality of 2.6 per cent.; for the second, 9.1 per cent., and for the third, 88.3 per cent. While a comparison of deaths alone for the first and third periods shows a ratio of 1: 7.32, a consideration of the numbers of people living in the respective periods points to a real mortality ratio of 1 to 34.

It is hardly to be expected that many diseases will show such a striking difference in mortality at various ages as pneumonia; but only a careful investigation will determine, and the subject is worthy of such investigation.

In this study, other factors ought to be considered as immunity from a disease at a later age by reason of an attack at an earlier age. Thus, measles in this country is almost exclusively a disease of childhood, because of the well-nigh universal exposure at that time of life, and the consequent immunity, with rare exceptions, for the remainder of life. That it may attack individuals at all ages we know; and the universal predisposition to the disease at all ages, when not protected by an attack early in life, is well illustrated by the epidemic which raged a few years ago on the introduction of the disease into the Fiji Islands.

It will not be easy to eliminate this disturbing factor, though attention being directed to it in this connection, a long course of careful observation will do much toward that end. It will be easier to eliminate the effect of those diseases which, as pneumonia, leaves the patient, after a short immunity, with impaired powers of resistance to further infection. All that we have to do in that case is to exclude attacks subsequent to the first. The instances of second and later attacks of those diseases, one attack of which almost universally grants a life immunity, are so rare as to be perhaps negligible.

Notwithstanding the difficulty and perhaps the impossibility of getting ideal results, by reason of the obstacles alluded to, the investigation ought to be made in the interest of greater accuracy; and I venture to suggest a way of making it. Let a large number of the best hospitals in all portions of the United States be requested to send transcripts of their records bearing on this subject to some central office for compilation and calculation. Only in this way, it would appear, can a sufficient number of cases at all ages be had to give fairly accurate results.

This calculation ought to be made for each year of life. While I have never seen a table of infant mortality, the fact that a number of life-insurance companies take risks on children, points to the existence of such a table; and the short time involved, from birth to the tenth or the fifteenth year, ought to give assurance that the compilers have attained to at least as great a degree of accuracy as is found in the tables for older ages.

A combination of the tables of mortality of infancy and childhood could then be made with the American or some other standard table, as the combined experience, and the calculation for all ages, from birth to 96 if the American be used, or 100 if the combined experience be selected, can be made. By such a combination we should be enabled to use the initial number at birth as a basis or unit of comparison for all ages, just as in the standard tables we can use the initial number 100,000 at age 10 as a basis of comparison for all subsequent ages.

It is in the hope that some one with the authority of a great medical organization behind him and to whom vast numbers of histories are, or may be made acceptable, may take up this work, that I have ventured to make the above suggestions.

W. H. Graves, M.D.

# Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

## CONGLUTINATION OF THE EXTERNAL OS AFTER AMPUTATION OF THE CERVIX.

San Francisco, Feb. 1, 1904.

*To the Editor:*—The effect of amputation of the cervix on labor has, as far as I can ascertain, received but scant recognition; in fact, one of our most distinguished gynecologists dismisses the subject by saying: "Amputation of the cervix does not interfere with conception, pregnancy or labor." That with a preceding atresia conception could not take place needs no discussion, but that atresia can take place after conception, and interfere greatly with labor, the following case will illustrate. In May, 1903, it became absolutely necessary to amputate the cervix of a bipara, aged 26. She stated that menstruation had ceased a week previously. I did not curette the uterine cavity, being sceptical as to her veracity. Subsequent events proved my doubt to have been well founded. Three months after the operation, there being no recurrence at menstruation, she came for advice, and an examination showed a pregnancy of about four months, which continued without deviation, following the usual course. January 14 I was sent for, found patient in labor, the presenting part having entered the superior strait, covered by the upper vaginal wall, like a cap, but neither by the eye, through a speculum nor by the sense of touch, could the slightest opening be detected. The pains suddenly ceased for a week, then began with renewed vigor, keeping up for two days, the position of the fetus remaining exactly the same, with not the slightest sign of dilation. Further delay being dangerous, I called Dr. Frank Gray in consultation; we concluded that if an entrance could not be effected through the vagina, cesarean section and a possible Porro operation were strongly indicated. I admit the latter did not appeal to me, both on account of the danger from shock and the age of the patient. She was removed to Lane Hospital, and after twenty minutes' probing with the finger, I felt a sunken spot, bored through and entered the cavity through the internal os, which was dilated to the size of a dollar. I continued manual dilation and found a breech, that had just about entered the pelvic cavity, applied forceps and extracted babe in a condition of asphyxia livida. Twenty minutes of artificial respiration insufflation, etc., restored the child. The patient made an uninterrupted recovery, the temperature never reaching above 99.8. At present both mother and child are doing well. Had the patient menstruated within the usual time after the cervical operation the probabilities are that no atresia of the canal would have taken place, as no such result followed a number of previous similar operations. Now the question arises, will the os remain patent? I can not evolve a satisfactory answer, for possibly the next six months, but in the meantime will keep the patient under observation, using the probe from time to time.

William Himmelsbach, M.D.

Answer.—Occlusion of the external os is a well-recognized although somewhat rare cause of dystocia. It may occur in primiparæ who have never undergone local treatment when it is generally due to persistence of a "pinhole" os. In multiparæ or in primiparæ who have had treatment, it is generally due to traumatic adhesions that may follow injuries of labor or caustic applications or operations like amputations of the cervix. Cases of occlusion of the external os due to amputation have been reported, but not frequently, and the above case is worth recording. In the diagnosis of this condition the possibility of the displacement of the cervix to one side, backward or even above the promontory, must be kept in mind. When the diagnosis is made, the minute opening which marks the external os or the depression which marks where it should be, is carefully sought for by the examining finger, and if found, an opening made by the simple maneuver adopted by our correspondent. When the site of the external orifice can not be determined by palpation the patient should be put in a good light, under anesthesia if necessary, and the walls of the vagina well retracted to allow a thorough inspection of its fornix. In this way the orifice or the location where it should be may generally be found and dilatation begun by stretching or cutting. In these rare cases in which the original location of the os can not be determined it may be necessary to make a crucial incision that may need extension to admit the immediate delivery if the case is urgent. We are not aware that agglutination has occurred repeatedly in the same patient, but it would certainly be desirable to keep such a patient under observation, both before and after the occurrence of a subsequent pregnancy. Incidentally we suggest that the practice of applying forceps to the breech is not to be commended. Pushing up the breech and bringing down a leg is certainly a safer and more reasonable procedure.

## FIRST AID INSTRUCTION TO PUBLIC SCHOOL SCHOLARS

Drachm, Salt Lake City, writes: A western physician has a 14-year-old boy who recently showed that he was not alone possessed of good sound horse sense and proper surgical instinct, but is a good booster for his father. While playing with a crowd of boys one little chap ran a rusty nail into the sole of his foot. The doctor's boy, immediately carried him into a nearby house, where, in spite of his patient's tears and protestations, he first removed the shoe and stocking, and after washing the foot carefully with hot water, carried him several blocks on his back to his father's office, where the wound was disinfected and dressed. The incident suggests the good that might be accomplished, or rather the harm that might be prevented, by a little instruction along these lines to the older pupils in the public schools.

## HERNIOPLASTY.

Dr. Hermann B. Gessner, New Orleans, writes to suggest the use of the word "hernioplasty" to replace the expression "radical cure operation for hernia." The reasons for the substitution are, he believes, obvious.

# Marriages.

Edward B. Hodge, Jr., M.D., to Miss Mary G. C. Greene, both of Philadelphia, February 10.

Thaddeus Cothern, M.D., Walcott, Ark., to Miss Anna Hutchins of Finch, Ark., January 24.

Theodore H. Page, M.D., Gold Hill, Colo., to Miss Mathilda Heidrich of Peoria, Ill., February 9.

Andrew Clifton Hansen, M.D., Fulton, Ill., to Miss Stella L. Griffin of Peoria, Ill., December 31.

James A. Turner, M.D., High Point, N. C., to Miss Fannie M. Little of Charlotte, N. C., February 4.

Ernest F. Robinson, M.D., Kansas City, Mo., to Miss Mary Kip of San Francisco, at Omaha, February 6.

J. Miller Byrne, M.D., Waynesboro, Ga., to Miss Mary Willie Heggie of Grovetown, Ga., February 24.

John Duncan Emmet, M.D., New York City, to Miss Josephine Wharton Drexel of Philadelphia, February 9.

# Deaths.

**Virgil O. Hardon**, M.D. Bellevue Hospital Medical College, New York, 1874, professor of obstetrics and diseases of women and children in the Atlanta College of Physicians and Surgeons, died at his home in Atlanta, Ga., from pneumonia complicated by organic heart disease, February 7, after an illness of ten days, aged 54. The active and honorary pallbearers were members of the faculty of the college, and the Atlanta Academy of Medicine furnished an honorary escort of its members.

**John Eggleston Byers**, M.D. New York University, 1879, for twenty years surgeon of the Pennsylvania Railroad at Butler, Pa.; a member of the National Association of Railway Surgeons, the Medical Society of the State of Pennsylvania, and recently president of the Butler County Medical Society, died suddenly from cerebral hemorrhage, February 8, aged 49. His death is attributed to overwork as county physician during the recent epidemic of typhoid fever.

**Jacob Repelye Ludlow**, M.D. University of Pennsylvania, Philadelphia, 1845, lieutenant-colonel in the medical department during the Civil War; first president and a life-long member of the Easton Medical Society, died from pneumonia at his home in Easton, Pa., February 10, aged 79. He retired from practice five years ago.

**Henry Lyle Smith**, M.D. College of Physicians and Surgeons, New York, 1864, a member of the New York State Medical Association, the New York State and Columbia County societies, and of the Society of the Alumni of Bellevue Hospital, New York, died, February 11, at his home in Hudson, N. Y., aged 60.

**John W. Jones**, M.D. University of Pennsylvania, Philadelphia, 1857, for many years a member of the State Board of Health, and once president of the Medical Society of the State of North Carolina, died at his home in Tarboro, N. C., January 28, from paralysis, after an illness of a few hours, aged 72.

**Edward C. Runge**, M.D. Washington University, St. Louis, 1891, up to February 1, superintendent of the St. Louis Insane Asylum, died at his home in St. Louis, February 10, from pneumonia, following influenza, after an illness of one week, aged 50.

**Edward Howard Moore**, M.D. Starling Medical College, Columbus, 1903, chief assistant at the Lawrence Hospital for Women, Columbus, died at the hospital, February 6, from cerebral meningitis, after a short illness, aged 28.

**Joseph G. Rooney**, M.D. New York University, 1891, of West Hoboken, N. J., died February 4, from gangrene following frost-bite of the hands, January 18, when he attended a number of firemen who had been injured.

**M. Luther Goodlett**, M.D. Medical College of the State of South Carolina, Charleston, 1861, surgeon in charge of Winder Hospital, Richmond, during the Civil War, died at his home in Tupelo, Miss., February 5, aged 69.

**Howard Jackson Seeley**, M.D. Long Island College Hospital, Brooklyn, 1899, professor of histology in that institution, a resident of Brooklyn, died at Asheville, N. C., from pneumonia, February 7, after a brief illness.

**Joseph B. Roe**, M.D. University of Pennsylvania, Philadelphia, 1861, surgeon for four years during the Civil War, and state senator in 1889 and 1890, died at his home in Woodbury, N. J., February 4, aged 68.

**John R. Hinkson**, M.D. Bellevue Hospital Medical College, New York, 1889, died at his home in Blissville, Long Island City, February 5, from pneumonia, after an illness of one day, aged 48.

**Frederick Corfe**, M.D., surgeon in the British service and also in the Civil War, died suddenly from heart disease while responding to a toast at a banquet in Union, Iowa, January 29, aged 69.

**Nicholas M. Edwards**, M.D. University of Pennsylvania, Philadelphia, 1860, died at his home in Slater, Mo., February 8, from paralysis following a fall four days before, aged 66.

**Daniel Francis Murphy**, M.D. Harvard University Medical School, Boston, 1887, died from pneumonia at his home in Woburn, Mass., January 30, after a short illness, aged 44.

**Charles Edward Manierre**, M.D. Chicago Medical College, 1882, of Chicago, a member of the American Medical Association, died at Oconomowoc, Wis., February 8, aged 43.

**Richard McDermott**, M.D. Starling Medical College, Columbus, 1882, died at his home in Thompsonville, Mich., February 4, from gallstone disease, after a long illness, aged 53.

**John Mercer Adler**, M.D., of Devon, Pa., chief surgeon of the military hospital at Davenport, Iowa, in the Civil War, died at his home, February 13, from apoplexy, aged 76.

**Christopher B. Naudain**, M.D. Pennsylvania Medical College, Philadelphia, 1856, was found dead at his home in Wilmington, Del., from heart disease, February 1, aged 67.

**Charles H. St. John**, M.D. Kansas City (Mo.) Homeopathic Medical College, 1896, died at his home in Salina, Kan., February 5, after an illness of several weeks.

**Oscar Everett Carter**, M.D. University of Vermont, Burlington, 1884, died suddenly at his home in St. Johnsbury, Vt., from heart disease, January 29, aged 44.

**Theodore F. Stark**, M.D. Jefferson Medical College, Philadelphia, 1877. died at his home in Minneapolis, Minn., January 30.

**Charles Frank Keys**, M.D. New York University, 1891, died at his home in Keyser, W. Va., February 4, from pneumonia, after an illness of three weeks, aged 35.

**Henry Bigelow Allen**, M.D. Bellevue Hospital Medical College, 1866, died at his home in Baldwinsville, N. Y., January 30, after an illness of six years, aged 60.

**J. L. Roll**, M.D. Louisville Medical College, 1881, died at his home near Wilderville, Texas, from consumption, after an illness of several months, January 30.

**Elias Vernon**, M.D. Jefferson Medical College, Philadelphia, 1851, died at his home in Hamilton, Ont., February 6, after a long period of invalidism, aged 76.

**Frank Gaylord Eastman**, M.D. College of Physicians and Surgeons, New York, 1890, died at his home in East Greenwich, Conn., February 8, aged 37.

**John R. Anderson**, M.D. University of Nashville, 1859, died at the home of Dr. John W. Nuckolls, Toone, Tenn., February 8, after a long illness, aged 72.

**Luther B. Hunley**, M.D. University of Maryland School of Medicine, Baltimore, 1877, died at his home in Mathews, Va., February 4, from pneumonia.

**Ashbel R. Otis**, M.D. Jefferson Medical College, 1867, died from pneumonia at his home in Dundee, N. Y., February 5, after a short illness, aged 62.

**Bernard J. Carr**, M.D. College of Physicians and Surgeons, Baltimore, 1895, died at his home in Beloit, Wis., from typhoid fever, February 8, aged 35.

**Charles S. Pugsley**, M.D. University of Buffalo, 1870, died in Olean, N. Y., from Bright's disease, after a long illness, January 30, aged 59.

**Charles W. Dodd**, M.D. University of Michigan, Ann Arbor, 1884, died suddenly from apoplexy, at his home in Cincinnati, February 7, aged 44.

**Enoch F. Bradford**, M.D. Harvard University Medical School, Boston, 1869, died at his home in Mechanic Falls, Me., February 8, aged 69.

**Edward Silverberg**, M.D. University of Louisville, 1855, of Knobel, Ark., died at St. Vincent's Infirmary, Little Rock, February 9.

**Enoch Q. Marston**, M.D. Harvard University Medical School, Boston, 1876, died at his home in Center Sandwich, N. H., February 1.

**William H. Jones**, M.D. Medical College of Ohio, Cincinnati, 1869, died suddenly at his home in Henry, Ill., February 9, aged 60.

**James H. Fleming**, M.D. Missouri, 1866, died at his home in Joplin, Mo., February 3, from paralysis, after a brief illness, aged 71.

**Henry Cornell**, M.D. University of Vermont, Burlington, 1854, died suddenly at his home in Hillsdale, N. Y., January 24, aged 84.

**William L. Robinson**, M.D. Eclectic Medical Institute, Cincinnati, 1886, of Milton Center, Ohio, died recently in Toledo, aged 42.

**William D. Wade**, M.D. Eclectic Medical Institute, Cincinnati, 1870, died at his home in Plymouth, Ill., February 8, aged 62.

**Ida E. Mushett**, M.D. Eclectic Medical Institute, Cincinnati, 1879, died at her home in Napa, Cal., February 2, after a short illness.

**John A. Groff**, M.D. University of Pennsylvania, Philadelphia, died at his home in Reading, Pa., February 4, aged 59.

**P. P. Gray**, M.D. Hahnemann Medical College, Chicago, 1880, died at his home in Ellensburg, Wash., February 7, aged 60.

**Ora E. Marvin**. M.D., of Springfield, Mass., died suddenly from apoplexy, at Westfield, Mass., February 1, aged 56.

**Thomas Mullin**, M.D. Ohio, died suddenly from heart disease at his home in Marietta, Ohio, February 6, aged 48.

**Henry W. Hill**, M.D. New York University, 1849, died at the home of his son in Rome, Ga., February 6, aged 70.

**David D. Ross**, M.D. Eclectic Medical Institute, Cincinnati, 1863, died at his home in Peoria, Ill., recently.

**Joseph Hoffmeister**, M.D., died at his home in Rutledge, Tenn., February 8, aged 78.

**J. H. Wood**, M.D., died at the home of his son in Emporia, Va., February 8, aged 85.

**Emil Barringer**, M.D., died at his home in Watervliet, Mich., February 4, aged 58.

# Miscellany.

**Otero's Method of Demonstrating the Malaria Parasite.**—M. Otero of Mexico writes to the *Gaceta Medica* of March 15, 1903, that at the high altitude of the city of Mexico the barometric pressure is much less than at the altitudes where Laveran made his experiments with the malaria parasite. Consequently the hematozoa retain their motility longer. The corpuscles in the blood become disintegrated long before the parasites lose their motility. By waiting six to nine or even twenty-four hours the hematozoa are still lively while the corpuscles are destroyed. They are thus easily differentiated without the necessity for staining, which impairs the vitality of micro-organisms.

**The Bureau of Standards.**—This bureau, which was transferred to the Department of Commerce and Labor last year, tests and standardizes all weights and measures. This includes the testing of clinical thermometers to secure a uniform scale of temperature. According to the bulletin just received, when the work of this bureau began, considerable variation was found in thermometers; as a result of the corrections given, thermometers now submitted by different manufacturers vary from the international standard only very minutely. Attention is called in this bulletin to the fact that thermometers not made of hard glass change their indications slightly by seasoning. After six months the indications are practically permanent.

**Contract Practice.**—The Norfolk (Va.) Medical Society recently took up the subject of contract practice and adopted certain rules governing it. Individual or family contracts are prohibited by that society. Governmental contracts are allowable as in the past. In regard to corporations, it was decided that the employment of a surgeon to care for men injured while in the employ of the company, is allowable, providing it does not prevent the patient from having free choice in the selection of the physician, but the society "would prefer that the surgeon be paid for actual work done and not a yearly salary." Any underbidding for insurance fees is considered not consistent with membership in the society. Club practice, which is defined as a branch of contract practice which furnishes medical attention to members through an organization or club, is prohibited. It was decided that "this class of practice injures the profession as a whole financially; that it lowers the dignity of the profession by putting the men who do this work at the mercy of promoters, and that it is of great injury to the members of the medical fraternity."

**Homeopathy Given a Chance in the Leyden Medical Faculty.**—The chair of pathology and therapeutics at the University of Leyden, Holland, has been vacant since the retirement of Professor Rosenstein who reached the age limit nearly a year ago. When the government indicated its intention of calling a homeopath to the chair, the medical faculty protested. One member of the faculty, Professor Straub, editor of the local medical journal, did not agree with his confrères, and approved of the plan, stating that he would like to see a homeopath in the chair and a well-equipped hospital placed in his charge in order to give homeopathy once for all a chance to show what it could accomplish. If it could show better results than were attained in the other clinics and hospitals, the profession would gladly recognize it. The matter was discussed pro and con for a long time in the lay press, and the recommendations of Professor Straub were finally adopted and further opposition abandoned. The minister then appointed two homeopaths to select a suitable candidate to fill the chair worthily, the only restriction being that he must not be a Hollander, as local professional clashing was feared. The nominating committee traveled far afield, and among others sought the credentials of a "Dr." Mende-Ernst, an ex-parson homeopath charlatan in Switzerland. The latter at once advertised abroad that he had been offered the chair and had accepted it, and this item went the rounds of the medical press. But it was untrue, as the committee dropped him at once from its list so soon as his reputation was known. The results of their search, embodied in their report, are to the effect that they were absolutely unable to find a homeopath with sufficient educational acquirements for a professorship in a university. Consequently a young physician, a Hollander, Dr. P. Ruitenga, has been called to the chair which was the scene of Stokvis' labors, and he entered on his duties with the new year. The *Wiener klinische Rundschau* of January 17 publishes a letter from Amsterdam in which the writer comments on the above facts and says that the homeopaths can never more make their old complaint that they are never given a chance.

**Diet.**—The *Medical Sentinel* condemns the diet craze, and suggests that the profession, instead of passively allowing patients to putter with some of the hundreds of patent breakfast foods, should turn their attention away from morbid self-dieting. The concentrated nourishment theory is a myth, and it is recommended that patients be allowed to eat these alleged foods only on the proviso that they eat breakfast first. The editor says that one egg or two small rashers of bacon contain more actual nourishment than a soup dish full of the flaky delusions. This may be true, but we doubt the advisability of recommending eggs or bacon, as they are ordinarily fried, as food for dyspeptics. The editor hits the nail on the head in the following words: "The conviction is steadily growing in the profession that disturbances of digestion, let alone other diseases, are due in eight cases out of ten, not so much to the food used, either in quantity, quality, or method of cooking, as to the circumstances under which it is eaten; the disgraceful hurry and rush with which business or pleasure is resumed before the digestion has had time to get fairly under way, and the utter lack of an adequate amount of exercise in the open air to enable proper combustion of the food. Further than that we are reacting decidedly from the exclusive and rigid diet for almost any condition whatever, with the partial exception of diabetes. Even where these exclusive diets may relieve the symptoms which they are designed especially to meet, they are very apt to upset the general balance of nutrition and impair the vitality, frequently in the long run aggravating even the symptoms, or the disease, which they were prescribed to cure." On the same subject is an article in *The World's Work* (February) on "Perfect Feeding of the Human Body," which is only a description of how one man, Mr. Horace Fletcher, having been refused life insurance on the ground of stomach trouble, corrected his habits and vastly improved his health. He does not diet in the ordinary understanding of the word. He eats everything, but in very small quantities. He has a rule to take thirty chews on each portion of food he places in his mouth. He says that the longer he chews the better it tastes. He now eats one-third or one-quarter what he formerly ate. He can do physical exertion equal to an athlete in training without fatigue, and finds less sleep necessary. This is not a new theory, but it is all right. Morbid introspection is the bane of the dyspeptic. An abundance of time to eat, a thorough mastication and cheerful surroundings are better than all the diet lists and breakfast foods that have ever been prepared.

# State Boards of Registration.

## COMING EXAMINATIONS.

Regent of the State Board of Medical Examiners of New Hampshire, State House, Concord, March 1-2. Regent, Channing Folsom, M.D., Concord.

Board of Registration in Medicine for Massachusetts, State House, Boston, March 8-9. Secretary, Edwin B. Harvey, M.D., State House, Boston.

Committees of Examination of Connecticut, New Haven, Hartford and Waterbury, March 8. Secretary, Prof. C. A. Lindsly, New Haven.

Maine Board of Registration of Medicine, Portland, March 23. Secretary, A. K. P. Meserve, M.D., Portland.

Regular Board of Medical Examiners for Georgia, *Atlanta*, March 30. Secretary, I. H. Goss, M.D., Athens.

---

**North Dakota Report.**—Dr. H. M. Wheeler, Grand Forks, secretary of the North Dakota State Board of Medical Examiners, reports that 16 applicants passed, out of 18 who took the written examination in January at Grand Forks. The percentage required was 75. The colleges, grades and years of graduation are below.

PASSED.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| | (1903) | 76, 76, 78 |
| Milwaukee Medical College | (1903) | 85, 86 |
| Northwestern University, Chicago | | 87 |
| University of Minnesota | (1900) 80, (1901) | 87 |
| Royal University of Norway | (1891) | 82 |
| University of the City of New York | (1889) | 78 |
| University of Iowa, Hom. Dept | (1898) | 75 |
| University of Illinois | (1903) | 75 |
| Hamline University | (1901) | 87 |
| [illegible]a, Norway | (1897) | 82 |
| [illegible] | (1903) | 82 |
| [illegible] | (1903) | 76 |
| University of Western Canada | (1902) | 82 |

Those rejected were graduates of Bennett Medical college, 1895, and Milwaukee Medical College, 1902.

South Dakota Report.—Dr. H. E. McNutt, Aberdeen, secretary of the South Dakota Board of Medical Examiners, reports the written examination held at Sioux Falls, Jan. 13 and 14, 1904, as follows: Subjects, 10; questions, 80; percentage required, 75; total applicants, 24; passed, 17; failed, 4; withdrew, 3.

| College. | Year Grad. | Per Cent. |
|---|---|---|
| Northwestern University, Chicago | (1900) 86, (1903) | 79, 86 |
| Rush Medical College, Chicago | (1880) | 89 |
| College Physicians and Surgeons, New York | (1891) | 84 |
| Milwaukee Medical College | (1902) | 82 |
| Beaumont Hospital Medical College | (1897) | 83 |
| Hamline University | (1903) | 85 |
| Woman's Medical College of Pennsylvania | (1903) | 93 |
| Yale University | (1902) | 81 |
| Saginaw Valley (Michigan) Medical College | (1902) | 78 |
| Sioux City College of Medicine | (1897) | 88 |
| Michigan University | (1902) | 87 |
| Alabama Medical College | (1884) | 75 |
| University of Christiania, Norway | (1891) | 90 |
| Harvey Medical College, Chicago | (1903) | 87 |
| Bennett Medical College, Chicago | (1900) | 82 |

Those who failed were graduates of the following colleges: University of Iowa, 1897; Hamline University, 1903; College of Physicians and Surgeons, St. Louis, 1898; New York University Medical College, 1890. Those who withdrew were graduates of Sioux City College of Medicine, 1903; Baltimore University, 1887, and University of Vermont, 1889. Three others who were unfitted left the state without attempting the examination, although they had applied and paid the fee.

# The Public Service.

## Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ending Feb. 13, 1904:

Hess, Louis T., and Collins, C. C., asst.-surgeons, promoted captain and asst.-surgeon, U. S. Army, to rank from Jan. 30, 1904.

Webb, Walter D., asst.-surgeon, promoted captain and asst.-surgeon, U. S. Army, to rank from Feb. 10, 1904.

Graves, Leonard K., contract surgeon, ordered to proceed from New York City to Fort Douglas, Utah, and accompany the Twelfth Infantry to service in the Philippines.

Ferguson James B., contract surgeon, ordered from Boise Barracks, Idaho, to duty as transport surgeon of the *Dix*.

Tukey, William H., contract surgeon, at present transport surgeon of the *Dix*, ordered to proceed when relieved to Boise Barracks, Idaho, for duty.

Tignor, Edwin P., contract dental surgeon, ordered from Jefferson Barracks, Mo., to temporary duty at Fort Crook, Neb., on the completion of which he will return to his proper station, Fort Riley, Kan.

## Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Feb. 13, 1904:

Stuart, A., asst.-surgeon, detached from the naval hospital, Naval Home, Philadelphia, Pa., and ordered to the *Marietta*.

Brister, J. M., asst.-surgeon, ordered to the naval hospital, Naval Home, Philadelphia.

Wheeler, W. M., surgeon, detached from the *Nipsic* and ordered to the *Philadelphia*.

## Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Feb. 11, 1904:

Brooks, S. D., surgeon, granted leave of absence for four months from April 1, 1904, with permission to go beyond the seas.

Magruder, G. M., surgeon, granted leave of absence for two days from February 13.

Greene, J. B., P. A. surgeon, granted fifteen days' extension of sick leave from February 10.

Clark, Taliaferro, P. A. surgeon, to proceed to San Juan, P. R., and assume temporary charge during the absence of the chief quarantine officer.

Richardson, T. F., and King, W. W., asst.-surgeons, to report March 9, 1904, to chairman of examining board at Washington, D. C., to determine their fitness for promotion to the grade of P. A. surgeon.

Ramus, Carl, asst.-surgeon, to report, March 9, 1904, to chairman of examining board at San Francisco for examination to determine his fitness for promotion to the grade of P. A. surgeon.

Moore, Dunlop, Holt, J. M., Vogel, C. W., and Fox, Carroll, asst.-surgeons, to report, July 25, 1904 to the recorder of examining board at Manila, P. I., for examintion to determine their fitness for promotion to the grade of P. A. surgeon.

Goldberger, Joseph, asst.-surgeon, granted leave of absence for one month from February 10.

BOARDS CONVENED.

Board convened at San Francisco for the examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; Asst.-surgeon Carl Ramus, recorder.

Board convened at the Marine Hospital, Port Townsend, Wash., Feb. 15, 1904, for the examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon J. H. Oakley, chairman; P. A. Surgeon M. H. Foster, recorder.

Board to meet at the Marine Hospital, San Francisco, March 9, 1904, to examine Asst.-surgeon Carl Ramus to determine his fitness for promotion to the grade of P. A. surgeon. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; P. A. Surgeon Rupert Blue; P. A. Surgeon H. S. Cumming, recorder.

Board to meet at Washington, D. C., March 9, 1904, to examine certain assistant surgeons to determine their fitneess for promotion to the grade of passed assistant surgeon. Detail for the board: Asst.-Surgeon-General A. H. Glennan, chairman; Asst.-Surgeon-General G. T. Vaughan; Asst.-Surgeon-General H. D. Geddings, recorder.

Board convened to examine certain assistant surgeons to determine their fitness for promotion to the grade of passed assistant surgeon. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon-General W. J. Pettus; P. A. Surgeon V. G. Heiser, recorder.

## Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Feb. 12, 1904:

SMALLPOX—UNITED STATES.

[illegible]co, Jan. 24-31, 3 cases.
[illegible]30-Feb. 6, 1 case.
[illegible] Jan. 30-Feb. 6, 5 cases.
Maine: Calais, Feb. 7, 5 cases; Madison, Jan. 28, 1 case.
Maryland: Baltimore, Jan. 30-Feb. 6, 1 case.
Michigan: Jan. 23-30, 88 places; Jan. 30-Feb. 6, Detroit, 3 cases; Flint, 1 case.
New Hampshire: Manchester, Jan. 30-Feb. 6, 9 cases.
New Jersey: Jan. 30-Feb. 6, Newark, 1 case; Trenton, 3 cases, 1 death.
New York: Jan. 30-Feb. 6, Niagara Falls, 1 case; New York, 5 cases.
Ohio: Jan. 30-Feb. 6, Bucyrus, 9 cases; Dayton, 12 cases; Cincinnati, Jan. 22-Feb. 5, 6 cases.
Pennsylvania: Jan. 30-Feb. 6, Allentown, 2 cases; Butler, 1 case; Johnstown, 5 cases; McKeesport, 2 cases; Philadelphia, 54 cases, 16 deaths; Pittsburg, 5 cases, 1 death; Warren, Jan. 1-Feb. 1, 10 cases, 2 deaths.
Tennessee: Nashville, Jan. 30-Feb. 6, 8 cases.
Utah: Ogden, Jan. 1-31, 1 case; Salt Lake City, Jan. 30-Feb. 6, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Dec. 12-Jan. 2, 2 cases, 2 deaths.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 9-16, 5 cases.
Belgium: Liege, Jan. 9-16, 1 case, 1 death.
Brazil: Rio de Janeiro, Jan. 3-10, 34 cases, 22 deaths.
Canada: Ontario, Dec. 1-31, 13 cases.
Chile: Antofogasta, Dec. 1-31, 3 deaths.
China: Shanghai, Dec. 19-26, 6 deaths.
Colombia: Barranquilla, Jan. 12-18, 1 death.
France: Paris, Jan. 16-23, 17 cases, 9 deaths.
Great Britain: Jan. 9-16, Nottingham, 5 cases, 1 death; Sheffield, 1 case; Jan. 16-23, Hull, 1 case; Liverpool, 1 case; London, 3 cases; Manchester, 2 cases; Newcastle-on-Tyne, 3 cases; Glasgow, Jan. 22-29, 71 cases; 2 deaths.
India: Bombay, Jan. 5-12, 6 deaths; Karachi, Jan. 3-10, 2 cases.
Mexico: Tampico, Jan. 24-31, 1 death.
Netherlands: Rotterdam, Jan. 16-23, 1 case.
Russia: Moscow, Jan. 2-9, 2 cases, 2 deaths; Jan. 9-16, Odessa, 1 death; St. Petersburg, 18 cases, 3 deaths.
Spain: Barcelona, Jan. 10-20, 5 cases; Santander, Jan. 18-26, 4 cases, 2 deaths.
Turkey: Smyrna, Jan. 3-18, 9 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Jan. 2-9, 1 case.
Mexico: Jan. 17-30, Merida, 1 case, 1 death; Tehuantepec, 2 cases, 2 deaths; Vera Cruz, Jan. 23-30, 1 case, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Dec. 12-Jan. 2, Manila, 9 cases, 8 deaths; Provinces, 44 cases, 33 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Dec. 26-Jan. 9, 30 deaths.
Turkey in Asia: Nindieh, Dec. 12-19, 2 deaths; Kerbela, Dec. 11-22, 422 deaths; Messieb, Dec. 18-20, 32 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Dec. 12-Jan. 2, 1 case, 1 death.

PLAGUE—FOREIGN.

Australia: Queensland, Cairns, Dec. 5, 2 cases.
Rio de Janeiro: Jan. 3-10, 10 cases, 5 deaths.

India: Bombay, Jan. 5-12, 186 deaths; Calcutta, Dec. 26-Jan. 9, 33 cases; Karachi, Jan. 3-10, 8 cases, 5 deaths.

Mauritius: Dec. 31-Jan. 7, 55 cases, 37 deaths.

South Africa: Natal, Dec. 5-12, 2 cases.

## Medical Organization.

### California.

San Benito County Medical Society.—A meeting of physicians of the county was called by Dr. Philip M. Jones, San Francisco, trustee of the state medical society, at Hollister, January 24, for the purpose of organizing a county society on the standard plan. Dr. James H. Tebbetts, Hollister, was elected temporary chairman. A constitution and by-laws in conformity with those of the state society were adopted, and the following permanent officers elected: President, Dr. James H. Tebbetts, vice-presidents, Dr. Richard W. O. Bannon; secretary, Dr. Joseph M. O'Donnell; treasurer, Dr. Leonard C. Hull, and censors, Drs. Francis O. Nash, Ian Don Ball, and George C. Porter, all of Hollister.

### Ohio.

Hancock County Medical Society.—Complete organization of this society was effected at a meeting held in Findlay, February 4. The following officers were elected: President, Dr. John C. Tritch, Findlay; vice-president, Dr. Leroy S. Woods, Rawson; secretary, Dr. John M. Firmin, Findlay; treasurer, Dr. Joseph P. Baker, Findlay; delegate to state society, Dr. Jacob A. Kimmel, Findlay; censors, Drs. Norman L. McLachlan, Findlay, Myron J. Ewing, Findlay, and Edward G. Hersh, McComb, and committee on public health and legislation, Drs. Francis W. Firmin, Alfred W. Balsley and Herbert V. Beardsley, all of Findlay.

Lake County Medical Society.—Dr. Thomas C. Martin, Cleveland, secretary of the council of the Ohio State Medical Association, and councilor for the Fifth District, met the physicians of the county at Painesville, February 6, detailed the standard plan of organization, enumerated its benefits, and aided in the organization of a county society. The standard constitution and by-laws were adopted, and the following officers elected: Dr. Edward B. Root, Painesville, president; Dr. Henry E. York, Fairport, vice-president; Dr. Thomas M. Moore, Willoughby, secretary; Dr. H. N. Amidon, Painesville, treasurer; Dr. Harris G. Sherman, Painesville, delegate to state society; Drs. David J. Merriman, Painesville, John W. Lowe, Mentor, and Charles H. Quayle, Madison, censors, and Drs. Charles F. House, Painesville, David J. Merriman, Painesville, and Thomas M. Moore, Willoughby, committee on public health and legislation.

### Texas.

Fifth District Medical Society.—Representatives from sixteen counties of this district met at San Antonio, February 2. Dr. Malone Duggan, Eagle Pass, Maverick County, was elected temporary chairman, and Dr. Marvin B. Grace, Seguin, Guadalupe County, temporary secretary. After Dr. Witten B. Russ, San Antonio, councilor for the district had stated the object of the meeting, a committee, consisting of Drs. Alonzo Garwood, New Braunfels, Comal County, and John V. Spring and Witten B. Russ of San Antonio, Bexar County, was appointed to draft a constitution and by-laws. At the evening session this committee made its report, and presented a constitution and by-laws, which were adopted. The following officers were elected: President, Dr. Malone Duggan, Eagle Pass, Maverick County; vice-presidents, Drs. J. R. Evans, Devine, Medina County, William S. Pickett, Karnes City, Karnes County, Charles W. Watt, Uvalde, Uvalde County, Henry Leonard New Braunfels, Comal County, David H. Houston, Floresville, Wilson County, Asa M. Stamps, Seguin, Guadalupe County, and R. N. Lane, Eagle Pass, Maverick County; secretary, Dr. Marvin B. Grace, Seguin, Guadalupe County; treasurer, Dr. John T. Fitzsimon, Castroville, Medina County, and censors, Drs. Alonzo Garwood, New Braunfels, Comal County, W. A. King, Falls City, Karnes County, and William Myers, Seguin, Guadalupe County.

## Society Proceedings.

### ACADEMY OF MEDICINE OF CLEVELAND.

*Regular Meeting, held Jan. 15, 1904.*

The President, Dr. George W. Crile, in the Chair.

Dr. S. W. Kelly described and exhibited a new truss for abdominal hernia.

#### Ankylosis and Caries Due to Gonorrheal Infection.

Dr. C. A. Hamann said that joint affections of various kinds may be caused by the gonococcus, and ankylosis is a frequent result of the inflammatory process. Broadhurst mentions a case where every joint in the body became ankylosed. The union is usually fibrous, but there may be true bony ankylosis. One group of cases, the milder form, shows no change in the position of the limb and no contractures, but in two of the cases here reported, although there was no deformity there was extensive destruction of the joint. In the other group of cases there are various displacements and muscular contractures; destruction of the joint surfaces may follow with resulting ankylosis, shortening and lameness.

Case 1.—The patient had gonorrhea seven months before Dr. Hamann saw him, the hip became painful and fibrous ankylosis in the extended position of the limb developed. There was little, if any motion of the joint, but there was a sort of springiness and the periarticular muscle became contracted on attempting to move the joint. Under an anesthetic, and by using considerable force the adhesions were broken down, there was marked improvement, but not complete restoration of function.

Case 2.—Patient contracted gonorrhea, and within a month acquired gonorrheal rheumatism, affecting the right hip only. He spent three months in bed with the thigh abducted and flexed; on first sitting up he could not walk, but four weeks later could do so without a cane. Operation was performed four weeks after onset of the gonorrhea, which still existed, as was shown by gonococci in the urethral discharge. There was marked obliquity of the pelvis; curving of the lumbar spine; thigh flexed and abducted; right buttock flattened; gluteal crease oblique; base of right thigh broader than that of the left; no atrophy of muscles; distance between the right anterior superior spinous process and the inner condyle 16½ inches, left side 20 inches; trochanter major not below Nélaton's line; this was determined at the operation, but not distinctly felt previously, as it was deeply placed; foot was everted. The symptoms were those of an obturator dislocation, and it was so regarded at first. Under anesthesia the supposed dislocation could not be reduced, nor could any motion be obtained in the joint, the joint was therefore incised, and the head of the bone found firmly united by bone with the acetabulum. The neck of the femur was divided close to the trochanter, the bony surfaces modeled into close relation and the limb put up in extension; a plaster cast was employed later and a good result obtained; the patient can walk with a cane, the hip is extended, and there is some shortening. As the patient has not been seen lately, it is unknown whether there is bony union or movement in the new joint.

In a search of the literature Dr. Hamann could find but one case each of excision of the hip and of the knee for gonorrheal arthritis; the following cases should, therefore, prove of interest.

Case 3.—Patient contracted gonorrhea in June, 1903, within a month had pain in right hip, knee and ankle; pain severe; contractures developed; medication had no effect, the position of limb was corrected under anesthesia and a cast applied. In October there was thickening of right hip, eversion of limb and pain on pressure or motion, fever 101-102 for a time. The condition resembled either tuberculosis or a neoplasm. At the operation in November the head of the femur and acetabulum were found to be eroded from granular ostitis; the cartilage and ligamentum teres were destroyed; there was no pus but granulation tissue, some partly organized, was found. The case appeared to be tubercular and was treated as such by excision of the joint and thorough curetting of the diseased tissue. The case progressed very favorably; the result is all that could be desired. The pathologic examination showed granulation tissue, but no evidences of tuberculosis, such as giant cells, etc., could be found; no tubercle bacilli or other bacteria could be found in stained sections; cultures were negative. Syphilis having been excluded and there being no evidence of tuberculosis, the process was thought to be due to the gonococcus.

CASE 4.—The patient, 41 years old, while suffering from gonorrhea began to have pain in left hip, knee and shoulder, 2½ months before admission to the City Hospital. He had also some fever and sweating, and had lost weight rapidly for the previous month. The usual treatment for gonorrheal rheumatism served merely to lessen the pain in the knee. Two months after admission the left hip was tender on pressure, and there was pain on attempted motion; the limb was extended and there was no fever; the joint was visibly thickened and the condition resembled that of the last case. As there was no improvement the joint was excised and the diseased tissue curetted away. No pus was found, but masses of granulation tissue and semi-organized lymph occupied the joint; the articular surfaces of the femur and acetabulum were eroded and the cartilages and ligamentum teres were partly destroyed. The wound healed by first intention. Bacteriologic examination of the diseased tissue gave one culture on ascites bouillon of a diplococcus morphologically like the gonococcus and decolorizing by Gram's method, other cultures were negative. Pathologically irregular areas of necrosis were found on the articular surface of the femur, no pus was found. Microscopically no giant cells or other evidences of tuberculosis could be found. Sections stained for tubercle bacilli and gonococci were negative.

In addition to these two cases Dr. Hamann has excised the wrist joint for a similar condition.

### DISCUSSION.

DR. F. BUNTS said that the existence of gonorrhea seemed to cause an increased liability to tuberculosis. The gross appearances of these two joint affections are very similar, but the microscopic examination will clear up the diagnosis. Most joint complications in gonorrhea occur within a month of the onset of the disease; the involvement of the hip is relatively infrequent. The operative results are very favorable and differ from those in tuberculosis by the wounds' healing readily without any troublesome sinuses.

DR. HAMANN said that medical treatment should first be tried, but the results were usually poor. If caries or ankylosis were present or if the patient was growing worse operation was indicated. Arthrotomy and antiseptic irrigation might be sufficient, but resection might be necessary.

DR. MARTIN FRIEDRICH read a paper on "How the Water Supply of Butler Became Infected," giving his conclusions from observations made on the scene.

---

## Book Notices.

THE NATURE OF MAN. Studies in Optimistic Philosophy. By Elie Metchnikoff, Professor at the Pasteur Institute. The English Translation. Edited by P. Chalmers Mitchell, M.A., D.Sc., Oxon., Secretary of the Zoological Society of London. Cloth. Pp. 309. Price, $2.00 net. New York and London: G. P. Putnam's Sons. 1903.

This work, which has been widely noticed in the secular press and almost universally with favor, is a striking contribution of the day. The author needs no introduction to medical readers, but the present volume will probably be a revelation in some respects to most of them. It is the work of a biologist as well as that of a physician and bacteriologist, and the author accepts the most advanced materialism of the period. He begins by speaking of the discontent and uneasiness that exist throughout the world to-day, the desire for universal happiness and the failure thus far to find the right way to obtain it. Religion, he asserts, has failed, and man has developed into a condition where his organism is in many respects out of accord with Nature about him. He foresees a remedy for the present state of affairs in the general adoption of the teachings of exact science as a guide for human conduct. It might, perhaps, be questioned just what an exact science is in these days when the discoveries that are crowding on each other seem to overthrow our opinions of such solid facts as matter and such universal agencies as force. Science has not yet reached the point of absolute exactness nor do we feel depressed by the fact, as Professor Metchnikoff seems to be, that there are yet probably unsolvable problems before us. A large proportion of the work is given to the subject of "disharmonies," as he calls them, that are found in the human organism. Man, he says—and it seems to us somewhat of an assumption—is the result of a miscarriage of an anthropoid ape born before the complete development of simian characters and while the embryo was still in a stage in which the higher nervous centers most predominated. The reasons why the simian embryo should be more human before its complete development and extrusion are not very clear nor are they given here, but such seems to be a fact. Coming thus, as it were, unprepared on the world, Professor Metchnikoff seems to think it is only natural that man finds himself at many disadvantages. A sudden change in the natural conditions is brought about and, he says, a large series of organized disharmonies arise which become more acutely felt as man becomes more delicate and sensitive. The greatest disharmonies are those of the morbid nature of old age and the impossibility of reaching the instinct of natural death. Metchnikoff prophesies that many of these disadvantages will be overcome by the acquisitions of science and by the study of the human constitution. Human life will then be prolonged far beyond its present limit and death will come to the individual not as a dreaded event, but as one looked for and as altogether a natural process in his existence. It is a little remarkable that, with his rejection of religion throughout, he puts such apparent faith in the early histories of the patriarchs and their prolonged existence. Under the new arrangement he looks for, old age will have its functions, social and political, far beyond its present possibilities. It will not be a hardship or useless existence, but the crowning period of a useful life. The prospect is a very pleasant one, provided one accepts the author's views in their entirety. Most people, however, are so constituted that exact science does not seem to them a cure-all for the evils of life. They must look forward to something supernatural—as directing their future. Professor Metchnikoff's former master, Pasteur, was one of them, and yet he was none the less a scientific man. There is also something in the view that there is an eternal justice in the management of the universe, and that the evils that now exist are yet to be compensated for. No sociologic dreamer or scientific thinker has worked out—either on the basis of man's present organization or even on that of his future superior organization—a social system that will entirely do away with the difficulties that now surround him.

GYNECOLOGY. A Text-Book for Students and a Guide for Practitioners. By William R. Pryor, M.D., Professor of Gynecology in the New York Polyclinic Medical School. 163 Illustrations in the Text. Cloth. Pp. 380. Price, $3.50. New York and London: D. Appleton & Co. 1903.

The author of this volume is a practical man, and "practical" is the characteristic element that is in evidence throughout the work. The work is neither elaborate nor comprehensive, but deals in a concise and practical manner with "those subjects which are strictly gynecologic and on which a professor of gynecology usually has to lecture." The author does not consider it "the province of a gynecologist to illustrate the findings of the microscopist or of the anatomist," consequently he does not present the histopathology of the various affections, but treats of them only from what may be called a practical clinical point of view. The well-known views of the author concerning the vaginal route, and particularly early drainage through the posterior cul-de-sac, in acute infections of the pelvic organs are clearly brought out. The chapter on fibroids is especially good. In reading the work one can not fail to learn many useful and valuable points, and to be impressed with the earnestness and clearness with which the author at all times expresses his views.

INFECTION AND IMMUNITY, with Special Reference to the Prevention of Infectious Diseases. By George M. Sternberg, M.D., LL.D., Surgeon-General U. S. Army (retired), Ex-president of the American Medical Association. Cloth. Pp. 293. Price, $2.00. New York and London: G. P. Putnam's Sons. 1903.

The public is more than ever before inquiring regarding the cause and prevention of disease, and asking what can be done by individuals to ward off-illness. The charlatan and quack understand this and prepare plenty of literature calculated to bring people to them. It is well, therefore, that there is also a constantly increasing literature on health matters for the sensible inquirer, written by honorable and scientific men, and which is calculated to help rather than to injure those who read it. Sternberg's book on infection and immunity is one of the latest to be added to this class of literature. While the book is written for the layman, it is none the less scientific and reliable. Each subject is presented with the view of giving known facts as such, and unproved theories for what they are worth. The subject is presented in two parts. In the first, infection and disinfection, natural and acquired immunity, antitoxin, etc., are considered. In the second part, infectious diseases are discussed, twenty in all, each being given a special chapter. The methods of propagation and the best means of prevention of each particular disease are considered, including also statistical, historical, and other data. The keynote of the book is that all infectious diseases are preventable diseases and that it is now possible to carry out preventive measures in practically all of them. The book is one that the physician himself can read with profit, but especially is it one that he can recommend to his patients.

The Prevention of Consumption. By Alfred Hillier, M.D., C.M., B.A., Secretary of the National Association for the Prevention of Consumption (London). Revised by Professor R. Koch. With Illustrations. Cloth. Pp. 226. Price, $1.50 net. New York and Bombay: Longmans, Green & Co. 1903.

This is one of the many works called out in the present active crusade against the "great white plague." The author has already made himself some reputation by previous work on this subject. The introduction by Prof. Robert Koch is a recommendation that will go far to introduce the work to English-speaking readers. It covers the subject of prophylaxis and treatment of consumption in a concise and yet in a rather thorough way. The author's views are those which seem to be generally prevalent on the subject. He believes in the communicability of the disorder, and the counsel given can be safely followed. The work is a good one for popular circulation. As regards Koch's theory of the non-communicability of bovine tuberculosis, the author assumes a sort of middle ground, considering that while there are evidences in favor of the view there are also other cases where human infection can not be disregarded and the practical conclusion which he reaches that cow's milk should be boiled before consumption as a human food is certainly well on the safe side. As an exposition of the latest scientific views the work is to be recommended.

Treatment of Neurasthenia. By A. Proust, Professor à la Faculté de Médecine de Paris, and Gilbert Ballet, Professor agrégé à la Faculté de Médecine de Paris Medecin de l'hopital Saint-Antoine. Translated by Peter Campbell Smith, L.R.C.P., L.R.C.S., Edin., L.F.P.S., Glasg. Cloth. Pp. 213. Price, $2.00. New York: Edward R. Pelton. 1903.

Smith has rendered a service to English-speaking readers by translating this well-known work of Proust and Ballet on this protean, but everywhere prevalent, disorder. The reputation the work has already earned abroad for its scientific presentation of the subject saves us the necessity of adding additional commendation. The author has tried to be as literal as possible in his translation, but has nevertheless rendered it into excellent English, and has preserved the clearness of the original French style. The size of the work is convenient, it is almost a pocket manual, and will be received with favor.

Modern Microscopy. A *Handbook for Beginners and Students.* Combining: 1. The Microscope and Instructions for Its Use, by M. I. Cross. 2. Microscopic Objects, How Prepared and Mounted, by Martin J. Cole, Lecturer in Histology at Cooke's School of Anatomy. Third Edition. Entirely Revised and Enlarged, to which is Added 111 Microtomes, Their Choice and Use. Cloth. Pp. 292. Price, $1.50. Chicago: W. T. Keener & Co. 1903.

This book has been entirely revised. It covers the subject of microscopy, mechanism and management of the microscope and its accessories, and to a very large extent the methods of microscopic preparation. It is not essentially a medical work, but is one that may be useful to the physician as well as to the general student of biology. The illustrations are numerous, and in many ways elucidate the points made in the text. The publisher's part of the work is in every way commendable.

King's Manual of Obstetrics. By A. F. A. King, M.D., Professor of Obstetrics and Diseases of Women in the Medical Department of the Columbian University, Washington, D. C. Ninth Edition, Revised and Enlarged. Cloth. Pp. 628. Price, $2.50 net. Philadelphia and New York: Lea Brothers & Co. 1903.

That this text-book has passed through nine editions is sufficient evidence of its having given satisfaction to the medical public. Some changes have been made. The chapter on puerperal septicemia has been for the most part rewritten, and the author has made use of the work of others, as he acknowledges in his preface. The book is well up to date, and is a reliable, though a brief, treatise on its special branch of medicine.

A Compend of Diseases of the Skin. By Jay F. Schamberg, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine. Third Edition, Revised and Enlarged. With 106 Illustrations. Cloth. Pp. 291. Price, 80 cents. Philadelphia: P. Blakiston's Son & Co. 1903.

This third edition is practically the same as previous ones. We have stated our idea of the field in which quiz-compends are useful and, as such a work, this book is excellent. A great deal, of course, can not be expected in the portrayal of skin diseases by black and white illustrations, but these here given are fairly good.

Prostatic Hypertrophy, from Every Surgical Standpoint. By George M. Phillips, M.D., and Forty Distinguished Authorities. Edited and Compiled by S. C. Martin, Jr., M.D. Cloth. Pp. 176. Price, $1.75. St. Louis: Lewis S. Matthews & Co.

This little work consists of answers of numerous prominent surgical operators to a series of questions that were sent out by the editor and compiler, preceded by a brief sketch of the anatomy of the prostate and its physiology and pathology.

## Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Gonorrhea.

After reiterating the disappointments following the employment of drugs in the treatment of gonorrhea in former years, H. M. Christian, in *Med. Bul.*, states that the mistakes in the past in the employment of strong solutions of silver nitrate have been the cause of the production of the present valuable silver compounds, each containing a certain percentage of the salt, ranging from four to thirty per cent. In the author's opinion the best of these preparations is argyrol, it being the least destructive and irritating to the urethral mucous membrane. After treating fifteen hundred cases of gonorrhea with argyrol the author corroborates the statements that it is free from irritation, though used in solutions as high as twenty per cent.; the gonococci on and beneath the mucous membrane are rapidly destroyed; the amount of urethral discharge is rapidly lessened and the duration of the disease is cut short. Attention is called to the important fact that argyrol alone will not effect a cure, because there remains a catarrhal urethritis, after the gonococci have been destroyed, which demands a special line of treatment. He advises, in the early inflammatory stage, the following combination to relieve the subjective symptoms:

℞. Salol
Sodii brom.
Potass. bicarb. āā....................℥ss 15|
M. Ft. chart. No. xxiv. Sig.: One every two hours.

At the same time he orders a 5 per cent. solution of argyrol to be used by the patient, as an injection, three or four times daily, the solution being retained in the urethra for ten minutes. It is advisable for the patient to wash out the anterior urethra with several syringefuls of warm normal saline solution just before injecting the silver solution. The author recommends this line of treatment for the first three weeks. After the subjective symptoms have subsided the local treatment in some cases may be substituted by the internal administration of copaiba and sandalwood. During the stage of decline an astringent injection is required, in addition to the silver solution, to benefit the mucous membrane, consequently the argyrol solution should be used at night and morning and the following injected three or four times during the day:

| | | | | |
|---|---|---|---|---|
| ℞. | Zinci sulph. | gr. x | | 65 |
| | Bismuthi subcarb. | ʒii | 8 | |
| | Liq. hydrastis (colorless) | ℥ss | 15 | |
| | Aq. destil. q. s. ad. | ℥iv | 120 | |

M. Sig.: Inject two drams three or four times daily; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Zinci sulph. | gr. xii | | 75 |
| | Plumbi acetatis | gr. xv | 1 | |
| | Liq. hydrastis | ℥ss | 15 | |
| | Aq. destil. q. s. ad. | ℥iv | 120 | |

M. Sig.: Two or three times daily as an injection.

At the beginning of the fifth week, when only the morning drop remains and the urine contains shreds, the argyrol solution should be used at night, and through the day one of the following combinations:

| | | | | |
|---|---|---|---|---|
| ℞. | Acidi carbol. | gr. iv | | 25 |
| | Zinci sulph. | | | |
| | Pulv. aluminis, āā | gr. xii | | 75 |
| | Aq. destil. q. s. ad. | ℥iv | 120 | |

M. Sig.: As an injection; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Cupri sulph. | gr. iv | | 25 |
| | Aq. destil. | ℥iv | 120 | |

M. Sig.: As an injection; or:

| | | | | |
|---|---|---|---|---|
| ℞. | Zinci chloridi | gr. iv | | 25 |
| | Aq. destil. | ℥iv | 120 | |

M. Sig.: As an injection two or three times daily.

### Pruritus Ani.

The treatment of pruritus ani, according to C. J. Drueck in *Surg. Clinic,* depends on the cause. When no apparent cause presents itself locally, then the general condition of the patient must be inquired into. Anemia or tubercular trouble, if present, must be corrected. The diet must be looked into and excesses cut off, such as coffee, meats, alcohol, spices and condiments. Any derangement of the stomach, liver or bowels must be corrected if possible. Syphilis will sometimes produce a pruritus of the anus and will be removed by a course of mercury and iodids.

The local treatment, according to the author, should consist in cleansing and keeping the parts dry, preventing friction and relieving sphincter spasm. In these cases it is recommended that the sphincter be gradually and thoroughly dilated, thus relieving the hypertrophy of the sphincter muscle and the hypersensitiveness of the anal mucous membrane. The local use of preparations containing opium must be used carefully on account of the possibility of contracting the habit and also because it has a tendency to produce a general itching. To give temporary relief the following combination is recommended by the author in preference to other soothing applications:

| | | | |
|---|---|---|---|
| ℞. | Camphoræ | | |
| | Chloratis hydratis, āā | ʒi | 4 |
| | Ung. diachylon | ℥i | 30 |

M. Ft. unguentum. Sig.: To be applied two or three times daily after bathing the part. Relief may also be obtained by brushing the parts with silver nitrate grains ten (.65) to the ounce (30.) of water. Pain will be produced for a short time only after this application. If thread worms are present, injections of lime water or salt water usually suffice, but in severer cases santonin may be given. When due to vaginal discharges, douches of a 1-2,000 bichlorid or a 2 per cent. lysol solution may be used twice daily. In infants, due to a lack of cleanliness, the following combination, applied locally, is preferred:

| | | | |
|---|---|---|---|
| ℞. | Acidi picrici | m. xlv | 3 |
| | Ung. hydrarg. nit. | ℥i | 30 |

M. Ft. ung. Sig.: Apply locally night and morning. General eczema is quite frequently the cause of this local condition. In such cases the tar preparations are of value. The parts may be bathed with a solution of alcohol and tar water. Or the following ointment may be used:

| | | | | |
|---|---|---|---|---|
| ℞. | Ol. picis liquidiæ | ʒii | 8 | |
| | Ung. belladonnæ | ʒi | 4 | |
| | Acidi carbol. | m. v | | 30 |
| | Adipis lanæ | ʒi | 4 | |

M. Ft. ung. Sig.: Apply locally after cleansing the parts.

The parts should be bathed frequently in hot water and tincture of green soap, to remove the thickened scales and to deplete the local circulation. In severe cases the following may be used:

| | | | | |
|---|---|---|---|---|
| ℞. | Potassii hydratis | gr. v | | 30 |
| | Aquæ | ℥i | 30 | |

M. Sig.: Apply locally. In the moist variety of eczema the following combination is of service:

| | | | | |
|---|---|---|---|---|
| ℞. | Thymol | gr. ii | | 12 |
| | Pulv. zinci stearat. | ℥iv | 120 | |

M. Ft. pulvis. Sig.: Apply locally.

In eczema marginata the author recommends that the parts be thoroughly cleansed, dried and an application of dilute sulphuric acid applied. This treatment, though producing pain temporarily, soon gives relief. The tincture of iodin may be used in its stead. In neurotic cases a narcotic may have to be given, such as bromid or chloral, to produce sleep.

### Drug Stimulation in Children.

For the purpose of stimulation in the treatment of disease in children the following preparations, according to Caillé, in *Post Grad.,* may be employed: Alcohol, camphor, strychnin, nitroglycerin, digitalis, ammonia. The cold douche may also be of service in effecting a reflex nerve stimulation. The heroic application of cold externally and in feeble children with poor circulation is, without doubt, detrimental. Consequently, whenever the child's extremities are cold and the temperature is high, a hot bath and enteroclysis is preferable treatment.

It is the opinion of the author that while alcohol can not build up the body it does serve as fuel for the body; at the same time it serves to stimulate respiration and consequently is of value in febrile diseases, and prolongs life. The amount of whiskey to be given in twenty-four hours may vary from dram one (4.) to ounces two (60.); Tokay wine, ounce one (30.) to ounces eight (240.), champagne, ounces two (60.) to ounces sixteen (500.). Mild stimulants, such as coffee, black tea and hot beef tea may be given in connection with or instead of alcohol. The following drugs may be used in the dosage given as stimulants:

Ether, drops two to six (.12-.40).
Camphor, grain one-fourth to one (.015-.06).
Infusion digitalis, one teaspoonful (4.00).
Spiritus etheris comp., drops two to ten (.12-.65), on sugar.
Aromatic spirits of ammonia, drops five to ten (.30-.65) in sugar water.

The following preparations can be given by the mouth, or subcutaneously:

Strychnin, gr. 1/50-1/30 (.0012-.0024).
Nitroglycerin, gr. 1/100-1/50 (.0006-.0012).
Caffein and sodium benzoati, grain i to iii (.06-.20) every three hours.

When the stomach is not disturbed the following combination is recommended by the author:

| | | | |
|---|---|---|---|
| ℞. | Pulv. camphoræ | | |
| | Pulv. digitalis, āā | gr. i | 06 |
| | Acidi benzoici | gr. iii | 20 |

M. Ft. chart. No. iv. Sig.: One every four hours in sweetmeats or chocolates.

Timely and judicious stimulation is very important in the treatment of febrile diseases in childhood, but overstimulation is cautioned against, remembering that the reserve power in children can, as a rule, be depended on, except in malignant sepsis.

Stimulation by drugs is non-indicated as long as the pulse is full and strong, and in fact is injurious, but when the pulse becomes weak and compressible, and before it becomes intermittent, stimulation should be resorted to.

### Bronchopneumonia.

In the treatment of bronchopneumonia in children, it is important to make the child as comfortable as possible, accord-to bring people to them. It is well, therefore, that there is also a constantly increasing literature on health matters for the sensible inquirer, written by honorable and scientific men, and which is calculated to help rather than to injure those who read it. Sternberg's book on infection and immunity is one of the latest to be added to this class of literature. While the book is written for the layman, it is none the less scientific and reliable. Each subject is presented with the view of giving known facts as such, and unproved theories for what they are worth. The subject is presented in two parts. In the first, infection and disinfection, natural and acquired immunity, antitoxin, etc., are considered. In the second part, infectious diseases are discussed, twenty in all, each being given a special chapter. The methods of propagation and the best means of prevention of each particular disease are considered, including also statistical, historical, and other data. The keynote of the book is that all infectious diseases are preventable diseases and that it is now possible to carry out preventive measures in practically all of them. The book is one that the physician himself can read with profit, but especially is it one that he can recommend to his patients.

The Prevention of Consumption. By Alfred Hillier, M.D., C.M., B.A., Secretary of the National Association for the Prevention of Consumption (London). Revised by Professor R. Koch. With Illustrations. Cloth. Pp. 226. Price, $1.50 net. New York and Bombay: Longmans, Green & Co. 1903.

This is one of the many works called out in the present active crusade against the "great white plague." The author has already made himself some reputation by previous work on this subject. The introduction by Prof. Robert Koch is a recommendation that will go far to introduce the work to English-speaking readers. It covers the subject of prophylaxis and treatment of consumption in a concise and yet in a rather thorough way. The author's views are those which seem to be generally prevalent on the subject. He believes in the communicability of the disorder, and the counsel given can be safely followed. The work is a good one for popular circulation. As regards Koch's theory of the non-communicability of bovine tuberculosis, the author assumes a sort of middle ground, considering that while there are evidences in favor of the view there are also other cases where human infection can not be disregarded and the practical conclusion which he reaches that cow's milk should be boiled before consumption as a human food is certainly well on the safe side. As an exposition of the latest scientific views the work is to be recommended.

Treatment of Neurasthenia. By A. Proust, Professor à la Faculté de Médecine de Paris, and Gilbert Ballet, Professor agrégé à la Faculté de Médecine de Paris Medecin de l'hopital Saint-Antoine. Translated by Peter Campbell Smith, L.R.C.P., L.R.C.S., Edin., L.F.P.S., Glasg. Cloth. Pp. 213. Price, $2.00. New York: Edward R. Pelton. 1903.

Smith has rendered a service to English-speaking readers by translating this well-known work of Proust and Ballet on this protean, but everywhere prevalent, disorder. The reputation the work has already earned abroad for its scientific presentation of the subject saves us the necessity of adding additional commendation. The author has tried to be as literal as possible in his translation, but has nevertheless rendered it into excellent English, and has preserved the clearness of the original French style. The size of the work is convenient, it is almost a pocket manual, and will be received with favor.

Modern Microscopy. A Handbook for Beginners and Students. Combining: 1. The Microscope and Instructions for Its Use, by M. I. Cross. 2 [illegible] How Prepared and Mounted, by Martin J. [illegible] ology at Cooke's School of Anatomy. Thir[illegible] ised and Enlarged, to which is Added 111 M[illegible] and Use. Cloth. Pp. 292. Price, $1.50. Chicago: W. T. Keener & Co. 1903.

This book has been entirely revised. It covers the subject of microscopy, mechanism and management of the microscope and its accessories, and to a very large extent the methods of microscopic preparation. It is not essentially a medical work, but is one that may be useful to the physician as well as to the general student of biology. The illustrations are numerous, and in many ways elucidate the points made in the text. The publisher's part of the work is in every way commendable.

King's Manual of Obstetrics. By A. F. A. King, M.D., Professor of Obstetrics and Diseases of Women in the Medical Department of the Columbian University, Washington, D. C. Ninth Edition, Revised and Enlarged. Cloth. Pp. 628. Price, $2.50 net. Philadelphia and New York: Lea Brothers & Co. 1903.

That this text-book has passed through nine editions is sufficient evidence of its having given satisfaction to the medical public. Some changes have been made. The chapter on puerperal septicemia has been for the most part rewritten, and the author has made use of the work of others, as he acknowledges in his preface. The book is well up to date, and is a reliable, though a brief, treatise on its special branch of medicine.

A Compend of Diseases of the Skin. By Jay F. Schamberg, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine. Third Edition, Revised and Enlarged. With 106 Illustrations. Cloth. Pp. 291. Price, 80 cents. Philadelphia: P. Blakiston's Son & Co. 1903.

This third edition is practically the same as previous ones. We have stated our idea of the field in which quiz-compends are useful and, as such a work, this book is excellent. A great deal, of course, can not be expected in the portrayal of skin diseases by black and white illustrations, but these here given are fairly good.

Prostatic Hypertrophy, from Every Surgical Standpoint. By George M. Phillips, M.D., and Forty Distinguished Authorities. Edited and Compiled by S. C. Martin, Jr., M.D. Cloth. Pp. 176. Price, $1.75. St. Louis: Lewis S. Matthews & Co.

This little work consists of answers of numerous prominent surgical operators to a series of questions that were sent out by the editor and compiler, preceded by a brief sketch of the anatomy of the prostate and its physiology and pathology.

## Therapeutics.

[*Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.*]

### Gonorrhea.

After reiterating the disappointments following the employment of drugs in the treatment of gonorrhea in former years, H. M. Christian, in *Med. Bul.*, states that the mistakes in the past in the employment of strong solutions of silver nitrate have been the cause of the production of the present valuable silver compounds, each containing a certain percentage of the salt, ranging from four to thirty per cent. In the author's opinion the best of these preparations is argyrol, it being the least destructive and irritating to the urethral mucous membrane. After treating fifteen hundred cases of gonorrhea with argyrol the author corroborates the statements that it is free from irritation, though used in solutions as high as twenty per cent.; the gonococci on and beneath the mucous membrane are rapidly destroyed; the amount of urethral discharge is rapidly lessened and the duration of the disease is cut short. Attention is called to the important fact that argyrol alone will not effect a cure, because there remains a catarrhal urethritis, after the gonococci have been destroyed, which demands a special line of treatment. He advises, in the early inflammatory stage, the following combination to relieve the subjective symptoms:

℞. Salol
Sodii brom.
Potass. bicarb. āā....................℥ss 15|
M. Ft. chart. No. xxiv. Sig.: One every two hours.

At the same time he orders a 5 per cent. solution of argyrol to be used by the patient, as an injection, three or four times daily, the solution being retained in the urethra for ten minutes. It is advisable for the patient to wash out the anterior urethra with several syringefuls of warm normal saline solution just before injecting the silver solution. The author recommends this line of treatment for the first three weeks. After the subjective symptoms have subsided the local treatment in some cases may be substituted by the in-

*February 6.*

1 *A Brief Review of the Etiology of Yellow Fever. (To be concluded.) James Carroll.
2 *Observations on the Quantity of Day and Night Urine. Charles W. Edmunds.
3 *Infantile Bronchitis. E. M. Sill.
4 *The Sanitary Needs of Panama. M. L. Maduro.
5 *A Suggestion for the Rapid Calculation of Percentage Milk Mixtures: with Description of a Mechanical Device for the Instantaneous Calculation of Such Formulæ. Thompson S. Westcott.

1. **Yellow Fever.**—Carroll gives the history of the discovery of yellow fever down to the conclusive investigations at Havana.

2. **Day and Night Urine.**—Edmunds finds the passing of urine to be about .67 during the day and .33 during the night. There may be considerable variation even up to equal amounts, but this is exceptional without decided disease. He tabulates a study of 56 cases, including cases of croupous pneumonia, scarlet fever, typhoid and renal and cardiac disease, and finds that the changes in certain cases from or toward the normal ratio are but expressions of the changes which take place in the patient's renal and cardiac condition, and may be used as an index to the progress of the patient. His results also confirm the earlier writers' views as to the nocturnal polyuria occurring in renal and cardiac disease, and point out the value of this fact as a diagnostic sign especially in cardiac disease. He also suggests the possibility of tracing the course of a nephritis or of a cardiac disease by observing the changes in the relative amount of day and night urine for short intervals at a time. When drugs which cause diuresis are administered during the day they tend to restore the normal ratio.

3. **Infantile Bronchitis.**—Sill describes the course of bronchitis in infants, and emphasizes the necessity of frequent and careful examinations of the changes found in the milder forms which may almost at once change to the severe. He condemns the use of remedies designed to allay the cough, as the indication is to get rid of the excessive secretions and not to have them retained. The question as to whether the cough is excessive or not is dependent on the ability of the lung to rid itself of the secretions in its bronchial tubes.

4. **The Sanitary Needs of Panama.**—Panama appears to be in a bad condition, and, according to Maduro, the conditions which exist there are largely avoidable. There is no good water supply and but a single imperfect sewer. The house drainage and plumbing are poor. He would advise the tearing down of the rookeries in which the very poor live, transferring their occupants to better built, lighted and ventilated buildings, however cheap. Other needs are an organized street-cleaning department, the opening up of the dark narrow streets to sunlight and the filling in of old vaults and cisterns, the appointment of a well-equipped board of health and the exercise and control of the milk supply, the prevention of food adulteration, and, lastly, strict quarantine regulations.

5. **Milk Percentage.**—Westcott describes a method of computing the milk percentage by two revolving disks superimposed on each other in which are openings reading on a still lower disk. By the proper use of this device an almost instantaneous method is obtained of determining the quantities of 16 per cent. cream, whole milk and sugar required to make any of the usual percentage formulæ for any quantity of total mixture.

### Boston Medical and Surgical Journal.

*February 4.*

6 *Report of Cases of Trephining for Epilepsy. John C. Munro.
7 *Some Conclusions Based on a Study of 134 Cases of Calculus of the Ureter. With a Report of Three Cases. Benjamin Tenney.

6. **Trephining for Epilepsy.**—While he knows of no more discouraging field than the operative treatment of epilepsy by trephining, Munro still thinks that there is a certain class of unfortunates which can be helped in some way unexplainable. He does not, of course, refer to cases with recent palpable cranial depressions or new growths, but to those where there may be some unexpected lesion of the cortex, pia or dura, only demonstrated by operation or at autopsy. He thinks surgical relief for the cure of reflex disturbances from the viscera is rightly due the epileptic as much as to other individuals. In the cases reported several were temporarily relieved, but the outlook is not encouraging.

7. **Calculus in the Ureter.**—Three cases are reported and the subject generally discussed. Tenney sums up with the following conclusions as regards symptoms, diagnosis and treatment:

> Intermittent pain on one side, with varying amounts of red blood in the urine, are constant symptoms of stone in the ureter.
>
> Though the best means of locating stones, the *x* ray can not yet give evidence sufficient in itself to warrant us in operating or refusing to operate on certain cases.
>
> If a calculus starts from kidney to bladder, it is likely to catch within an inch of one of three places, all of which are accessible to the surgeon through extra-peritoneal openings.
>
> A single calculus is the rule, but the exception occurs, according to these cases, about once in eight times.
>
> The opening in the ureter or kidney pelvis for removal of the calculus should be sutured if possible. Both sorts of suture materials have been used with equally good results, and wounds in both locations apparently heal equally well. The recovery is only delayed if sutures are not used.
>
> A calculus in the ureter is a menace not only to health, but to life, and its removal is an operation of low mortality, provided it is undertaken before secondary changes appear in the kidneys.

8 *Purinemia: A Clinical Study. Reynold W. Wilcox.
9 *The Life-study of Patients, or the Biographic and Multiple Biographic Method of Discovering Medical Truth. George M. Gould.
10 *Morton's Painful Disease of the Toes. Walter G. Stern.
11 Abscess of the Liver, Caused by Distomum Sinense of the Intrahepatic Bile Ducts. Thos. L. Rhoads.
12 *Some Observations on the Occurrence of Nephritis in Infancy. Charles C. Biedert.
13 *Myxedema Complicated with Diabetes Mellitus Occurring in Two Children. Effect of Thyroid Extract on Both Diseases. Remarks on the Pathogenesis of Diabetes. Alfred Gordon.
14 Medicus et Medica. (To be concluded.) Helen MacMurchy.

8. **Purinemia.**—Wilcox considers that endogenous uric acid is chiefly concerned in gout and purinemia. The uric, as well as the phosphoric acid excretion is merely an index of retrograde metamorphosis of the body nucleins. Since the endogenous uric acid is independent of the presence of animal food in the diet, the patient should be limited only in quantity in order to reduce the intake to the organism's needs. The part played by the liver in gout is a purely negative one; it is unable to act as a poison filter. The keynote to the treatment lies in first limiting all toxic influences and formation of toxins, particularly in the alimentary canal, in order to minimize the retrograde metamorphosis of the body nucleins, preventing the absorption of toxic material and promoting its elimination.

9. **Eyestrain, Etc.**—This article by Gould is a general review of his series of clinical studies of the cases of Carlisle, Browning, George Eliot, Parkman, Wagner and others. He insists on the importance of bringing a large number of clinical life histories into comparison and producing, as it were, a composite photograph of the complete pathologic findings. This method, he claims, applied to his subjects previously discussed has yielded unexpected discoveries, and demonstrated a unity of cause and of diverse symptoms that was wholly unforeseen. Eyestrain is the great secret in all these cases. It has an irritant action on the nervous system, and is responsible for the manifold ailments of the illustrious characters he has described, the nervous irritability, the restlessness and the call for muscle action, etc., which was so marked in these cases and which relieved them temporarily. The necessity for systematic re-examination by specialists of all the bodily organs and functions throughout life is emphasized. Besides the scientific values of such repeated examinations, they would often reveal pathologic conditions and trends of profound value to individuals and families.

10. **Morton's Disease of the Toes.**—This disorder, the existence of which is denied by the French school, is explained

flexion and adduction of the foot. The value of the strap (stirrup) splint of plaster of paris in the treatment of Pott's fracture is also specially insisted on.

29. **Stomach Disorders in Diabetes.**—Sawyer reviews the opinions and gives experiences with cases of diabetes in which gastric lavage and other methods were employed with remarkable results. He feels justified, on the basis of clinical experience, to hold that instead of regarding stomach disorders as of trifling importance due to sugar in the blood and to be regarded lightly, stomach affections are in many cases likely to afford a point of attack by which a degree of relief from distressing symptoms and the prolongation of life and efficiency may be secured better than by general indifference to the significance of these disorders in diabetes.

33 *Speichelsteine. (Salivary Calculi.) G. Schirmer.
34 *Ein Beitrag zur Behandlung des Asthmas. (Treatment of Asthma.) Carl F. Kremer.
35 Der Nutzen der Formalin-Lampe "Hygiea," insebesondere bei Keuchhusten. (Use of Formalin Lamp, Especially in Pertussis.) Dr. Sembritzki.

33. **Salivary Calculi.**—Schirmer describes these formations and speaks of the value of the *x*-ray in their diagnosis, though it has been decried by some recent writers. He gives illustrative cases of its use. With the diagnosis made, of course, the only treatment is operation. This should be done, as a rule, by way of the mouth; sounding of the duct is unnecessary. It is best to go directly to the foreign body and scoop it out with a spoon. Salivary fistula in the mouth is of no importance.

34. **Asthma.**—Kremer speaks favorably of the use of atropin in this disorder, recognizing, of course, the value of ether, amyl nitrite, nitroglycerin, etc., for the attacks; also morphin subcutaneously and the necessity for care as to hygiene, diet, etc. In his cases he begins with 1/120 gr. of atropin as near the beginning of the attack as possible, injecting it subcutaneously two and seldom three times in the twenty-four hours. He says by this treatment the generally long-lasting painful attacks will be quickly relieved and the exhaustive cough cease. Bronchial catarrh is favorably influenced, the emphysema disappears and the condition of the patient, mental, etc., rapidly improves.

42 Radium. G. H. Stover.
43 Testing of Vision in Public Schools. Edward Jackson.
44 Testing of Hearing of Pupils in the Public Schools. Wm. C. Bane.
45 Tendon Losses. George W. Miel.

39. **Treatment of Neurasthenia.**—There is no specific for neurasthenia, according to Pershing. The resources for its treatment are limited to the use of remedies preventing loss of nervous energy, and prevention of emotional disturbances by reassurance and favorable suggestion; and inculcating the habit of muscular relaxation and repose, by limitation of work, prevention of toxic conditions, removal of peripheral irritations, reduction of cortical irritability by medicines, and securing sleep. Further, by remedies to increase the income of nervous energy by nutrition and drugs, as well as certain remedies used empirically, like hydrotherapy, electricity, massage, etc., whose action is complex or obscure. Emotional disturbances are the most serious causes of nervous weakness, and they can be helped by removal of the ideas which produce them, especially by voluntary suppression of motor reaction to small annoyances and anxieties and the cultivation of attitudes and actions which express serenity and repose. The prohibition of work is an obvious remedy, but in many cases it is advisable to keep the patient doing a reasonable amount and removing as far as possible every cause of exhaustion. The relative importance of work and worry as causes must be carefully considered in every case, and everyone should cultivate some occupation to crowd out inopportune thoughts. Pershing finds the uric acid diathesis a very frequent complication of neurasthenia, and, therefore, to be met. Intestinal indigestion is another, and the excessive use of alcohol can only aggravate the condition. Tobacco is a milder sedative and can sometimes be allowed, though many do badly with it. The pain and annoyance due to disease in any part of the body may be a contributing cause, and even when shielded from direct irritating influences they can not always be excluded, hence the advisability of lowering the sensitiveness and irritable weakness of the cerebral cortex. Codein and opium in small doses are suggested, together with other remedies, such as strychnin and laxatives taken at different times, the patient being strictly prohibited from having any knowledge as to the ingredients of the prescription and the size and frequency of the dose of opium. The latter is only a last resort and should not be prescribed when it is not absolutely necessary. Sleep should be secured as far as possible without the use of hypnotics. When one is used it should be omitted every second or third night, and altogether discontinued as soon as possible. Food should be abundant and taken at short intervals, rich in nitrogenous and phosphorized articles, but any anxious attention to the diet does nothing but harm. Strychnia and small doses of calomel and intestinal antiseptics are often of service, but the main thing is that the patient should eat without apprehension. Pershing speaks unfavorably of the use of phosphorus compounds for sustaining the nervous energy. Iron, arsenic and strychnia are sometimes useful. Such remedies as electricity, hydrotherapy and massage he places last because he considers them of least importance. Any or all of them may be used, especially for their physiologic effect, as an adjunct to other remedies. The real difficulty in treating neurasthenia is not to get remedies that may be used, but to select and make effective a combination which best suits the particular patient. We must select and emphasize some methods and ignore others. For some the Weir-Mitchell rest cure is advisable and to others it may do harm.

57 Remarks on Microbial or Mycotic Cystitis in Women. George T. Harrison.
58 *The Pelvic Musculature in Disease. Hugo O. Pantzer.

46. **Forceps Rotation.**—Wilson describes the mechanism of artificial rotation of the head in the occipito-posterior position, and remarks that the error in attempting to favor rotation of the head by the forceps by the usual method lies in the preconceived idea that in order to rotate the blades concentrically with the axis of the pelvis it is necessary to rotate the handles on their long axis. Tarnier has shown the dangers of this method, and that the blades will describe a cone of rotation,

the base of which is in the pelvis, and its diameter greater than the pelvic cavity. He recommends as a substitute for this the rotation of the handles in such a way as to permit them to describe a wide circle of revolution, leaving the tips of the blades as a fixed point. The mechanism of this is illustrated by Wilson, who remarks that the maneuver can be carried out as successfully with the Tarnier or Sympson forceps as with the ordinary obstetric forceps.

48. **Fetal Heart Murmurs.**—Wetherill and Hall report a case in which the fetal heart murmur was diagnosed before birth and attributed to *congenital pulmonic stenosis.*

49, 50 and 52.—See abstract in The Journal, xli, p. 980.

53.—Ibid., p. 981.

55. **Cancer of the Cervix.**—The method developed by Byrne of treating cancer of the cervix with the thermocautery is described here by Chase. The objections to the powerful chemical caustics are the pain they produce and the difficulty of limiting the area of destruction, but it is quite exceptional for the patient to suffer pain after the use of the thermocautery, provided the mucocutaneous surfaces are not seared or burned. He usually finds it easy to protect the vaginal surfaces by the use of strips of asbestos paper of proper size. With large areas of ulceration the curette may be first used, and may cause considerable hemorrhage, but this is controlled by adrenalin or pledgets dipped in dilute acetic acid, applied with pressure. After this the cautery knife is applied at a dull red heat until the surfaces are thoroughly charred. The after-dressing consists of a 5 per cent. iodoform gauze, reapplied daily, after cleansing of the parts with peroxid of hydrogen. Great gentleness in manipulation is necessary, and the use of the bivalve speculum should be avoided. The Sims speculum and the Sims position are usually the best, the only exception is where the posterior vaginal wall is involved. The slough usually separates in one to two weeks. Dressing should be daily until healing follows, or, should it fail, the part should be kept as aseptic as possible. As in granular surfaces generally, the recognized healing power of nitrate of silver must not be forgotten. In some cases the thermocautery may have to be repeated at intervals of several months. He gives cases illustrating the results of treatment, and remarks that this method is not suggested to supersede radical treatment, but rather as applicable in postoperative cases on recurrence, in cases which have passed the stage for successful attack, or if the patient refuses heroic treatment.

56. **Hysterectomy.**—Deaver favors the abdominal route as offering increased space for manipulation, greater security against hemorrhage and less chance of injuring the ureters. He does not think it necessary to dissect out the iliac glands, as the additional mortality from the operation is not balanced by the lessened liability to recurrence. His technic is that of others, with slight modifications.

58.—See abstract in The Journal, xli, p. 980.

## Annals of Surgery, Philadelphia.

*January.*

59 *Removal, After Suprapubic Cystotomy, of the Prostate and of the Prostatic Urethra for Senile Enlargement of the Prostate. B. G. A. Moynihan.

61 The Mixed Tumors of the Salivary Glands. (To be continued.) Francis C. Wood.
62 Excision of Tuberculous Mass from Liver. Robert R. Rome.

59. **Removal of the Prostate.**—During the past two years Moynihan has operated on 12 cases for removal of the prostate and the prostatic urethra. His first operation was done in 1901, and was in a measure accidental. He was somewhat fearful that the ultimate issue of the operation would be unfavorable, but the results were good. The operation is performed suprapubically, a provisional stitch securing the opened bladder to the parietes on each side; the prostate being pressed upward by rubber-gloved fingers in the rectum, while the stripping is done with the finger of the other hand through the suprapubic opening. The operation is an easy one if done under proper conditions. The catheter is passed after the removal of the organ, and the bladder freely flushed with hot, sterile saline solution or a hot 1 per cent. solution of carbolic acid. When the fluid returns almost clear, a large rubber tube is passed into the bladder, and a couple of stitches introduced into the wound. There are often severe paroxysms of pain for a few hours after the operation, but they are relieved by morphin. At the end of forty-eight hours the tube is removed from the bladder, and the patient allowed to sit up with a bed rest. On the fourth day and each succeeding day a catheter is passed and the bladder freely washed with dilute carbolic acid lotion. On the seventh day the catheter is tied in and a drag placed on the suprapubic wound, which is removed every morning and the bladder again flushed. The catheter is not removed for five or six days; a new one is then introduced. The patient is allowed to get up and sit in a chair at the end of the first week if he is a feeble old man. The urine ceases to come through the wound about the end of the third week, and at the end of the fourth or occasionally not until the end of the fifth, the patient is passing urine spontaneously at natural intervals and the wound is entirely closed. If there has been a cystitis, he orders urotropin or helmitol, 10 to 15 gr. doses three or four times daily. He tabulates his twelve cases.

60. **Typhoid Perforation.**—Harte and Ashhurst's review is complete. They consider that perforation occurs in an average of about 2 per cent. of cases. They analyze statistics as to location. In over 73 per cent. of 190 cases where the site was mentioned, it occurred within twelve inches of the cecum and in only 4 cases more than three feet distant from the ileocecal valve. The authors conclude that operation rarely hastens death, and the proportion of cases that finally left the surgeon's hands well was 20 per cent. The rarity of recovery without operation does not justify any other course than laparotomy. General anesthesia is usually justifiable, and rapidity of operation is important. The incision is best made to the right of the median line, over the cecal region, and need not average more than four inches, though with very fat abdominal walls it may have to be extended from the edge of the ribs to the symphysis. The authors prefer the incision through the outer half of the right rectus muscle; it is straight, simple, avoids better the deep epigastric artery, and the cecum is more readily located. Excision of the ulcer they consider useless and harmful. Black silk is the best material for intestinal suture. They usually prefer a row of mattress sutures parallel to the long axis of the gut, crossing the longitudinal Peyer's patch at right angles. A second row of Lembert sutures, likewise applied longitudinally, but continuous, is also employed, and these are usually sufficient. They avoid sutures transverse to the long axis. The toilet of the abdominal cavity should be thorough to combat the peritonitis, and a large tube half an inch in diameter, with multiple perforations, should be introduced through the wound, a rubber tube and a funnel being attached to its outer end, and through this should be poured gallons of hot solution. The success depends more on the quantity than the quality. The temperature should be at least 110 F. The tube should be carried around to the various parts of the abdomen so, as to thoroughly irrigate every portion, and the douching continued until the return fluid is clear. Drainage is necessary in nearly every case. They prefer gauze drainage, but see no advantage in the iodoform or medicated gauze. Hyperdermoclysis or intravenous infusion is wise. Nourishment must be given, but all food by the mouth avoided as long as possible. After twenty-four hours a teaspoonful of hot water may be given by the mouth every ten or fifteen minutes, but no food until the third or fourth day at least, nutritive enemas being continued. After the third or fourth day the surgeon should begin to think of removing the gauze drains, but there is no hurry, and they can be allowed to remain longer if there is any doubt. They should be well moistened with salt solution or hydrogen peroxid and given time to absorb it, and the utmost gentleness be used in removing them. When the gauze has been removed it requires nice judgment to know how much to replace; a residual abscess on the one hand and slowness of healing on the other, are to be avoided. A fecal

**1. Interpretation of Findings with Urine Divisor.**—Cathelin enumerates several points learned by study of the results of the use of his "intravesical graduated divisor." In 50 cases it demonstrated that the symptoms observed could not be referred to the kidneys, but were due to some neighboring organ. He found that cystitis did not render the urine turbid when the kidneys were sound and the urine was withdrawn at once. In 3 out of 12 cases of hematuria, each kidney emitted bloody urine. In 10 cases of movable kidney the proportion of urea was less in the urine from the much-displaced organ.

**4. Treatment of Wounds of the Kidney.**—Boari's experience in the clinic and in experiments on dogs has convinced him that the kidney is remarkably tolerant of injuries such as stab wounds. Surgical intervention should, therefore, be conservative. The most serious injuries are those in which the pelvis is involved, as repair proceeds less rapidly and effectually in the tissues of the pelvis.

**5. Retrograde Cystoscope.**—Schlagintweit's instrument has a small reflecting prism between the light and the lenses. This prism fits in the shaft of the cystoscope. After the instrument has been introduced into the bladder, the prism can be raised out of its bed to any height desired, and reflects into the lens the parts of the bladder interior not visible by direct inspection.

**9. Diagnosis of Calculi in Kidney or Ureter.**—Guyon comments on the remarkable tolerance of the kidneys and ureters for hard foreign bodies in contrast to their extreme sensitiveness to distension. Renal colics become valuable for the diagnosis of calculi when they are habitual and are unmistakably influenced by movement and repose. Calculi are liable to exist without causing pain on pressure or reflex pain. Hematuria induced by exercise is a valuable sign of a calculus, especially when accompanied by pains aggravated by the same factors.

**10. Curability of Tuberculosis of Bladder.**—Motz has witnessed 8 cases of complete recovery from a tuberculous bladder affection. One patient was curetted and 5 per cent. guaiacolated oil was instilled; another was treated with instillations of a 1/5,000 bichlorid solution. The others recovered without local treatment, after removal of the tuberculous kidney by nephrectomy or its exclusion by obliteration of the ureter. In 2 cases the affection was so severe that recovery had been considered hopeless. The urine contained abundant tubercle bacilli. No case of bladder tuberculosis should be considered hopeless after these experiences. The general condition should be improved by every possible means, and the fact should be borne in mind that tuberculosis of the bladder is very rarely primary. If the kidney is the primary source, its prompt removal will prevent reinfection of the bladder. Even an extremely severe bladder affection does not contraindicate nephrectomy in such cases. The bladder tuberculosis will probably retrogress, but no instance is on record of the cure of a clinically manifest tuberculosis of the kidney except by ablation of the organ affected. If the prostate and seminal vesicles are infected with tuberculosis they should be examined at brief intervals to discover a tendency to heal—which is a frequent occurrence. If not, and the lesions commence to soften, the irremediable destruction of the neck of the bladder should be forestalled by suppressing the focus at once and completely. His patients were 4 men and 4 women, the ages 15 to 45. The particulars of each case are detailed.

**14. *Ablation of Female Urethra.***—Legueu's patient was a woman of 63 with tuberculous lesions of urethra and bladder. The tumor in the urethra had been diagnosed as cancer and had been twice ablated. The anterior urethra was then removed to prevent further recurrence. The various steps of the operation are illustrated. The patient, like others of the same category in the literature, is continent, except when laughing or exerting herself.

**15. Chronic Cystitis.**—After discovery and removal of the cause and resistance to instillation of nitrate of silver, the surgeon should not hesitate to curette and cauterize through a hypogastric incision. During the entire course of treatment urotropin should be administered to protect the ureters and kidneys from possible ascending infection.

**18. Blennorrheal Urethritis.**—Rychner states that in 22 cases treated with ichthargan, every patient was cured who completed the specified course of treatment. He gives the methods. Internal dosage of the drug was useless.

### Revue de Gynécologie, Paris.

22 *Kystes hydatiques du ligament large et du grand épiploon. M. Savariaud.
23 *Choked Hernia. P. Nau.—L'engouement herniaire.
24 *Du traitement chirurgical des collections purulentes dans le lobe droit du foie (in right lobe of liver). H. Maasland (*Hague*).

**20. Tuberculosis of Vulva.**—The hypertrophied tissues in the vulva in the case described suggested elephantiasis, and the discovery of their tuberculous nature, with the presence of tubercle bacilli, was a surprise. Poeverlein has recently reported a similar case in his thesis at Munich. The patients were 31 and 49 years old, and the course of the affection was slow and chronic with no appreciable effect on the general health. Both cases were treated by extensive excision, repairing the defects as well as possible, and the immediate results were excellent.

21. **Double Uterus.**—There are seven types of a double uterus, as Ombredanne shows by diagrams and cuts of 2 cases personally observed. One belonged to the type in which both fundus and cervix are distinctly double, the other to the type in which the cervix of each uterus blends into a single large one. The literature is reviewed and the indications for operation on these deformities. Total hysterectomy is preferable to supravaginal amputation in such cases when surgical intervention becomes necessary for any cause. The only exception in case of bilateral annexitis would be if the broad ligament were found prominent, which is exceptional.

22. **Hydatid Cysts of Broad Ligament and Greater Omentum.**—Savariaud urges search for further tumors in operating on a hydatid cyst in the peritoneum of the Douglas cul-de-sac or the broad ligament. The latter rarely occur singly. He describes a case and extols the advantages of the abdominal route in operating on such cases.

23. **Choked Hernia.**—Nau analyzes 23 cases found in the literature in which a hernia had become obstructed by fecal masses; 5 in which the herniated loop had been choked by *helminths;* 3 in which a diverticulum was involved, and 4 of obstruction by a foreign body. The symptoms of obstruction of the herniated loop from these causes are milder than those observed in a strangulated hernia. The indolence of the tumor and the consistency of its contents are characteristic. Taxis must not be blind. By discriminating palpation it may be possible to differentiate the obstruction and massage it away in case the loop is absolutely intact. If not, treat it like a strangulation.

24. **Surgical Intervention on Right Lobe of Liver.**—Maasland has operated on 6 patients presenting an accumulation of pus in the right lobe of the liver. He is convinced that an individual with an abscess of the liver should be warned against living in a tropical climate. He has in several instances sent a nearly cured patient back to Europe, where the change of air completed the cure. If, however, the improvement encouraged them to return to the East Indies or other tropical clime, the suppuration recurred with increased intensity. Many cases are diagnosed malaria, but their lack of response to quinin differentiates them. Puncture of the liver is liable to be dangerous. One of his patients succumbed to hemorrhage into the abdominal cavity after the fifth puncture. Maitland and others have also published cases of fatal hemorrhage after puncture.

30 *Valeur et signification de l'hyperchlorurie au cours des pleurésies tuberculeuses. E. Micheleau.
31 La réciprocité dans la pathologie. S. Laache.

25. **Duodenal Ulcerations in Bright's Disease.**—Devic and Charvet have discovered ulcerations in the duodenum at the necropsy of 12 subjects with Bright's disease. Nothing in the clinical course had suggested these ulcerations, except melena a few days before death in a single instance. They are evidently among the complications to be expected in advanced stages of chronic kidney affections, and are probably usually overlooked in the clinic and at the necropsy. There was concomitant scoliosis in 3 of the cases described. The ulcerations display a tendency to burrow deep, with no effort at repair.

26. **Permeability of the Kidneys in Disease.**—Bernard's conclusions of this comprehensive study are to the effect that chronic interstitial nephritis is characterized by an early and constant impermeability of the kidneys, which is compensated at first by polyuria. In epithelial nephritis, on the other hand, accompanied by its edema and albuminuria, the kidneys are permeable, at least in the more rapidly fatal forms. In the protracted cases the kidneys become less permeable in the second stage. This difference in the permeability in the interstitial and the epithelial forms is revealed by the changes in the freezing point of the blood. Further research is needed on the permeability of the kidneys in various kidney affections other than Bright's disease (urinary, cardiac, diabetic, etc.). It may compel a revision of the theories in regard to the pathogenesis of uremia, and also enable us to classify the symptoms of renal origin according to the functional disturbance which is engendering them. The application of the functional tests has already shown that the cardiorenal type may be separated into two groups, the cardiac and the nephritic group, each recognizable by the characteristic permeability. He regards cryoscopy and the methylene blue test as the most reliable measures for estimating the kidney functioning, and describes their application in 30 cases.

27. **Typhoid Myelitis.**—Lépine's patient succumbed in about six weeks after the first symptoms of typhoid fever. Evidences of paralysis of the legs were noted by the second week, progressing to paraplegia in a few days. The lesions found at the necropsy were those of an acute anterior poliomyelitis of the lumbosacral region, with central myelitis and lesions of the white matter and leptomeningitis. They were probably due to the typhoid toxins, as no bacilli were found in the parts. Reviewing the literature, he finds that this typhoid myelitis is not always, but usually, fatal. Even if the patient recovers, he remains exposed to the eventual consequences of the past toxic action, entailing later possibly sclerosis in patches, chronic myelitis or tabes.

29. **Plastic Linitis.**—Hoche relates the clinical course and illustrates the pathologic anatomy of 5 cases of fibrous infiltration of the areolar network surrounding the vessels of the stomach. They show that this plastic linitis may be merely a connective-tissue lesion, or a hybrid connective tissue and epithelium lesion, in which either may predominate. The term spastic linitis is general, and should be supplemented by some word descriptive of the type as he sets forth in detail.

30. **Hyperchloruria in Tuberculous Pleurisy.**—Micheleau has been studying the demineralization of the organism in the course of tuberculosis. He found distinct excessive elimination of the chlorids in the urine in 17 out of 22 cases of tuberculous pleurisy, especially marked during the period of absorption. The 5 cases free from hyperchloruria were those in which recovery was most rapid. His experience indicates that it may be accepted as a sign of the tuberculous nature of the pleurisy and also of the tuberculization of the organism.

42 *Tuberculose und Gravidität. W. Hahn.
43 Ueber Bismutose als Darm-Adstringens. P. Cohnheim (Berlin).

33. **Artificial Wave and Spring Baths.**—Höglauer of Munich has devised a system of waves in the bath water, produced by the action of a wheel driven by electricity. Meyer has been trying these new wave and spring baths, as they are called, in the hydrotherapeutic treatment of neurasthenic and obese subjects and those with constipation on a nervous basis. The influence of the gentle massage induced by the commotion of the water had an unmistakable favorable action. Patients with rheumatic pains were also benefited by them. The water is forced up through a dozen openings in the double

bottom of the tub for the spring baths. Both forms are illustrated.

34. **Experimental Diagnosis of Renal Tuberculosis.**—Salus advocates subcutaneous inoculation of guinea-pigs with the sediment of the sterile, centrifugated urine as the best mode of confirming the diagnosis of a tuberculous renal affection. He found that the urine contained traces of albumin in 44 per cent. and formed elements in 51 per cent. of 27 cases of a known tuberculous process elsewhere than in the kidneys. There is also a possibility that tubercle bacilli might find their way into the kidneys from the circulation or diseased tissues without an actual tuberculous renal affection, consequently the discovery of abnormal conditions in the urine does not inevitably indicate a local kidney affection. It may, however, confirm the existence of a tuberculous lesion somewhere in the body.

35. **Cyclic Albuminuria.**—Hauser has had 14 cases under observation for years, and has become convinced that this condition is due to the relics of some preceding infectious disease still persisting in the kidneys. It is therefore a persisting, unhealed nephritis, and is especially prone to occur after scarlet fever. Treatment includes prolonged rest in bed, exclusive milk and vegetable diet kept up for a long time, copious diuresis by means of mineral waters to ensure the thorough rinsing out of the kidneys, with systematic training of the kidneys to accustom them to a gradually increasing amount of work. He was able to cure nearly all of his patients by this technic, but at the same time he warns that in a certain proportion of these cases the cyclic albuminuria is due to an absolutely incurable nephritis. Relapses are also frequent.

36. **Musical Pulse Register.**—Sommer describes and illustrates an apparatus that he has invented by which the sphymograph index works on a small, primitive wind instrument, emitting a constant musical tone. The variations in the pulse rate raise or lower the note, and with a corresponding tempo. By this acoustic method it is possible to detect and study irregularities in the rhythm better perhaps than by the other methods in vogue.

40. **Attempts to Inoculate Apes with Syphilis.**—Lassar reports that he repeated the experiments of Roux and Metchnikoff on a chimpanzee, striving to inoculate it with syphilis. Most of the points where the syphilis virus was introduced rapidly healed, and only on the brow two ulcers developed which slowly retrogressed after a few weeks. A papulous affection was also observed on the palms and soles and the animal shed some of its hair. It is possible that these results indicate an abortive form of syphilis, but Lassar thinks that considerable good will is required to accept them as such. In a second animal an ulcer developed which likewise bore considerable resemblance to the primary syphilitic lesion, as can be seen from the cuts.

41. **Indications for Removal of Spleen.**—The enlarged spleen of leukemia should never be removed, Jordan thinks, but under other conditions the prognosis of splenectomy is good. He has performed the operation in 7 cases, and all the patients but 1 recovered. In the 17 cases of Banti's disease in which the spleen was removed, 14 of the patients recovered. Splenectomy is justified in certain cases of malaria. The mortality is constantly diminishing.

42. **Tuberculosis and Pregnancy.**—Hahn regards pregnancy as a serious complication of tuberculosis, but thinks that after the fourth month there is nothing to be gained by induction of abortion in comparison with allowing the case to go on to normal term. Conception should be prevented in tuberculous women, but he does not advocate systematic interruption of a pregnancy.

52. **Active Principles of Adrenal Gland.**—Abbott found that the removal of the hemolytic receptors out of the serum of rabbits previously injected with adrenal substance from guinea-pigs, prevented any hemolytic action on the blood of these animals. The corpuscles in the blood of the guinea-pigs remained intact after removal of these receptors, while they were rapidly destroyed by the action of the whole serum. His research was published in this country last year.

56. **Spore Threads for Tests of Disinfection.**—Kokubo recommends to dry the threads at room temperature and keep them in a dark place, when they are ready for use at any time.

59. **Radium Burns.**—A small box with a mica cover, containing 75 mg. of radium, was fastened on Goldberg's arm and left there for three hours. No effect was apparent until four days later when a red patch developed about the size of the box cover. This became transformed into a necrotic ulcer by the fourteenth day, spreading until it presented the aspect of a serpiginous ulcer, and four other ulcers developed at different points on the arm, passing through the same phases from the red patch onward. A similar patch developed further on the chin, groin and hand, terminating likewise in necrosis of the corium. The healing process commenced first in the later patches. At the date of writing, the first patch still presents an atonic ulcer, gradually healing and only half as large as it was at one time. The action of radium is proportional to its radio-activity and not to its bulk. Further experiments on animals showed that a lump of 75 mg. was much less effective than another weighing only 30 cg. The entire process runs an almost painless course. The exposure and all the subsequent phenomena were painless. The necrosis develops without fever, and the ulcer has a peculiarly torpid character. In 2 cases of ulcus rodens of the nose or cheek, treated by half-hour exposure to the radium once a week, the lesion gradually healed by a process of evident sclerosis. By the end of two and a half months the cosmetic results were most excellent. One of the patients, thus treated for a total of four and one-half hours, has nothing left of the ulcer except a lighter-colored patch of skin and slight depression. The

facts observed suggest that there are other rays involved besides the true Becquerel rays. The portability, easy dosage and remarkable localized action render this new therapeutic agent, the writers conclude, a pre-eminently valuable addition to the therapeutic arsenal.

71. **Leucocyte Count in Gynecology.**—Dützmann reports 223 cases in which 2,000 counts were made. In 90 pus was revealed by this means when the probabilities were against its existence by other tests, even palpation in narcosis. He concludes from his experience that in cases of exudate formation with suppurative breaking down, the leucocyte count may impart invaluable information. It is also important for differentiation of suppurative and non-suppurative affections of the adnexa and also as a guide to the choice of the vaginal or abdominal route. Hyperleucocytosis in cases of myoma, carcinoma or tubal pregnancy is sometimes the only sign of an unsuspected accumulation of pus. The leucocytes do not increase in number in case of tuberculous suppuration and only slightly with gonorrheal. He found a marked hyperleucocytosis accompanying torsion of ovarian cysts with peritonitic lesions, but no pus. In sepsis the leucocyte count may sometimes possibly indicate the proper moment for intervention, as diminishing numbers show that the resisting forces are weakening. The leucocytes behave in eclampsia the same as in sepsis, which is additional testimony in favor of the assumption that it partakes of the nature of an infectious disease. The iodin reaction of the leucocytes in case of suppuration will sometimes confirm the diagnosis suggested by the leucocyte count.

73. **Treatment of Puerperal Fever.**—Bennecke's review of recent endeavors in the treatment of puerperal fever seems to justify the attempt to save life by radical surgical intervention in the rare very severe cases. The majority, however, respond sufficiently to internal medicine, with serum treatment and various chemical-biologic measures. The prospects for the latter are becoming more and more promising.

74 and 75. **Staphylomata in Cervix and Uterus.**—Peham's patient was a young nullipara who required repeated intervention for the removal of a number of long, grape-like, pedunculated tumors which proved to be sarcomata. Some of them grew to be as large as a child's head. She succumbed to anemia in the course of five years, at the age of 24. Keitler reports the removal of seventeen sarcomatous polyps from the body of the uterus of a woman of 54. The organ was removed later. Peham's case is illustrated and the literature reviewed.

76. **Prevention of Perforation in Curetting the Uterus.**—Küstner describes 2 cases in which the omentum had plugged and healed a perforation made by a curette. He advises dilating the organ well before attempting to curette it, which can all be done at one sitting. The curette should have a graduated scale on it so that the distance in which it is inserted in the uterus may be constantly under inspection. This is especially necessary when used after an abortion and in case of carcinoma of the corpus. When part of the ovum is still retained and the uterus is large and soft, the fingers had better be used instead of the curette. Especial care is necessary in cases that have been previously curetted by others. In case of carcinoma, perforation should be immediately followed by removal of the uterus, but under other conditions compelling intervention he opens the abdomen and sutures the perforation.

85. **Radical Operation in Puerperal Sepsis.**—Asch has performed the radical operation in 10 cases after failure of all other measures. All but 3 of the women recovered from their desperate condition. He reviews the various indications for radical intervention, remarking that in case of saprophytic infection the focus usually remains limited to the uterus. Such cases only exceptionally require extreme measures. In case of streptococcus infection, abdominal intervention with drainage through the vagina is justifiable in advanced stages when convinced that the organism is unable to cope with the infection unaided. Such conditions are most liable to occur after criminal abortion and detachment of the placenta. When the infection has spread and induced abscesses in the parametrium—generally in this case through some rent in the perineum—the evacuation of the abscesses through the vagina should be first tried, with removal of the uterus by the same route as a last resort. The most serious mode of propagation of the infection is by way of the circulation, inducing thrombophlebitis. The thrombosed veins should be removed with the uterus. His conclusions are based more on the findings in patients who have died unoperated, than on his surgical experience. He is convinced that some of the fatalities might have been avoided by surgical intervention even very late.

86. **Treatment of Puerperal Sepsis.**—Rosenstein is inclined to ascribe great value to the silver salts in the treatment of puerperal sepsis. He thinks that as testimony accumulates in favor of the harmlessness of collargol we shall feel justified in injecting it still more freely and that the results will be much better. The results of treatment with nuclein combined with saline infusion, as practiced at Schauta's clinic and recently published by Hofbauer, are even more promising. Their effect is principally to attract the leucocytes, and the results were remarkably favorable. He mentions formalin injections as requiring further confirmation. In conclusion, he relates the history of a severe case with one or two chills a day and spleen much enlarged. Improvement was marked after injection of 10 gm. of a 1 per cent. solution of collargol, followed by 2 similar injections. Under their influence the spleen rapidly subsided to normal size. The improvement under collargol was unmistakable in this as in a number of other cases in his experience. The 3 injections were made in the course of eighteen days.

101. **Sublimate Injected Into the Kidney.**—The direct injection of a solution of sublimate into the parenchyma of the kidney of rabbits causes a deposit of calcareous salts around the spot.

103. **Hypoacidity of the Urine and Apparent Phosphaturia.**—Campani thinks that the presence of the earthy prosphates in large amounts in the urine is frequently not an indication of phosphaturia, but merely of insufficient acidity. This hypoacidity sometimes coincides with puberty and with venereal excesses. The mineral acids, especially hydrochloric acid, are the best means of combating the condition.

104. **Wire Joints.**—Pascale illustrates a case of a new shoulder joint reconstructed with wire after extirpation of the head of the humerus on account of sarcoma. Also a wire hip joint, inserted on account of subluxation and badly consolidated fracture of the neck of the femur. He also reviews the experiences of others in this line, and concludes that there is a promising future for such operations. It is possible by this means to reconstruct a joint with loops of wire. They are perfectly tolerated by the tissues even when the excursions are quite extensive. The wire not only fastens the bones together, allowing normal function of the parts by the new joint, but maintains the normal outline of the parts and thus favors muscular function and prevents atrophy. It also promotes the formation of new bone and regeneration of the tissues, directing and shaping the neoformation according to the normal type. He finds platinum the best metal for the wire, as it is extremely malleable and resistant. He prefers a double wire rather than a single wire of the same strength and size. The loop should be introduced to stay permanently, with no idea of removing it later. He gives cuts of his patients, one standing on and flexing the leg in which the hip joint is one of these wire ones. It is almost impossible to detect any difference between the aspect or functioning of the two sides. The results of such operations to date, although the number is very limited, are strong testimony in their favor. The literature on the subject is reviewed.

106. **Cataphoresis as Method of Local Treatment of the Stomach.**—Ferrannini announces that the direct application of electricity to the interior of the stomach, after ingestion of certain drugs, has a remarkable action on the absorption of the drug, hastening and intensifying its effect on the system. He calls this "local medication by cataphoresis." He uses an ordinary esophagus sound through which a wire is passed, terminating at the stomach end in a metal knob and connected at the upper end with the positive pole of the galvanic current, the negative pole being a large electrode applied to the epigastrium. The intensity of the current was not allowed to surpass 5 *milliamperes*, and the duration of the application not longer than five to ten minutes. He used for the tests a solution of .5 gm. potassium iodid in 500 gm. of distilled water, and then examined the saliva to detect the appearance of iodin. A number of tests were made on various subjects, always before breakfast to ensure similar conditions in each, and with and without the electricity on alternate days, for purposes of comparison. The results varied in different individuals. In one, the iodin reaction was obtained in the saliva four minutes after ingestion of the iodid when the current was turned on, but in tests without the current the reaction did not appear *until the tenth to the twelfth* minute. In one subject whose absorption was poor, the reaction appeared under the cataphoretic action in fifteen minutes, while without the electricity, twenty-five to thirty minutes always elapsed before the iodin could be detected in the saliva. In the clinic he found that strychnin and other drugs taken in half the usual dose, dissolved in a pint of water and followed by the cataphoresis, rapidly displayed the desired therapeutic effect, and frequently in subjects previously rebellious to the drug. The effect was also more durable. One patient with anachlorhydria who had been in the habit of vomiting every day for eight years and who had been treated in vain with all known measures, including strychnin and electricity in other forms, was rapidly restored to health by strychnin, supplemented by the cataphoresis. Equally remarkable results were obtained with atropin and cataphoresis in cases of hypersecretion and hyperchlorhydria.

130 Claudicacion funcional de las capsulas suprarenales. T. Suarez.
131 Quistes hidaticos del pulmon. R. Cabrera.

117. **Prognosis of Hydatid Cysts in Brain.**—Reggiardo gives numerous cuts of the findings in 3 cases of sudden death attributable to a hydatid cyst in the brain. *On this* basis and after analysis of the literature he concludes that death is inevitable in cases of a cyst inside a ventricle. The diagnosis of the intraventricular variety is suggested by the absence of localized symptoms, by the rapid development of the lesion, and by the extent of the paralytic phenomena. The prognosis

is also grave in case of periventricular cysts, but surgical intervention is indicated with some probability of success. The prognosis is still grave, but much less so in cases of paraventricular cysts, and intervention here should not be delayed an hour. As recovery in the latter case is possible, and as differentiation of the various forms is difficult, early exploratory intervention is justified in all cases, especially those with complex symptoms.

125. **Injection of Salt Solution to Avoid Vomiting in Laparotomies.**—Villanueva injects about 400 gm. of salt solution subcutaneously the day before he operates. In two years' experience with this measure he has found that it has a remarkable effect in reducing the tendency to vomit during or after the narcosis. He experimented on animals trying to discover a reason for this inhibiting action of the saline infusion, but was unable to discover the mechanism.

126. **Creosote in Tuberculosis.**—Cordero has been much impressed with the fine results attained in pulmonary tuberculosis by administration of large doses of creosote, part by the mouth and part by the rectum. In certain cases it is perfectly tolerated by the stomach and in progressive doses seems to display a direct and rapid action on certain forms of tuberculosis. He has given as much as 5 to 6 gm. a day by this dual route without inconvenience.

129. **Rubio's Gluteal Reflex: Sign of Hip Disease.**—The reflex mentioned is constant in case of incipient inflammation in or around the joint, but is never observed in hysteric or purely neuralgic affections. When percussion is applied with the fingers over the surface corresponding to the gluteus maximus, the gluteus and posterior muscles twitch as with an epileptoid tremor. The sign is most pronounced when percussion is applied at the point where the nerves pass through the sciatic notch, also along the course of the greater sciatic nerve. This phenomenon will invariably differentiate an inflammatory process from a purely nervous or hysteric affection. Acevedo has named this sign after the late Professor Rubio, as a tribute to his memory.

132 *Suprapubic Prostatectomy. Thornley Stoker.
133 *Prostatic Enlargement and Its Treatment by Freyer's Method Gilbert Barling.
134 *Anatomical Criticism of the Procedure Known as Total Prostatectomy. Cuthbert S. Wallace.
135 *Notes on Myiasis. P. S. Lelean.

132. **Suprapubic Prostatectomy.**—Stoker's method is practically the same as that of Moynihan noticed in THE JOURNAL of February 20, ¶59, p. 559. He details the method, the use of the suture through the parietal walls and bladder at the suprapubic opening to prevent any perforation of the peritoneal sac and to keep the opening of the bladder accessible. In performing suprapubic cystectomy he says the endeavor should be to make a wound with its apex at the bladder and its base at the skin surface. As a rule, it should not be closed or sutured except by the solitary suture he employs. There is likely to be considerable clotted blood in the bladder two or three days after the operation. It is usually best to let this alone, as its presence seals the large veins about the prostatic area and limits the tendency to bleeding and septic absorption. The urine also rapidly disintegrates the clots, and they are usually soon gotten rid of without effort. He never uses more than the most gentle syringing for several days after suprapubic operations. He thus classifies prostatic enlargements:

> 1. A true hypertrophy of the gland without any interstitial growths. 2. The existence on and within the substance of the prostate of one or more encapsuled tumors, distinct from the substance of the gland proper, and either myomatous or adenomatous in structure. Both forms of neoplasm or one only of them may be present. 3. A mixed condition of true hypertrophy and interstitial growths of the second class. This is much the most common. The tumors may eventually reduce the prostate to a state of pressure atrophy, or cause it to become a mere capsule for adventitious growths. It is the latter condition which, in all probability, has given rise to so much dispute and uncertainty as to the true pathology of enlarged prostate.

133. **Freyer's Operation.**—This term is sometimes used for the suprapubic method introduced by Freyer and described by Barling. He explores the prostatic region with a Ferguson's speculum after opening the bladder. In the operation he differs from Stoker in advising that in the prostatic capsule the incision need only pass through the mucous membrane and not also involve the gland as Stoker recommends. The value of the operation is marked in young prostatic subjects and where vesical stone is a complication. He reports in detail a number of his cases, and concludes that it is possible to enucleate the prostate and that the prostatic urethra is almost invariably, if not always, removed with the organ. If it were left it would necrose from want of blood supply. Its removal does not cause stricture. The operation gives excellent results, often restoring the function of the bladder to an absolutely normal condition.

134. **Anatomic Criticism of Total Prostatectomy.**—Wallace's conclusions are that the usual form of prostatic enlargement is an adenomatous one and that adenomatous tissue may surround the urethra or form masses in the lateral parts of the organ, behind the urethra, or in all three parts. The parts removed may consist of adenomatous masses from the lateral parts or of an adenomatous formation completely surrounding the urethra. He thinks that there is always left behind a definite laminated envelope containing glandular tissue derived from the expanded outer portion of the organ and that the amount of envelope left on the surface of the tumor after removal depends on the depth at which the enucleating finger cleaves the envelope; that the rectovesicular fascia is not opened nor the prostatic plexus or veins injured. While it is possible to remove small adenomata from the central or lateral part of the prostate without extensively involving the urethra, yet this canal is removed *in toto* when adenomatous growths are extirpated in their envelope and the lateral walls come away adhering to the adenomata when these are of any considerable size. He suggests the use of the term "surgical capsule" to be applied to the envelope formed from the prostate by the expansion of the adenomata. It is a pathologic formation, and represents more than the outer non-glandular portion called the cortex by Mr. Shattock. Its presence causes the small amount of bleeding and absence of urinary extravasation. In fact, he says, in the so-called total prostatectomy the enucleating finger never passes outside the limits of the prostate.

135. **Myiasis.**—Some remarkable cases of dipterous parasite infection are recalled by Lelean. He describes a form of fly, parasitic in the human species, observed by him in northern Nigeria, and remarks on the difficulty of extirpating maggots in some cases. The vitality of some of them is such that they survived five minutes' immersion in pure carbolic acid.

## The Lancet, London.

*January 30.*

136 *Hysterical Skin Symptoms and Eruptions. Thomas D. Savill.
137 *Sanatorium Treatment of Pulmonary Tuberculosis. C. Theodore Williams.
138 *Relation of the Medical Practitioner to Preventive Measures Against Tuberculosis. Arthur Newsholme.
139 Note on the Probable Mode of Infection by the So called Filaria Perstans, and on the Probability that This Organism Really Belongs to the Genus Tylenchus (Bastian). H. Charlton Bastian.
140 *A Contribution to the After-history of Gastric Ulcer. James W. Russell.
141 Notes on a Case of Otitic Cerebellar Abscess: Extradural Abscess: Trephining Middle and Posterior Fossæ; Recovery. Percy Jakins.
142 *The Efficient Treatment of Cardiac Failure. Alexander Morison.

136. **Hysterical Skin Symptoms.**—Savill describes seven different kinds of hysterical skin symptoms: General pallor, attacks of flushing, localized patches of congestion, dermatographia, acroparesthesia, erythromelalgia, urticaria, erythematous and hysterical exudates and localized ischemia; the first three are peculiar to hysteria, the other four are more frequent in hysterical than non-hysterical subjects, but he considers them expressions of vasomotor neuroses plus toxemia. Among the co-operating causes he includes toxins of gastro-intestinal origin, articles of diet, traumatisms, toxins of insects, etc. In conclusion, he remarks on the resemblance of the skin to the central nervous system in embryonic origin

and its pathologic resemblances to certain disorders, as syphilis, for example.

137. **Tuberculosis.**—Williams discusses the sanatorium treatment, giving the details as to construction, methods of exercise, disinfection, hydrotherapy, sun baths, etc., and discusses the results with tabulated statement of the experience of the German and Swiss sanatoria. He thinks the sanatorium treatment may be expected to produce great improvement in all but the very advanced cases and its educational value must never be overlooked. We must not be satisfied, however, with the sanatorium treatment, but endeavor to discover every weapon in our war against tuberculosis.

138. **Prevention of Tuberculosis.**—*Newsholme insists on the importance to the community and to the individual of diagnosis before the bacilli can be found in the sputum. He thinks that compulsory notification is certain to come, though there are strong reasons against forcing such a measure at once.*

140. **Gastric Ulcer.**—Russell studied 89 cases of gastric ulcer, tracing the history of 47, with recent particulars of 16. During the seven and one-half years covered by his inquiry the direct mortality was 2.1 per cent.; while 4.3 per cent. died from intercurrent disorders; 42.6 per cent. recovered (unless later history disproves it); 27.7 per cent. had but one attack and 14.9 per cent. recovered after one or more relapses; 6.4 per cent. can not be as yet classified as recovered or continuous and may eventually fall into either class; finally, 44.7 per cent. were suffering from stomach symptoms of more or less severity at the last report; 14.9 per cent. of these having repeated and definite attacks with intervals of immunity and 29.8 per cent. suffering almost continuous pain. He thinks the last group affords some justification for the plea for more frequent operative interference in persistent cases, always providing that the mortality can be kept low.

142. **Cardiac Failure.**—The use of digitalis in full doses is advocated by Morison in proper cases of cardiac weakness. He would give under favorable conditions in ingravescent cardiac failure 15, 20, 25 or 30 minim doses in the adult, at four hours' interval until a definite effect is produced on the action, force and capacity of the dilated and failing heart. This may require a continuous administration in such doses of the combined tinctures of strophanthus and digitalis until 200 or 300 minims have been taken. He thinks there is no unjustifiable risk in this rapid method of containing cardiac control provided it is used in suitable cases. Defects in the right heart alone or cardiac failure from purely pulmonary causes tend to deplete the left heart. The left ventricle of a fatal pneumonia, if the muscle has any native vigor, is often small and contracted. It is the left ventricle of asphyxia in which true cardiac failure plays only a secondary part unless the heart is otherwise degenerated. Here the digitalis group should be used with great care if at all. Such drugs, if they increase the ventricular systole, lessen the absorptive power of the left ventricle at the same time by decreasing its capacity. He speaks well of venesection in cardiac failure as a temporary expedient for urgent irrigation.

### Indian Medical Gazette, Calcutta.

*January.*

143 *Doctors as Civil and Political Officers. D. G. Crawford.
144 *Resisting Powers of the Larvæ of Culicidæ to Desiccation. E. Jennings.
145 Malaria: as Seen in the Andamans Penal Settlement. (Continued.) Ernest E. Waters.
146 *"Liver Chill" as a Factor of Disease in the Tropics. (Continued.) A. E. Grant.
147 Diphtheria in the Madras Presidency. J. W. Cornwall.
148 Report of a Small Outbreak of Cholera in 10th D. C. O. Lancers (Hodson's Horse) in June, 1903. E. A. C. Matthews.

143. **Doctors as Civil and Political Officers.**—Crawford gives an interesting list and the history of a number of prominent officers of the Indian medical service who have taken high positions in civil and political life in *that country* and in conclusion mentions others not in that service who have likewise been prominent, including General Wood of this country. The article shows the ability of medical officers to meet the demand of even the highest non-medical positions when required.

144. **Hibernation in Mosquitoes.**—The term hibernation hardly correct for the tiding of mosquitoes over the hot seas but it appears to Jennings that they have a power of getti into the mud in the larval state and there passing the peri inimical to their breeding. He has himself not been able keep mosquitoes alive long without food or water, but he d not see how they can survive in certain parts of India oth than in the way mentioned. He has been able to exclude t egg stage and thinks that the larval condition must be t form in which they survive.

146. **Liver Chill.**—Grant calls attention to the danger sudden chill after exercise or overheating and the relations *moisture and dryness* to the condition. Where the atmo phere is hot and dry the danger of chilling is lessened, t use of flannel underclothing is also a valuable precaution. H says only experience can teach European residents in India th conditions under which they are in danger of chilling.

---

## Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sendin them. A selection from these volumes will be made for review, a dictated by their merits, or in the interests of our readers.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otology, Rhinology, Laryngology, Hygiene, and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia, with the Collaboration of Wm. Osler, M.D., Baltimore; John H. Musser, M.D., Philadelphia; Jas. Stewart, M.D., Montreal; J. B. Murphy, M.D., Chicago; A. McPhedran, M.D., Toronto; Thos. M. Rotch, M.D., *Boston*; *John G. Clark*, M.D., Philadelphia; James J.
